Movements. Migration patterns poorly understood. Nominat race possibly sedentary in parts of range, migratory in others, e.g. summer visitor to S Brazil (mid-Aug to mid-May) and Uruguay (Sept-Apr), casual visitor to Patagonia. Race *minor* possibly migratory; in Colombia, flocks noted Sept to late Nov in Santa Marta region, and Jul to late Oct in Meta.

Status and Conservation. Not globally threatened. In Trinidad, locally fairly common visitor, mainly Jun-Oct, though occasional breeding suspected some years; rare in Tobago with apparently no recent records; locally common in Colombia, often forming large flocks outside breeding season; widespread but local in Venezuela, numbers in both Colombia and Venezuela also bolstered by migrants from farther S; rare in Surinam, where possibly a migrant; widespread in Guyana; in Brazil, seasonally common Apr-Oct in Mato Grosso, locally common to abundant summer visitor, mid-Aug to mid-May, in Rio Grande Do Sul; generally rather scarce to uncommon in Paraguay.

Bibliography. Belton (1984), Beltzer *et al.* (1988), Brooks *et al.* (1993), Canevari *et al.* (1991), Chubb (1910), Contreras *et al.* (1990), Davis (1993), Dubs (1992), Ifrench (1991), Friedmann (1948), Friedmann & Smith (1950), Gilliard (1941), Haverschmidt & Mees (1994), Hayes (1995), Herklots (1961), Hilty & Brown (1986), Meyer de Schauensee & Phelps (1978), Narosky & Yzurieta (1993), Parker *et al.* (1982), de la Peña (1994), Remsen & Traylor (1989), do Rosário (1996), Schubart *et al.* (1965), Short (1975), Sick (1993, 1997), Snyder (1966), Stotz *et al.* (1996), Tostain *et al.* (1992), de Urioste (1994), Wetmore (1926, 1968b).

12

Subfamily CAPRIMULGINAE

Genus *EUROSTOPODUS* Gould, 1838

11. Spotted Nightjar

Eurostopodus argus

French: Engoulevent argus **German:** Argusnachtsschwalbe **Spanish:** Chotacabras Argos
Other common names: Spotted Eared-nightjar

Taxonomy. *Eurostopodus argus* Hartert, 1892, Australia, Aru Islands and probably New Ireland. Genus tentatively merged into *Caprimulgus* by one author, but this proposal has received very little support. Formerly listed as *E. guttatus*, but this name applies to *E. mystacalis*, of which it is a junior synonym. Birds of NW Australia formerly separated as *E. harterti*, those of Groote Eylandt as *gilberti*, and those of Banda Sea as *insulanus*, but variation appears to be limited and clinal. Monotypic.

Distribution. Most of Australia, but generally absent in coastal regions from C Queensland S to SE South Australia and Tasmania. Some birds winter N to Lesser Sunda and Aru Is.

Descriptive notes. 27–35 cm; male 81–132 g, female 75–123 g. Sexes similar. Upperparts greyish-brown speckled greyish-white; central crown broadly streaked blackish-brown edged tawny or buff; broad buffish nuchal collar; wing-coverts greyish-brown speckled greyish-white, boldly spotted buff or pale buff, prominent buffish line along scapulars; buff submoustachial stripe and large white throat patch; underparts greyish-brown spotted buff, becoming buff barred brown on belly and flanks. Both sexes have large white spot on four outermost primaries but lack white on tail. Iris dark brown, bill dark brown, legs and feet

brownish. Immature paler than adult, with smaller white spots on outer primaries; juvenile more rufous than immature. Variation clinal, birds becoming larger and darker to S. Voice. Song of male is a rapid series of ascending “whaw” notes followed by bubbling gobbles, given from ground. Alarm calls are deep barks or chirps; other calls include grunts, gurgles and pops; makes guttural hissing sounds during threat and defence displays; adult calls to offspring with low grunts, chick utters soft cheeps and trills.

Habitat. Mainly open woodland, savanna and grassland; forest and woods, mallee with eucalyptus, *Melaleuca*, *Myoporum* or *Allocasuarina*, acacia scrubland with sparse undergrowth, spinifex and tussock grassland, savanna woodland, and mangroves; prefers areas with sandy or stony ground and plenty of leaf litter. In N Australia, also low gravelly hills and ranges with rolling woodland and scrubland. On Aru Is, wintering birds frequent savanna, grassland and edges of rainforest.

Food and Feeding. Diet includes mantids, Orthoptera, bugs, lacewings, beetles, moths and winged ants. Forages in flight, often among trees and bushes, home range covering up to 1 km². Also catches prey by fluttering and hovering near vegetation and fires, or makes short sallies from ground; occasionally feeds on ground.

Breeding. Breeds Aug–Feb (possibly mainly Sept–Nov), though may not breed if preceding winter too dry. Usually single-brooded, occasionally double-brooded. Territorial, often occupying same territory for several years. Nest-site beneath tree or among stones, often near hilltop or on ridge, often close to previous year’s site; no nest, egg laid on leaf litter or bare soil. Clutch 1 egg, elliptical, glossy, and pale yellowish-green, yellowish-olive or olive-green, lightly spotted and blotched purplish-brown; probably both sexes incubate, possibly female during day with change-over at nightfall, incubation period possibly 29–33 days; adults threatened at nest-site perform defence or distraction display; chick semi-precocial, covered in reddish-brown or chestnut down, brooded by both parents, independent at c. 30 days of age.

Movements. Sedentary and locally nomadic in N, migratory and partially sedentary in S. Some S populations leave breeding grounds Mar (perhaps) to May, move N through C Australia (mainly May–Jun) and winter across N Australia from May to probably Sept. Overshooting and wintering birds also occur on islands in Banda Sea and nearby: Romang (Jul), Babar Is (Aug–Sept) and Aru Is (Apr–Sept). Return migration through C Australia Aug–Oct. N populations apparently move to well-drained, sparsely grassed hills and ridges during wet season (Nov–Mar) and return to lower-lying plains during dry season. Records from New Ireland in Bismarck Sea require further investigation. During migrations, often forms loose flocks of 10–15 birds.

Status and Conservation. Not globally threatened. Widespread but local throughout breeding range, preferring drier habitats than other Australian nightjars. Breeding territories of c. 1–2 ha and often c. 1–1.6 km apart. Few data on population levels, though 1 bird every 2 km between Normanton and Karumba, Queensland; 43 in 74 km between Roto and Mellelea, New South Wales; 9 in 13 km along Murrayville Track, Victoria; 11 in 80 km between Coolawanyah Station and Wittenoom, W Australia; local decreases by 1970’s noted in Wanjarri region of W Australia, and at Bendigo, Victoria. In Lesser Sunda, probably just a winter visitor in small numbers to Babar and Romang, though possibly under-recorded as formerly considered fairly frequent on Babar; probably also a winter visitor to Aru Is, vagrants possibly reaching New Guinea; doubtful old report from New Ireland. In Australia, potential threats include loss of suitable breeding habitat to agriculture; at night often killed by traffic on roads and tracks. Predators include feral and domestic cats, snakes and foxes. Present in several protected areas throughout range, including Wyperfeld National Park (Victoria), Round Hill Nature Reserve (New South Wales) and Two People’s Bay Nature Reserve (SW Australia).

Bibliography Barker & Vestjens (1989), Beehler *et al.* (1986), Blakers *et al.* (1984), Christidis & Boles (1994), Coates & Bishop (1997), Condon (1975), Dawson & Fisher (1969), Deignan (1950a), Higgins (1999), Johnston & Richards (1994), Lindsey (1992), Macdonald (1988), Pizzey & Doyle (1998), Rand & Gillard (1967), Robinson & Whitbourn (1961), Rose (1997a), Schodde & Mason (1981), Schodde & Tidemann (1986), Simpson & Day (1998), Strahan (1994), Tronson & Tronson (1987), White & Bruce (1986).

12. White-throated Nightjar

Eurostopodus mystacalis

French: Engoulevent moustac **German:** Bartnachtschwalbe **Spanish:** Chotacabras Bigotudo
Other common names: White-throated Eared-nightjar

Taxonomy. *Caprimulgus mystacalis* Temminck, 1826, New South Wales.

Genus tentatively merged into *Caprimulgus* by one author, but this proposal has received very little support. Formerly listed as *E. albogularis*, but name *mystacalis* has priority. Internal taxonomy worthy of further study; races *nigripennis* and *exul* may both be distinct species, with at least the former apparently differing vocally from nominate *mystacalis*. Three subspecies currently recognized.

Subspecies and Distribution.

E. m. nigripennis E. P. Ramsay, 1881 - N & C Solomon Is (including Bougainville).

E. m. exul Mayr, 1941 - New Caledonia.

E. m. mystacalis (Temminck, 1826) - E Australia, from Cape York Peninsula S through E Queensland and E New South Wales to E & CS Victoria; winters N to SC & E New Guinea.

Descriptive notes. 30–37 cm; male 98–145 g, female 140–180 g; *exul* 1 female 77 g. Sexes similar. Upperparts greyish-brown broadly streaked blackish-brown; buff or tawny-buff nuchal collar; wing-coverts greyish-brown, speckled greyish-white and spotted buff; scapulars greyish-white or greyish-brown, broadly bordered blackish-brown on outer webs; large white patch on either side of throat; underparts brown spotted rufous and greyish-white, becoming greyish-white barred brown on upper belly, rest of underparts buff or tawny-buff barred brown. Both sexes have wings regularly spotted and barred buff, white distal spot brown. Immature paler, more vinaceous, than adult. Race *nigripennis* smaller and slightly paler than nominate form, with tawnier nuchal collar and small white bands (not spots) on outer primaries, female tending to have buffish wing markings. Race *exul* extremely distinct: upperparts greyish-white streaked blackish-brown; wing-coverts greyish-brown speckled brown, broadly spotted whitish-buff; scapulars greyish-brown on inner webs, greyish-white on outer webs, broadly streaked blackish-brown in centre; similar wing markings to race *nigripennis*; no nuchal collar; breast brown, frosted greyish-white and greyish-brown. Voice. Song of male is a rapid, ascending bubbling, given from perches or in flight; female occasionally gives similar call; song of *nigripennis* described as similar to an axe hitting wood; calls include low croaks and coos, with guttural hissing sounds and barks given during distraction displays; chick gives cheeps and harsh “khaah” calls.

Habitat. In Australia, typically forest, especially eucalypt and dry sclerophyll forest, woodland, and dry, lightly forested ridges with sparse understorey; occasionally in heathland, sandy areas with thickets, or mallee scrubland. In N of range, also edges of rainforest, wet sclerophyll forest, open grassy country and borders of mangroves. In New Guinea, wintering birds frequent forest edge, savanna, scrubland, open grassland, gardens, secondary growth and marshland. On Solomon Is, usually on or near beaches and also on offshore islets. Recorded from sea-level to possibly 1650 m.

Food and Feeding. Feeds on moths, beetles, flying ants, bugs, Orthoptera and mantids. Forages in flight, usually hunting over forests, woodlands or trees, up to c. 50 m above ground. Also forages among trees and along forest edges, gulleys and streams, or makes flycatching sallies from perches or ground. Home range may be up to 100 ha or more. Often feeds on insects attracted to artificial lights.

Breeding. Breeds Sept–Feb (mainly Oct–Dec) in Australia, perhaps later in S of range, Oct–Nov on Solomon Is and possibly Aug–Sept on New Caledonia. May not breed if preceding winter extremely dry; in N Australia, some pairs may rear 2–3 young in a season when conditions ideal. Territorial, breeding territories usually 1 ha or less; nest-site usually in clearing, beneath tree, near burnt log or among rocks and stones, favourite sites on side or top of stony ridge; often breeds in same area for several years, sites within few metres of each other; no nest, egg laid on bare ground or leaf litter. Clutch 1 egg, elliptical, yellowish, buff or dark cream, spotted and blotched brown and black with underlying lavender marks, but egg of Solomons race *nigripennis* generally smaller, whitish or pinkish, and more heavily spotted; incubation usually by female during day, period generally 22–28 days; adults threatened at nest-site perform distraction display; chick semi-precocial, covered in chestnut or reddish-brown down; 1 chick made flight after 31 days.

Movements. Nominant race sedentary and partly migratory in N of range, migratory in S. On migration, often in loose flocks. In E Victoria, present Nov–Mar. S populations winter in N Australia and New Guinea. In NE Queensland, resident N of Townsville, but farther N on Atherton Tableland large numbers occasionally arrive, stay a few months and then depart. In SE New Guinea, winters (late Mar to Sept) W to Fly R and N to Astrolabe Bay. Possible vagrant reported as far N as Idenburg R in N Irian Jaya. Occurs as passage migrant through Torres Strait but recorded only Sept and possibly Oct. Race *nigripennis* on Solomon Is sedentary. Race *exul* on New Caledonia presumed sedentary.

Status and Conservation. Not globally threatened. Widespread and locally fairly common in E Australia; possibly rare to scarce winter visitor to New Guinea, though perhaps under-recorded. Race *nigripennis* probably not common on Solomon Is. Race *exul* not recorded since type specimen taken in Aug 1939 on coastal plains near Mt Panie, NW New Caledonia. On Australian breeding grounds, few data on changes in population levels, though now rare at Logan Reserve, SE Queensland, and at several sites on plains N & NW of Melbourne. Occasionally killed by road traffic at night; potential predators include snakes, foxes, dogs and feral cats. In SC New Guinea, regularly recorded at Wasur National Park.

Bibliography Barker & Vestjens (1989), Beehler *et al.* (1986), Beruldsen (1980), Blakers *et al.* (1984), Christidis & Boles (1994), Coates (1985), Condon (1975), Conole (1987), Diamond (1972), Elliot (1935), Evison & Daly (1995), Hadden (1981), Hannecart & Léotard (1983), Hicks (1988c), Higgins (1999), Hollands (1991), Kutt (1994), Lindsey (1992), Macdonald (1988), Marchant (1987), Mayr (1941b, 1945), McNab & Bonaccorso (1995), Morgan (1960), O’Brien (1990), Olsen & Hayes (1994), Pizzey & Doyle (1998), Rand & Gillard (1967), Rose (1973b, 1997a), Schodde & Mason (1981), Schodde & Tidemann (1986), Simpson & Day (1998), Strahan (1994), Stronach (1981), Tronson & Tronson (1987), Wood (1995).

13. Heinrich’s Nightjar

Eurostopus diabolicus

French: Engoulevent satanique **German:** Teufelsnachtschwalbe **Spanish:** Chotacabras Diabólico
Other common names: Satanic/Devilish/Diabolical/Sulawesi(!)/Kalabat Nightjar, Heinrich’s/Satanic/Sulawesi/Celebes Eared-nightjar

Taxonomy. *Eurostopus diabolicus* Stresemann, 1931, Kumarasot, 250 m, base of Klabat Volcano, north Sulawesi.
Genus tentatively merged into *Caprimulgus* by one author, but this proposal has received very little support. Affinities of present species uncertain, but may be most closely related to other forest nightjars, *E. papuensis* and *E. archboldi*. Monotypic.
Distribution. Sulawesi.

Descriptive notes. 26 cm. Male known only from field observations. Upperparts greyish-brown, speckled and spotted brown, buff and pale tawny; crown broadly streaked blackish, no nuchal collar; wing-coverts brown, spotted and ocellated cinnamon-tawny; scapulars blackish, ocellated cinnamon on feather tips; band around throat white in male, rich buff in female; underparts brown, barred and spotted cinnamon and pale buff, becoming pale buff barred brown on belly and flanks; tail very narrowly tipped buffish. Female has small whitish spot on third and fourth outermost primaries; perhaps also present in male. Iris dark

brown, bill blackish, legs and feet dark brown. **VOICE.** Song unknown. Unidentified nocturnal calls heard in Sulawesi include a double-noted “plop-plop” and a short, bubbling trill; flight calls may include weak screams, loud “whirrip” notes and soft churrs.
Habitat. Possibly restricted to primary forest in clearings and openings, or along roads, tracks and edges. Recorded in lowland forest, hill forest and montane forest, including lightly logged areas, between 250 m and 1735 m.

Food and Feeding. Feeds on insects. Forages in flight, hunting along edges of forests and forest roads.

Breeding. No information. Possibly begins laying in Mar.
Movements. None documented. Presumably sedentary.

Status and Conservation. VULNERABLE. Restricted-range species: present in Sulawesi EBA. Until recently, known only from type specimen, a female, taken in Mar 1931 from Kumarasot, at base of Kalabat volcano on Minahassa peninsula in N Sulawesi; not recorded again, despite many collecting expeditions and visits by ornithologists, until Jul 1993 when a nightjar, possibly this species, was seen at c. 1700 m in Lore Lindu National Park. Rediscovered in May 1996, when birds seen in primary forest on E slopes of Gunung Nokilalaki and W slopes of Gunung Korekatimbu, close to Lore Lindu; possibly seen within the National Park on several occasions since then. Probably a rare and local species threatened by deforestation; type locality now devoid of forest and almost entirely covered by coconut plantations, at least to c. 1000 m. Some of remaining forest on Sulawesi is protected within national parks such as Lore Lindu and may conceal further populations.
Bibliography. Andrew (1992), Anon. (1998d), Bishop & Diamond (1997), Catterall (1997), Coates & Bishop (1997), Collar & Andrew (1988), Collar *et al.* (1994), Holmes & Wood (1980), King (1994), Stattersfield *et al.* (1998), Stresemann (1931b), White & Bruce (1986).

14. Papuan Nightjar

Eurostopus papuensis

French: Engoulevent papou **German:** Papuanachtschwalbe **Spanish:** Chotacabras Papú
Other common names: Papuan Eared-nightjar

Taxonomy. *Caprimulgus papuensis* Schlegel, 1866, Salawati and the opposite coast of New Guinea. Genus tentatively merged into *Caprimulgus* by one author, but this proposal has received very little support. Formerly placed in genus *Lyncornis*. Birds of E New Guinea have been separated by some authors as race *astrolabae*. Monotypic.
Distribution. Lowlands of New Guinea; also Salawati I.

Descriptive notes. 25-27.5 cm; 80-81 g (female). Sexes similar. Upperparts brown speckled and barred greyish-brown, cinnamon and rufous, broadly streaked blackish-brown on crown; no nuchal collar; wing-coverts brown speckled, spotted and tipped tawny and buff; scapulars cinnamon-buff speckled greyish-brown, boldly spotted blackish-brown; large white throat patch; underparts cinnamon-rufous barred brown, becoming buff barred brown on belly and flanks; both sexes lack white markings on wings and tail. Iris dark brown, bill blackish, legs and feet blackish. Immature similar to adult, though often

slightly paler and more heavily spotted on head. **VOICE.** Song of male is a rapid “coo-coo-coo-coo”; calls include low, guttural chattering.

Habitat. Mainly lowland rainforest in openings, clearings and glades with good ground cover of second growth, from sea-level to 400 m.

Food and Feeding. Feeds on moths and other insects. Forages in flight, hunting in forest clearings and openings or above forest canopy. Also feeds by making sallies from ground.

Breeding. Poorly known. Possibly breeds Jun-Aug. Nest-site usually among undergrowth in small clearing; no nest, egg laid on bare ground or leaf litter. Clutch 1 egg, elliptical, pinkish-brown, heavily blotched dark and pale brown, with underlying grey patches; incubation apparently by female during day.

Movements. None documented. Sedentary.
Status and Conservation. Not globally threatened. Widely distributed throughout lowlands, but generally appears to be rather scarce; not studied and no available data on population trends. Regularly recorded at Jalan Korea, near base of Cyclops Mts (Irian Jaya) and in Lakemaku Basin (Papua New Guinea).

Bibliography. Andrew (1992), Bailey (1992), Beehler & Finch (1981), Beehler *et al.* (1986), Coates (1985), Hicks (1988a, 1988d, 1990), Mayr (1937b), Rand & Gilliard (1967).

15. Archbold’s Nightjar

Eurostopus archboldi

French: Engoulevent d’ Archbold **Spanish:** Chotacabras de Archbold
German: Archboldnachtschwalbe
Other common names: Archbold’s/Mountain Eared-nightjar

Taxonomy. *Lyncornis archboldi* Mayr and Rand, 1935, west slope of Mount Tafa, 2400 m, New Guinea.
Genus tentatively merged into *Caprimulgus* by one author, but this proposal has received very little support. Formerly placed in genus *Lyncornis*. Monotypic.
Distribution. Highlands of New Guinea.

Descriptive notes. 26-30 cm; 1 male 74 g, 1 unsexed c. 80 g. Sexes similar. Upperparts darkish brown spotted buff and greyish-white, crown often greyish-brown broadly streaked blackish-brown; indistinct pale greyish-brown nuchal collar; wing-coverts brown spotted cinnamon, buff and tawny; scapulars greyish-brown on upper half (not always visible) and blackish-brown distally, with cinnamon or buff spots on tips; underparts brown spotted buff or whitish, becoming buffish barred brown on belly and flanks. Both sexes have brown, unmarked wings; male has tail narrowly tipped greyish-white, female has buffish tips. Iris dark

brown, bill blackish, legs and feet brownish or dark grey. Juvenile generally white with blackish spots on upperparts. **VOICE.** Song of male is possibly a short, trilled “tchrrrt”; alarm calls of adult at nest are soft, liquid trills; when agitated, makes guttural hissing sounds.

Habitat. Montane forest with clearings and open areas of heath, at 1800-3225 m.
Food and Feeding. Diet includes moths, beetles, bugs and cicadas. Forages in flight, hunting in forest clearings and openings, or over grassy plains close to forest edges. Also forages by making short flycatching sallies from perches.

Breeding. Poorly known. Breeds Oct to early Dec throughout range. Nest-site on ground, or on bank or narrow ridge 1-1.5 m above ground; no nest, egg laid on leaf litter. Clutch 1 egg, white and unmarked; adults threatened at nest-site may perform distraction display.
Movements. None documented. Possibly sedentary.

Status and Conservation. Not globally threatened. Restricted-range species: present in West Papuan Highlands EBA, Adelbert and Huon Ranges EBA and Central Papuan Mountains EBA. Widely distributed in suitable habitat at high altitudes, but generally considered rare or uncommon, though possibly under-recorded.
Bibliography. Andrew (1992), Beehler (1978), Beehler *et al.* (1986), Bishop (1987), Coates (1985), Diamond (1972), Gibbs (1996), Gregory (1995c), Hicks (1990), Mayr & Rand (1935, 1937), Rand & Gilliard (1967), Ripley (1964a), Rowland, P. (1995a), Rowland, R. (1994), Schmid (1993), Stattersfield *et al.* (1998), Tano (1996).

16. Malaysian Eared-nightjar

Eurostopus temminckii

French: Engoulevent de Temminck **Spanish:** Chotacabras de Temminck
German: Temmincknachtschwalbe
Other common names: Malaysian Nightjar, Lesser Nightjar/Eared-nightjar

Taxonomy. *Lyncornis Temminckii* Gould, 1838, Borneo.
Genus tentatively merged into *Caprimulgus* by one author, but this proposal has received very little support. Formerly placed in genus *Lyncornis*. Taxonomy requires further study. Monotypic.
Distribution. Extreme S Thailand through Peninsular Malaysia to Sumatra (including Nias, Bangka and Belitung) and Borneo.

Descriptive notes. 25-28 cm. Sexes similar. Shows distinct “ears”; upperparts brown speckled buff, pale buff and cinnamon, crown boldly spotted with blackish-brown; thin buff nuchal collar; wing-coverts brown, speckled and spotted buff, pale buff, buffish-white, tawny and cinnamon; scapulars brown speckled buff and tawny, boldly spotted blackish-brown; white throat patch or white spot on either side of lower throat; underparts buffish, indistinctly barred brown; both sexes lack white markings on wings and tail. Iris dark brown, bill horn-coloured with dark tip, legs and feet dark brown. Immature rather similar to adult but

upperparts rather cinnamon or tawny and less heavily speckled, and has less buff on underparts. **VOICE.** Call is a whistled “tut, wee-ow” given in flight; no other vocalizations have been described.

Habitat. Typically open country, open scrub forest, riparian woodland and forest edge. In Sumatra, primary and secondary forest and areas of second growth. In Borneo, dipterocarp forest, alluvial forest, scrubland, grassland, grassy swampland and coastal vegetation. Generally a lowland species, though recorded from sea-level to 1065 m.

Food and Feeding. Diet includes beetles, moths and other insects. Forages in flight, hunting over open country, rice fields and cultivated areas, forest clearings, forest edge, water and estuaries, and along rivers.

Breeding. Surprisingly little known. Possibly breeds Jan-Jul in Malay Peninsula, Mar-Apr on Belitung I, Oct-Nov in Sumatra, and from Feb in Borneo. Clutch 1-2 eggs. No further information available

Movements. None documented. Sedentary.
Status and Conservation. Not globally threatened. Local and uncommon in S Thailand; common on Malay Peninsula, where occurs in Taman Negara National Park; fairly common in Sumatra, e.g. at Gunung Leuser and Way Kambas National Parks; locally common in Borneo, where occurs in Bako and Gunung Mulu National Parks (Sarawak).

Bibliography. Andrew (1992), Bucknill & Chasen (1990), Davison (1997a), Duckworth & Kelsh (1988), Holmes & Burton (1987), Lekagul & Round (1991), Lim Kim Seng (1992), MacKinnon & Philipps (1993), Madoc (1936, 1976), van Marle & Voous (1988), Marshall (1978), Medway & Wells (1976), Nash, S.V. & Nash (1985, 1988), Riley (1938), Round (1988), Smythies (1981), Vowles & Vowles (1984), Wells (1999), Wilkinson *et al.* (1991).

17. Great Eared-nightjar

Eurostopus macrotis

French: Engoulevent oreillard **German:** Riesennachtschwalbe **Spanish:** Chotacabras Orejudo
Other common names: Greater/Philippine/Giant Eared-nightjar

Taxonomy. *Caprimulgus macrotis* Vigors, 1831, Manila.

Genus tentatively merged into *Caprimulgus* by one author, but this proposal has received very little support. Formerly placed in genus *Lyncornis*. Internal taxonomy requires further study. Five subspecies currently recognized.

Subspecies and Distribution.

E. m. bourdilloni (Hume, 1875) - SW India.

E. m. cerviniceps (Gould, 1838) - Bangladesh and NE India E to extreme S China and S through Indochina to N Malaysia.

E. m. jacobsoni (Junge, 1936) - Simeulue I (off NW Sumatra).

E. m. macrotis (Vigors, 1831) - N & E Philippines (Luzon, Mindoro, Catanduanes, Marinduque, Samar, Leyte, Bohol, Dinagat, Siargao, Mindanao, Basilan).

E. m. macropterus (Bonaparte, 1850) - N & C Sulawesi, Talaud Is, Sangihe, Banggai Is and Sula Is.

Descriptive notes. 31-40 cm. Sexes similar. Shows distinct "ears"; upperparts brown speckled and spotted buff, cinnamon and greyish-white, crown boldly spotted blackish-brown; broad tawny-buff or buff nuchal collar; wing-coverts brown, speckled and spotted tawny, buff and cinnamon; scapulars brown, boldly spotted blackish-brown; large white patch, occasionally tinged buff, on either side of lower throat; underparts buffish, indistinctly barred brown; both sexes lack white markings on wings and tail. Iris dark brown, bill brownish, legs and feet flesh-brown. Races vary mainly in size and colour, although coloration in all subspecies extremely variable. **VOICE.** Call is a whistled "put, wee-oo" or "put, weew-oo", usually given in flight or from perches.

Habitat. Mainly forest: primary forest (often by rivers), secondary forest, edges and clearings, second growth, scrubland and wooded grasslands. Also more open country. Recorded generally from sea-level to 1000 m, but up to 1750 m on Sulawesi.

Food and Feeding. Diet is known to include moths, beetles, bugs and termites. Forages in flight, hunting over forest clearings, neighbouring grasslands and near habitation.

Breeding. Poorly known. Breeds Jan-May (mainly Feb-Mar) in S India and Jan-May in Malay Peninsula; in N Sulawesi, nest with egg in Oct, and species especially vocal Mar-May; fledgling immature seen in early Oct on Peleng (Banggai Is); no data from other regions. Nest-site often under thick bush or bamboo clump in lightly wooded country or bamboo jungle; no nest, egg laid on leaf litter or bare ground.

Clutch 1 egg, elliptical, creamy-white or deep

salmon-pink, marbled and blotched pale grey and reddish, especially around blunt end.

Movements. Most populations appear to be sedentary, but race *cerviniceps* local migrant to parts of NE India, arriving Aug, common until Sept, then disappears after rains.

Status and Conservation. Not globally threatened. Locally not uncommon in SW India; resident and locally migratory in NE India but rare in Bangladesh; resident in W Yunnan (S China); common in Thailand; not uncommon resident on Malay Peninsula; in past said to be locally common on Simeulue I, though no birds recorded during one-week visit in 1995; locally fairly common throughout Philippines; locally common and widespread in Sulawesi; fairly common in Banggai Is and Sula Is; possibly common throughout much of remainder of distribution. Throughout its extensive range, species occurs in several protected areas, e.g. Periyar National Park (S India), Khao Yai and Kueng Krachan National Parks (Thailand) and Nam Bai Cat Tien National Park (SC Vietnam); also Dumoga-Bone National Park (NE Sulawesi), where up to 10 birds heard and seen simultaneously over park headquarters in 1980's.

Bibliography. Genus *NYCTIDROMUS* Gould, 1838

18. Pauraque

Nyctidromus albigollis

French: Engoulevent pauraqué **Spanish:** Chotacabras Pauraque
German: Pauraquenachtschwalbe
Other common names: Common Pauraque, White-necked Cuckoo

Taxonomy. *Caprimulgus albigollis* J. F. Gmelin, 1789, Cayenne. Seven subspecies recognized.

Subspecies and Distribution.

N. a. insularis Nelson, 1898 - Tres Marias Is (off W Mexico).
N. a. merrilli Sennett, 1888 - extreme S USA and NE Mexico.
N. a. yucatanensis Nelson, 1901 - W & E Mexico S to Belize and C Guatemala.
N. a. intercedens Griscom, 1929 - S Guatemala S to Costa Rica and W Panama.
N. a. gilyus Bangs, 1902 - Panama and N Colombia, perhaps to W Venezuela.
N. a. albigollis (J. F. Gmelin, 1789) - E & S Venezuela, Trinidad, the Guianas, N & NE Brazil; also (possibly this race) E & S Colombia and Ecuador S to N Bolivia.
N. a. derbyanus Gould, 1838 - C & S Brazil S to NE Argentina.

Descriptive notes. 22-28 cm; male 44-87 g, female 43-90 g. Sexually dimorphic. At rest, wing-tips reach half-way along tail. Upperparts greyish-brown tinged rufous, mottled brown and speckled greyish-white; central crown broadly streaked blackish-brown, no nuchal collar; lesser coverts chestnut to greyish, speckled brown, rest of wing-coverts greyish-brown boldly spotted buff; scapulars blackish-brown, edged and tipped buff, tawny or chestnut, especially on inner webs; buffish eye-ring and submoustachial stripe, rufous or chestnut lores and ear-coverts, and white throat patch, occasionally restricted to small white spot on either

side of lower throat; underparts greyish-brown tinged rufous, speckled and vermiculated brown, becoming buff barred brown on belly and flanks. Male has broad white band across outermost primaries, with outermost tail feather dark, next two outermost feathers largely white; female has thinner white wing-bands washed buff or tawny, and narrow white tips to second and third outermost tail feathers. Iris dark brown, bill blackish, legs and feet greyish. A less common rufous morph exists, with overall coloration tinged rufous cinnamon. Immature similar to adult, but male has thinner white wing-bands and female has tawny bands. Racial variation involves size, coloration and (in males of some subspecies) extent of white in tail. **Voice.** Song of male is a variable, whistled "wheow", "who", often preceded by soft "ko", "put" or "puk" calls, from ground or perches. Calls include rapid whips, clucks and soft whups; guttural hissing sounds, rattles and grunts are given during distraction displays; adult uses croaks and clucks when calling to offspring, chick utters soft peeps.

Habitat. Mainly forested or wooded country: forest edges and clearings, open woodland, riparian woodland, second growth and plantations. Also scrubland, open country with thickets, cultivated land, semi-arid regions, xerophytic areas, llanos, marshland and mangroves. Recorded at all altitudes from sea-level to 2300 m, occasionally to 3000 m.

Food and Feeding. Diet includes beetles, moths, butterflies, bugs, bees, wasps, antlions, ants and Orthoptera. Forages by making short sallies from ground, or by flycatching from low perches. Also hunts over open country, clearings, pastures and fields, often hawking for prey close to ground.

Breeding. Breeds Feb-Jul in Texas, late Mar to late Jun in Mexico, Feb-May in Nicaragua and Costa Rica, late Feb to Jun in Panama, Jan-May (occasionally to Aug) in Colombia, Mar-Jun in Ecuador and Venezuela, Feb-Jul in Trinidad, Mar-Oct in Surinam (though eggs found in every month except Feb), up to late Aug in French Guiana, Sept (perhaps) to Jan in SE Brazil, and Oct-Nov in Paraguay; no data from other regions but possibly Jul-Jan in S latitudes. Nest-site at base of bush or small tree, in small opening or clearing in thickets or low vegetation, in clearing or along roadside in forest, among scattered vegetation in open or semi-open country, in pasture or field, along edge of cultivated land, or among stones and boulders on dry floodplain of river or stream; no nest, eggs laid on leaf litter, bare or stony ground or pebbly sand. Clutch 1-2 eggs, elliptical, elliptical-ovate or ovate, slightly glossy, pale salmon-pink tinged ochraceous, or pinkish-buff, blotched and spotted brown, buff and lilac, markings concentrated around blunt end, or sometimes almost unmarked; incubation often by male during day, period 19-20 days; adults threatened at nest-site perform injury-feigning distraction display; chick semi-precocial, covered in brown and pinkish-buff downy.

Movements. Most populations appear to be largely sedentary. Race *merrilli* partially migratory, northern birds apparently moving S after breeding, and possibly wintering in E Mexico.

Status and Conservation. Not globally threatened. Data from many regions surprisingly scarce, but considered fairly common to abundant throughout much of range, generally occurring in a variety of habitats in tropical lowlands. Fairly common throughout much of W, E & S Mexico; abundant in many regions in Guatemala, though slightly less common in Pacific lowlands; common throughout Costa Rica; common in suitable habitat throughout Panama, though only locally so on Caribbean side and much scarcer in forests and densely wooded country. Commonest and most widespread nightjar in Colombia; very common in Venezuela; fairly common in suitable habitat in Trinidad; widespread and common throughout Guyana; common throughout Surinam; in Brazil, common in Mato Grosso, fairly common to common in Atlantic forest region, frequent in Rio de Janeiro but scarce in Rio Grande do Sul. Eggs and young may be vulnerable to trampling by domestic cattle, ground fires and, if near streams and rivers, flooding by high water. Potential predators include various species of birds, mammals and reptiles; chicks may also fall victim to fire ants.

Genus *PHALAELOPTILUS* Ridgway, 1880

19. Common Poorwill

Phalaenoptilus nuttallii

French: Engoulevent de Nuttall **German:** Winternachtschwalbe **Spanish:** Chotacabras Pachagua
Other common names: Poorwill

Taxonomy. *Caprimulgus Nuttallii* Audubon, 1844, upper Missouri between Fort Pierre and mouth of the Cheyenne River, South Dakota.

Five subspecies currently recognized.

Subspecies and Distribution.

P. n. nuttallii (Audubon, 1844) - SW Canada S through W USA to N Mexico.
P. n. californicus Ridgway, 1887 - W California and NW Baja California.
P. n. hueyi Dickey, 1928 - SE California, SW Arizona and N Baja California.
P. n. dickeyi Grinnell, 1928 - S Baja California.
P. n. adustus van Rossem, 1941 - extreme S Arizona S to C Sonora.

Descriptive notes. 18-21 cm; male 31-58 g, female 37-58 g. Sexually dimorphic, though only marginally so. Upperparts greyish-brown or greyish-white, speckled and barred brown, boldly spotted blackish-brown on crown, no nuchal collar; wing-coverts pale greyish-brown, streaked and barred blackish-brown, tipped buffish; scapulars pale greyish-buff or greyish-white with broad, almost star-shaped, blackish-brown centres; no supercilium but sides of crown often thinly edged white; blackish mask; thin, white (male) or buffish (female) submoustachial stripe; chin and throat dark brown and sides of lower throat whitish; rest

of underparts generally pale greyish-brown or buffish, barred brown. Both sexes lack white markings on wings but have all but central pair of tail feathers narrowly tipped white, more boldly so in male. Iris dark brown, bill blackish, legs and feet brownish. Immature similar to adult; juvenile dull buffish-white speckled greyish, lacking blackish-brown spotting on crown, with buffish (not white) patches on sides of lower throat and less distinct blackish-brown markings than adult, especially on underparts. Races vary slightly in size and overall coloration. **Voice.** Song of male is a melodious, whistled "poor-will-low" given from ground or perches; calls include high-pitched squeaks and, when alarmed, clucking "werk" or "quirk" sounds; guttural hissing or growling during threat and defence displays; chick utters cheeps or peeps.

Habitat. Typically arid or semi-arid country: deserts, gravelly plains, open prairie, grassy hillsides, rocky terrain with scattered vegetation or dry brush, rocky canyons and chaparral. Also open woodland, and clearings in pine or fir forest. Generally between 500 m and 1000 m, occasionally to 2500 m or higher.

Food and Feeding. Diet consists mainly of beetles, moths, cicadas, bugs, grasshoppers, locusts, flying ants and flies. Forages by making short sallies from ground or perches; also forages in flight by hawking after prey, takes insects from surfaces by fluttering close to vegetation, and occasionally takes food from ground. Also feeds on insects attracted to artificial lights.

Breeding. Probably breeds late May to Sept in N of range, Mar-Aug in S. Occasionally double-brooded, second clutch often laid within 100 m of first site. Monogamous and territorial. Nest-site usually beneath overhanging foliage or in log-strewn clearing, may be partially shaded by logs or rocks or in full sunlight; no nest, eggs laid on pine needles, bare ground, rotten log, gravel or flat rock. Clutch 2 eggs, elliptical or oval, smooth and slightly glossy, creamy-white with faint pink tinge, unmarked or faintly spotted around blunt end, laid on consecutive days; replacement clutch often laid if first lost; incubation begins with first egg, shared by both sexes, but more often by male during day, period 20-21 days; adults threatened at nest-site perform defence or distraction display; eggs hatch asynchronously, chick semi-precocial, covered in pale buff or greyish-buff down, often tinged vinaceous, fed by regurgitation; fledging at 20-23 days of age.

Movements. Well known for habit of hibernation during cold weather (see page 309). Nominate race in part sedentary and in part migratory. N populations leave breeding grounds late Sept to Nov (N birds departing earlier than S) and move S to winter throughout S parts of range from SE California and S Texas to C Mexico; S limit of wintering range poorly known. Return to breeding grounds Feb-Mar (late Apr to mid-May farther N). Race *californicus* also migratory in N of range and sedentary in S. Other races generally sedentary, although some populations of race *adustus* may undertake altitudinal movements outside breeding season. Possible vagrant recorded in Florida.

Status and Conservation. Not globally threatened. In USA, not officially listed, e.g. by US Fish and Wildlife Service, as threatened or endangered anywhere in range; in Canada, not listed by Committee on the Status of Endangered Wildlife in Canada, but red-listed by British Columbia Ministry of the Environment. In North America, uncommon in N and E of range, locally common in SW (California, Arizona, New Mexico and Colorado), local and sparsely distributed on Great Plains where slight expansion of breeding range in NE with recent records from SW North Dakota and SE Saskatchewan. Fairly common in N & C Mexico, becoming more frequent in winter after

arrival of migrants from farther N. Data from Breeding Bird Survey (1966-1991) suggest US population increasing, especially so in W of range and in Texas, but within this same period the more recent data (1982-1991) suggest possible decrease in numbers in Canada and USA; territories occasionally 0.5 km apart. Forest fires, light logging or cattle grazing may improve breeding habitats locally. Eggs and young probably taken by predators such as birds of prey, crows (*Corvus*), coyotes (*Canis latrans*), foxes (*Canidae*), badgers (*Taxidea taxus*), skunks (*Mustelidae*) and snakes. Adults may be taken by birds of prey such as Hen Harrier (*Circus cyaneus*) or Great Horned Owl (*Bubo virginianus*).

Genus *SIPHONORHIS* P. L. Sclater, 1861

20. Jamaican Poorwill

Siphonorhis americana

French: Engoulevent de la Jamaïque Spanish: Chotacabras Jamaicano
German: Jamaikanachtschwalbe
Other common names: Jamaican Pauraque, Least Poorwill(!)

Taxonomy. *Caprimulgus americanus* Linnaeus, 1758, Jamaica. Formerly considered conspecific with *S. brewsteri*, and these two form a superspecies. Monotypic.
Distribution. Jamaica.

Descriptive notes. 23-25 cm. Sexually dimorphic, though only marginally so. Upperparts rufous-brown streaked blackish-brown, crown broadly streaked blackish, indistinct buffish nuchal collar; wing-coverts rufous-brown, distinctly marked blackish-brown, with small, brown-centred, pale buff spots; large white throat patch; underparts rufous-brown, boldly spotted whitish on upper belly, becoming buff barred brown towards tail. Both sexes lack white markings on wings; male has all but central pair of tail feathers narrowly tipped white, female has yellowish-buff tips. Immature plumages unknown. Voice. Unknown.

Habitat. Exact requirements unknown, but possibly dry limestone forest, semi-arid woodland or open country.

Food and Feeding. Diet probably insects. Foraging methods unknown.

Breeding. No information.

Movements. None recorded.

Status and Conservation. CRITICALLY ENDANGERED. Restricted-range species: present in Jamaica EBA. Possibly never really common and known only from four museum specimens: a male taken in or about 1844, a male taken at Savanna la Mar in Bluefields area of Westmorland in Aug 1858, a female taken at Freeman's Hall, near Albert Town in Trelawney, in Sept 1859, and a male taken near Linstead, St Thomas-in-the-Vale (Worthy Park area of St Catherine, perhaps near Spanish Town), possibly in Nov 1860. Apart from these four old museum specimens, not recorded again with certainty and often considered now extinct, although possible recent sightings have been reported from Milk R and Hellshire Hills. It has often been speculated that deforestation, and also introduction of mongooses (*Herpestes auropunctatus*) in 1872 and rats (*Rattus*), which might have preyed upon eggs and chicks, may have contributed to the disappearance of this species.

Bibliography. Anon. (1998a), Bond (1985), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Fuller (1987), Greenway (1967), Knox & Walters (1994), Raffaele *et al.* (1998), Sclater (1861), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Sutton (1981).

21. Least Poorwill

Siphonorhis brewsteri

French: Engoulevent grouillécro German: Haitinachtschwalbe Spanish: Chotacabras Torico
Other common names: Least Pauraque

Taxonomy. *Microsiphonorhis brewsteri* Chapman, 1917, Túbano, Azua, Dominican Republic. Formerly considered conspecific with *S. americana*, and these two form a superspecies. Monotypic.
Distribution. Hispaniola, including Gonáve I.

Descriptive notes. 17-21.5 cm. Sexes believed similar. Upperparts greyish-brown streaked blackish-brown, crown broadly streaked blackish, broad buff nuchal collar; wing-coverts greyish-brown, boldly spotted white; underparts dark brown, boldly spotted white on breast and becoming white, barred and vermiculated brown on belly; both sexes lack white markings on wings; male has all but central pair of tail feathers narrowly tipped white, female possibly similar or may have tips pale buff. Juvenile similar to adult, but upperparts distinctly spotted blackish-brown, and belly and flanks pale buff faintly barred brown. Voice. Song of male is a whistled "toorrrri" rising in pitch,

or a warbled "toorrrri"; calls include short, whistled "toorric" or "to-ic" and dove-like scratchy sounds.

Habitat. Typically arid or semi-arid lowlands, especially scrubby limestone woodland and areas with cactus and thorn scrub; also occurs in deciduous, coniferous or mixed forest. Recorded from sea-level to 800 m.

Food and Feeding. Diet probably consists of insects. Foraging methods not recorded.

Breeding. Poorly documented. Possibly breeds Apr-Jun. One nest-site was on top of a narrow ridge at edge of burnt land; no nest, eggs laid on ground. Eggs elliptical, dull white, spotted

pale purplish-grey, and spotted and scrawled buff and pale brown; adults threatened at nest-site may perform distraction display.

Movements. None recorded. Sedentary.

Status and Conservation. Not globally threatened. Restricted-range species: present in Hispaniola EBA. Currently considered Near-threatened. Rare, but possibly under-recorded. In late 1920's considered local in Haiti and fairly common on Gonáve I, though may have suffered from habitat loss, with large areas of scrubland often burnt off by local people, thereby restricting birds to reduced areas of native woodland; destruction of suitable habitat considered almost complete by 1970's. Apparently not reported at all between 1928 and 1969, probably owing to little or no observer coverage. In early 1970's located at 16 widespread localities in W & C Dominican Republic where previously unnoticed either because of lack of observers or as a result of a range expansion from Haiti, where habitat diminishing; several recent records from Lago Enriquillo area in centre of the island (Dominican Republic). Potential threats include predation by introduced mongooses (*Herpestes auropunctatus*) and rats (*Rattus rattus* and *R. norvegicus*) and loss of habitat through slash and burn clearance for agriculture, or taking of timber for charcoal burning.

Bibliography. Anon. (1998a), Bond (1928a, 1928b, 1985), Dod (1979, 1987, 1992), Greenway (1967), Raffaele *et al.* (1998), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Wetmore & Swales (1931).

Genus *NYCTIPHRYNUS* Bonaparte, 1857

22. Eared Poorwill

Nyctiphrynus mcleodii

French: Engoulevent aztèque German: Ohrennachtschwalbe Spanish: Chotacabras Prió

Taxonomy. *Otophanes mcleodii* Brewster, 1888, Chihuahua, Mexico. Sometimes placed in genus *Otophanes*, usually along with *N. yucatanicus*. Two subspecies recognized.

Subspecies and Distribution.

N. m. mcleodii (Brewster, 1888) - NW Mexico (Chihuahua and S Sonora to Jalisco and Colima).
N. m. rayi A. H. Miller, 1948 - CW Mexico (Guerrero).

Descriptive notes. 20-21 cm; male 31-37 g, female 24-35 g. Sexes similar. Upperparts greyish, wing-coverts spotted white, scapulars boldly spotted blackish, narrow buffish-white nuchal collar; conspicuous white band around throat; underparts greyish becoming buff lightly spotted white on belly. Both sexes lack white markings on wings, but have all but central pair of tail feathers narrowly tipped white. Iris dark brown, bill dusky or flesh with black tip, legs and feet pale pinkish-brown or greyish. A rufous morph exists, mainly in female, with general coloration rufous cinnamon to rufescent-brown. Race *rayi* darker and greyer,

with smaller white spots on wing-coverts. Voice. Song of male is a loud, abrupt "peeeyo" or "peejo"; also gives a descending, wavering "teu-uu-uu". Sings from ground or perches throughout night. Calls include short "gwik" or "wuik"; both sexes utter soft "chuk" notes; if disturbed, female may give a short, trilled churr.

Habitat. Mainly open woodland of pine and/or oak, usually in semi-arid, mountainous terrain; also woodland edge, wooded gulleys, oak-covered hillsides below cloudforest, and occasionally overgrown fields with scattered trees. Recorded from 600-2500 m.

Food and Feeding. Feeds on insects, especially beetles and moths. Forages by making short flycatching sallies from trees or ground.

Breeding. Poorly documented. Possibly breeds Apr-Jun. Nest-sites recorded in short grass at cliff base and in clumps of pines (*Pinus teocote*); no nest, eggs laid on ground or pine needles. Clutch 2 eggs, ivory-white, unmarked.

Movements. Mainly sedentary, although occasionally may undertake local movements as race *rayi* reported as a casual visitor to state of Oaxaca.

Status and Conservation. Not globally threatened. Currently considered Near-threatened. A little-known species endemic to W Mexico, where locally rare to fairly common in suitable habitat. Widely distributed in SW Jalisco and neighbouring Colima, possibly not uncommon in C Sierra Madre del Sur, Guerrero. No data available from other regions.

Bibliography. Anon. (1998a), Arnold (1971), Binford (1989), Hernández-Baños *et al.* (1995), Howell & Webb (1994, 1995a), Miller (1948), Ridgway (1912b), Schaldach (1963), Schaldach & Phillips (1961), Stotz *et al.* (1996).

23. Yucatan Poorwill

Nyctiphrynus yucatanicus

French: Engoulevent du Yucatan Spanish: Chotacabras Yucateco
German: Yucatannachtschwalbe

Taxonomy. *Caprimulgus yucatanicus* Hartert, 1892. Tizimin, Yucatán, Mexico. Sometimes placed in genus *Otophanes* along with *N. mcleodii*, or in monotypic *Nyctagreuus*. Monotypic.

Distribution. Yucatán Peninsula of Mexico, N Guatemala and N Belize.

Descriptive notes. 19.5–22 cm; 1 male 21 g. Sexes similar. Upperparts brown streaked blackish-brown, lightly spotted buffish-white on wing-coverts; narrow and indistinct buffish nuchal collar and large white throat patch; underparts brown narrowly streaked blackish-brown on breast, becoming brown or brownish-buff spotted white on belly. Both sexes lack white markings on wings, but have all but central pair of tail feathers narrowly tipped white. Iris dark brown, bill blackish, legs and feet brown. A rufous morph exists, apparently mostly in female, with overall coloration pinkish-cinnamon. Immature plumages unknown.

Voice. Song of male is a repetitive “weeo, weeo, weeo” given from perches. Other calls include liquid clucking sounds and “week, week” notes.

Habitat. Typically scrubland, deciduous forest and open woodland, usually in arid or semi-arid lowlands; also farmland and fields, second growth and thorny woodland. Recorded from sea-level to 250 m.

Food and Feeding. Probably feeds on insects. Forages by making short sallies from trees or ground.

Breeding. Poorly documented. Breeds Apr–Jun in Guatemala; no data from other regions. No nest, eggs laid on leaf litter on ground. Eggs elliptical, glossy, buffish, speckled brown; adults threatened at nest-site perform injury-feigning distraction display on ground.

Movements. None documented. Possibly sedentary.

Status and Conservation. Not globally threatened. Endemic to Yucatán Peninsula of Mexico, with range extending S into Belize and N Guatemala. During 1940’s and 1950’s considered fairly abundant in lowland deciduous forests, less frequent in areas of second growth within rainforest zone. First recorded S of San Ignacio, Belize, in Feb 1990, furthest S locality for this species. Probably remains fairly common throughout range, though few data available.

Bibliography. Anon. (1998a), Hardy & Straneck (1989), Howell & Webb (1995a), Howell *et al.* (1992), Land (1970), Paynter (1955), Pierson (1986), Ridgway (1912b), Russell (1964), Smithe (1966), Stotz *et al.* (1996), Vallely & Whitman (1997), Van Tyne (1935).

24. Ocellated Poorwill

Nyctiphrynus ocellatus

French: Engoulevent ocellé **German:** Augennachtschwalbe **Spanish:** Chotacabras Ocelado

Taxonomy. *Caprimulgus ocellatus* Tschudi, 1844, Peru.

Until recently considered conspecific with *N. rosenbergi*, but differs vocally and may not even be closely related. Two subspecies currently recognized.

Subspecies and Distribution.

N. o. lautus W. deW. Miller & Griscom, 1925 - NE Nicaragua, NW Costa Rica and possibly Panama (Canal Zone); recently discovered breeding in extreme E Honduras.

N. o. ocellatus (Tschudi, 1844) - CS Colombia, NE Ecuador and E Peru to E Brazil and S through Bolivia and Paraguay to NE Argentina and extreme S Brazil.

Descriptive notes. 20–21 cm; male 35–43 g, female 29–44 g. Sexes similar. Upperparts and wing-coverts almost uniformly dark greyish-brown, no nuchal collar; scapulars and some wing-coverts boldly spotted blackish-brown, spots bordered rufous or buffish; white band around throat; underparts dark greyish-brown, spotted white on belly. Both sexes lack white markings on wings, but have all but central pair or two pairs of tail feathers narrowly tipped white. Iris dark brown, bill blackish, legs and feet dark brown. A rufous morph exists, paler and more reddish-brown overall. Immature plumages unknown. Race *lautus* smaller with

narrower white tips to outer tail feathers. **Voice.** Song of male is a repetitive trilled “preeo” given from perches or ground, mainly at dusk. Call is a soft, guttural “wah, wah, wah”.

Habitat. Prefers lowland forest with open understorey and small, shady clearings; also occurs in dense second-growth forest with plenty of small trees and vines. Reported from sea-level to 1350 m.

Food and Feeding. Feeds on moths, beetles, cockroaches (including Blattidae), katydids (including Tertrigoniidae) and fireflies (including Lampyridae). Forages by making short sallies from low perches.

Breeding. Poorly documented. Possibly breeds Mar–Apr in Costa Rica and Nicaragua, and Oct–Nov in Peru; a female incubating 2 eggs in May in Honduras; no data from other regions. Nest-site often below overhanging foliage; no nest, eggs laid on leaf litter. Clutch 2 eggs, elliptical, off-white to pinkish-white, unmarked or faintly spotted reddish.

Movements. None recorded. Sedentary.

Status and Conservation. Not globally threatened. As a forest inhabitant with nocturnal habits, difficult to find, e.g. not recorded in Bolivia until 1940’s, possibly because of under-recording rather than range expansion. Recently discovered (1997) breeding in E Honduras, at Las Marias in Río Plátano Biosphere Reserve, situated in region of over 250,000 ha of relatively undisturbed lowland rainforest, with small human population. Small breeding population in NW Caribbean lowlands of Costa Rica may be result of a range expansion from Nicaragua, where first discovered in 1909. As yet, not reliably recorded in Panama, though a sight report from Canal region, Mar 1978. Local in Colombia, probably occurring in forests on E slope of E Andes. In Peru, occurs in Manu National Park and Tambopata Reserve. Fairly common in Augusto Ruschi Biological Reserve, Atlantic forest region, Brazil; also found in Sooretama Biological Reserve, Espírito Santo. Rare in E Paraguay. Loss of habitat due to deforestation probably potential threat in some regions, especially to Central American population.

25. Choco Poorwill

Nyctiphrynus rosenbergi

French: Engoulevent du Choco

Spanish: Chotacabras del Chocó

German: Rosenberg-Nachtschwalbe

Taxonomy. *Caprimulgus rosenbergi* Hartert, 1895, Río Dagua, Colombia.

Formerly considered conspecific with *N. ocellatus*, but differs vocally and may not even be closely related. Monotypic.

Distribution. Chocó region of W Colombia and NW Ecuador.

Descriptive notes. 19.5–21 cm; 1 female 52 g. Sexes similar. Upperparts and wing-coverts darkish brown, washed cinnamon and rather heavily spotted blackish-brown, with two or three large white spots on inner greater coverts; no nuchal collar; large white throat patch; underparts darkish brown, washed cinnamon on breast, greyish-white on belly. Both sexes lack white markings on wings but have all tail feathers narrowly tipped white. Iris dark brown, bill blackish or grey with black tip, legs and feet greyish or purplish-brown. Immature similar to adult but markings on upperparts and breast more chestnut, and lacks white spots on

inner greater coverts; little colour variation noted, although male can be rather blackish. **Voice.** Song of male is a short, resonant “kwor, kwor, kwecé”, final note being whistled. Sings mainly at dusk and dawn. Calls include “whee, whurrr” or “kwee, whurrr” notes, first note rising in pitch, second trilled and descending.

Habitat. Mainly primary forest but also adjacent secondary forest, from sea-level to 900 m.

Food and Feeding. Feeds mainly on moths and beetles (including Scarabaeidae and Curculionidae). Forages by hawking for insects above forest canopies and in clearings.

Breeding. Almost entirely unknown. Breeds Mar–Jun in Ecuador (chicks found mid-Apr) and May–Jun in Colombia (chicks found early Jun).

Movements. None recorded. Sedentary.

Status and Conservation. Not globally threatened. Restricted-range species: present in Chocó EBA. Currently considered Near-threatened. In SW Colombia, possibly locally widespread in suitable habitat W of Andes; fairly common within primary forest at Alto Tambo, NW Ecuador, where habitat remains largely intact and species possibly not under immediate threat. No data from other localities.

26. Chuck-will's-widow

Caprimulgus carolinensis

French: Engoulevent de Caroline **Spanish:** Chotacabras de la Carolina

German: Carolinanachtschwalbe

Other common names: Carolina Chuck-will

Taxonomy. *Caprimulgus carolinensis* J. F. Gmelin, 1789, South Carolina. May form superspecies with *C. rufus*, with which has even been considered conspecific, but differs notably in both voice and morphology. Monotypic.

Distribution. E North America S from Kansas, extreme S Ontario and Massachusetts. Winters from S USA (SE Texas and Louisiana) S through Central America to N South America; and from N Florida S through Bahamas to Greater Antilles, and E to Virgin Is.

Descriptive notes. 27-34 cm; male 94-137 g, female 114-118 g. Sexually dimorphic. Upperparts brown, broadly streaked blackish-brown, with narrow and indistinct tawny-buff nuchal collar; wing-coverts brown, heavily spotted buff and buffish-white; scapulars boldly spotted blackish; narrow white or buffish-white band around lower throat; underparts brown, speckled and spotted tawny and buff, becoming buff barred brown on belly; both sexes lack white markings on wings. Male has white inner webs to three outermost tail feathers, outer webs being tawny, speckled or barred blackish; female lacks white on tail. Iris dark brown, bill

dusky flesh with black tip, legs and feet dull flesh. Generally larger than *C. rufus*; larger and less variegated than *C. vociferus*. Immature similar to adult female. **Voice.** Song of male is a loud, repetitive "chuk, weeo, weeo"; song variable and may be faster, higher pitched, or more muted. Sings from perches, mainly at dusk, dawn and throughout moonlit nights, and occasionally during daytime; sings less strongly while breeding. Flight calls, given by both sexes, include clucks, growls and deep "quok" notes; guttural hissing sounds are uttered during threat/defence displays.

Habitat. Generally deciduous wood and forest, mixed woodland of pines and oaks, and wooded oak groves; also suburban habitats, open country, pastureland and coniferous forest. Outside breeding season, also in thick woodland, open woodland, scrub and palmetto thickets, tangled riverside vegetation, mature hedgerows and second-growth woodland. Reported from sea-level to 2600 m. **Food and Feeding.** Feeds on moths, flying ants, cicadas, crickets, grasshoppers, damselflies, dragonflies, beetles (including Carabidae, Cerambycidae, Elateridae and Scarabaeidae), bugs, flies and small birds (including Emberizidae, Trochilidae and Hirundinidae). Also known to take bivalves. Hunts in flight along woodland edges and over open areas, often flying low over ground, and also forages by making short flycatching sallies from perches. Birds in heavy moult may feed on ground by scuttling about after prey.

Breeding. Breeds mid-Apr to Jul, commencing early Mar in S of range, mid-May in N. Usually single-brooded. Territorial. Nest-site usually in open situation, may be used for several years; no nest, eggs laid on leaf litter or pine needles, on ground. Clutch 2 eggs, oval or elliptical, glossy, cream, pinkish-cream or white, blotched, marbled and spotted with brown, tawny, lilac, grey and purple, laid on consecutive days; replacement clutches sometimes laid if first lost; incubation usually by female during day, period generally c. 20 days; female threatened at nest-site may give distraction display from perch or on ground; eggs hatch asynchronously; chick semi-precocial, covered in golden-brown or yellowish-ochre down, fledge at c. 16 days but may remain dependent on adults for another 14 days.

Movements. Migratory, males generally moving before females. Begins arriving in N parts of range by mid-late Mar. Occasionally found N of normal breeding range, and perhaps also occurs N Bahamas. Post-breeding migration begins early Sept. Winters from S USA through Central America and West Indies to N South America. Vagrants recorded on St Martin, St Barthélemy and Barbuda. Adults tend to winter in Greater Antilles, immatures in Central & South America.

Status and Conservation. Not globally threatened. Generally common throughout North American breeding range, and apparently spreading N in some regions, with increases noted in Massachusetts and New York; common in winter in S parts of range, e.g. frequent in S half of Florida Peninsula. Common spring and autumn passage migrant through E Mexico; frequent winter visitor from SE Mexico to Honduras, though probably not common in Guatemala; common (Sept-May) in Hispaniola, uncommon (Sept-May) in Bahamas, Cuba and Jamaica and on Saba, rare (Sept-May) in Puerto Rico, Virgin Is and Cayman Is; widespread but uncommon passage migrant and winter visitor (Oct-Apr) in Costa Rica and Panama; perhaps rare winter visitor (late Nov to mid-Feb) in Colombia; casual winter visitor in Venezuela. On breeding grounds, predators of eggs include striped skunk (*Mephitis mephitis*).

27. Rufous Nightjar

Caprimulgus rufus

French: Engoulevent roux **German:** Rostnachtschwalbe **Spanish:** Chotacabras Colorado

Other common names: Ruddy Nightjar (*minimus*); St Lucia/St Lucien Nightjar (*otiosus*)

Taxonomy. *Caprimulgus rufus* Boddaert, 1783, Cayenne.

May form superspecies with *C. carolinensis*, with which has even been considered conspecific, but differs notably in both voice and morphology. Race *otiosus* has been considered a distinct species, on the basis of supposed sympatric breeding in N Venezuela; however, presence of this race in Venezuela now seems rather unlikely, as the relevant specimens were in poor condition and anyway do not appear to have matched *otiosus* well; also, differences from other races in vocalizations and plumage are minimal and do not appear to justify this split. Race *minimus* has also been considered a separate species, but again differences appear insufficient. Race *saltarius* initially thought to belong to *C. sericocaudatus*; subsequently found to be closer to present species, but thought to occur sympatrically with *rufus* and so raised to full species status; however, voice and morphometrics convincingly show it to belong within present species, where it is sometimes synonymized with *rufus*, being considered merely a grey plumage morph. Race *rufus* includes proposed forms *ornatus* and *cortapau*; nominate *rufus* includes proposed race *noctivigularis*. Recent sight records of present species from C Colombia, S Ecuador, Peru and C Brazil not yet subspecifically assigned; some of these may refer to as yet undescribed races. Five subspecies currently recognized.

Subspecies and Distribution.

C. r. minimus Griscom & Greenway, 1937 - S Costa Rica to N Colombia, N Venezuela and NW Trinidad (including Bocas Is).

C. r. otiosus (Bangs, 1911) - NE St Lucia in Lesser Antilles.

C. r. rufus Boddaert, 1783 - S Venezuela E through the Guianas and NE Brazil.

C. r. rufus (Burmeister, 1856) - S Brazil, E Bolivia, Paraguay and NE Argentina.

C. r. saltarius Olog, 1979 - NW Argentina and possibly SE Bolivia.

Populations in C Colombia, S Ecuador, Peru and C Brazil of uncertain status and not yet assigned to race.

Descriptive notes. 25-30 cm; 1 male 88 g, female 89-98 g, 1 unsexed 95 g. Sexually dimorphic. Upperparts rufescent-brown, broadly streaked blackish-brown, with narrow and indistinct tawny-buff nuchal collar; lesser coverts dark brown, speckled rufous or tawny, rest of wing-coverts rufescent-brown, speckled rufous and buff and boldly spotted blackish-brown; scapulars boldly spotted blackish-brown; narrow white or buffish-white band around lower throat; underparts rufescent-brown, barred brown, speckled and spotted cinnamon, buff and white, becoming buff barred brown on undertail-coverts; both sexes lack white markings on

wings. Male has large white spot on inner webs of three outermost tail feathers, outer webs being tawny with black bars; female lacks white markings on tail. Iris dark brown, bill dusky with blackish tip, legs and feet brownish-flesh. Generally smaller and darker than *C. carolinensis*. Juvenile paler than adult, with crown, scapulars and some wing-coverts pale buff or whitish, distinctly spotted black. Racial variation includes overall coloration, size and colour of nuchal collar, and in males size of white tail spots. **Voice.** Nocturnal song of male is a loud "chuk, wee, wee, weeo" given from branches or rocks or sometimes from ground. Call is a guttural croak.

Habitat. Generally forest: rainforest, gallery forest, second-growth forest, open woodland and forest edge; also scrubland and savanna thickets and large suburban gardens. In Trinidad, typically in scrubland and deciduous woodland, and on St Lucia prefers arid brush country. Generally recorded from sea-level to 1000 m, but up to 1800 m in Colombia.

Food and Feeding. Feeds on insects. Forages by hawking or flycatching from low perches, often in forest interiors.

Breeding. Poorly known. Possibly breeds Jan-May in Panama, Jun on St Lucia, Feb-May in Trinidad, mid-Apr to May in Colombia, and Oct-Dec in N Argentina; no other published data available. Nest-site usually beneath vegetation or beside log; no nest, eggs laid on bare ground or leaf litter. Clutch 1-2 eggs, elliptical, creamy-white, blotched light brown and dull lilac; incubation usually by female during day; chick not described.

Movements. Poorly known; most populations may be sedentary. Race *rufus* partially migratory. S populations moving N after breeding season, possibly wintering (May-Aug) as far away as Venezuela. Race *saltarius* possibly also partially migratory.

Status and Conservation. Not globally threatened. Rare and local in S Costa Rica; locally fairly common on Pacific side of Panama, scarcer and more local on Caribbean side, occurring in Canal area only. Widely distributed and uncommon to fairly common throughout much of South America, where apparently not immediately endangered; fairly common in NW peninsula of Trinidad and on Bocas Is; widespread and not uncommon in some parts of St Lucia, especially in NE coastal areas; uncommon and infrequently recorded in Colombia; locally distributed in Venezuela, but present in Henri Pittier National Park; rare but possibly overlooked in Surinam; locally very common in Amazonian Brazil, common Apr-Oct in Mato Grosso but scarce in Rio Grande do Sul; fairly widespread in SW Bolivia; rare to uncommon in E Paraguay, and very common in NW Argentina. Loss of habitat through deforestation a potential threat in some regions, and on St Lucia eggs, chicks and possibly adults may be preyed by introduced mongooses (*Herpestes auripunctatus*) and rats (*Rattus*).

Bibliography. Babbs *et al.* (1988), Belton (1984), Canevari *et al.* (1991), Chebez (1994), Contreras *et al.* (1990), Dubs (1992), French (1991), Greenway (1967), Haverschmidt & Mees (1994), Hayes (1995), Hilty & Brown (1986), Keith (1997), Kiff (1975), Meyer de Schauensee & Phelps (1978), Nores & Yzurieta (1984), Olog (1979a), Oren & Parker (1997), de la Peña (1994), Raffaele *et al.* (1998), Ridgely & Gwynne (1989), Robbins & Parker (1997), do Rosário (1996), Schubart *et al.* (1965), Short (1975), Sick (1993, 1997), Slud (1964), Snyder (1966), Stiles & Skutch (1989), Stotz *et al.* (1996), Tostain *et al.* (1992), Wetmore (1968a), Wetmore & Phelps (1953).

28. Cuban Nightjar

Caprimulgus cubanensis

French: Engoulevent peut-on-voir **German:** Kubanachtschwalbe **Spanish:** Chotacabras Cubano

Other common names: (Greater) Antillean Nightjar (with *C. ekmani*)

Taxonomy. *Antrostomus Cubanensis* Lawrence, 1860. Ciénaga de Zapata and coast of Manzanillo, Cuba.

May form superspecies with *C. ekmani*, with which it was until recently considered conspecific, but notable differences in voice. Two subspecies recognized.

On following pages: 29. Hispaniolan Nightjar (*Caprimulgus ekmani*); 30. Tawny-collared Nightjar (*Caprimulgus salvini*); 31. Yucatan Nightjar (*Caprimulgus badius*); 32. Silky-tailed Nightjar (*Caprimulgus sericocaudatus*); 33. Buff-collared Nightjar (*Caprimulgus ridgwayi*); 34. Whip-poor-will (*Caprimulgus vociferus*); 35. Puerto Rican Nightjar (*Caprimulgus noctitherus*); 36. Dusky Nightjar (*Caprimulgus saturatus*).

Subspecies and Distribution.

C. c. cubanensis (Lawrence, 1860) - Cuba.

C. c. insulaepinorum Garrido, 1983 - I of Pines and Cayo Coco.

outermost tail feathers; female has narrow buff tips. Iris brown, bill blackish, legs and feet brownish. Differs from *C. ekmani* by less streaking on crown; also by broad pale buff throat band, and narrower white (male) or buff (female) tips to three outermost tail feathers. Immature plumages not described. Racial variation apparently clinal, with *insulaepinorum* smaller and darker. Voice. Song of male is a short, evenly pitched, trilled whistle, "terrrrrrrr"; a 4-syllable phrase, "gua bai ah ro". **Habitat.** Typically open woodland, but also favours edges of swampland and rivers. On Isle of Pines, also dense woodland and scrubland.

Food and Feeding. Feeds on insects. Foraging methods not described.

Breeding. Poorly documented. Breeds Mar-Jul. Nest-site in dense scrub or thicket at edge of clearing; no nest, eggs laid on leaf litter on ground. Clutch 1-2 eggs, elliptical, dull white often tinged pinkish-buff, marked and spotted brown, brownish-buff and greyish-purple; both sexes incubate; adults threatened at nest-site may perform distraction display; chick not described.

Movements. None recorded. Sedentary.

Status and Conservation. Not globally threatened. Poorly known, with few data available. Occurs throughout Cuba, where possibly locally common. On Isle of Pines, first reported in dense woodland S of Ciénaga de Lanier in 1905 and still apparently commoner in that region and the S than elsewhere on the island. Potential threats to breeding birds include the introduced small mongoose (*Herpestes auro-punctatus*).

Bibliography. Alayón (1985), Anon. (1998a), Balát & González (1982), Barbour (1943), Bond (1934, 1985), García (1985), Garrido (1983), Garrido & Reynard (1994, 1998), Gundlach (1873), Raffaele *et al.* (1998), Stotz *et al.* (1996), Vaurie (1957).

29. Hispaniolan Nightjar

Caprimulgus ekmani

French: Engoulevent d'Hispaniola

Spanish: Chotacabras de la Española

German: Hispaniolanachtschwalbe

Other common names: (Greater) Antillean Nightjar (with *C. cubanensis*)

Taxonomy. *Antrostomus ekmani* Lönnberg, 1929, near Jérémie, Haiti.

May form superspecies with *C. cubanensis*, with which it was until recently considered conspecific, but notable differences in voice. Monotypic.

Distribution. Hispaniola.

broader white (male) or buff (female) tips to three outermost tail feathers. Juvenile very dark, almost blackish. Voice. Song of male is a short "clik" or "tuc" followed by a trilled whistle that rises in pitch: "tuc, terrreo". Calls include soft "quat" and deep, crow-like "gaaw" sounds.

Habitat. Typically pine forests, from possibly sea-level to 1500 m.

Food and Feeding. Feeds on insects. Foraging methods not described.

Breeding. Breeding habits almost entirely undocumented. Breeds Apr-Jul; almost fully grown chicks in mid-Aug. No nest, eggs laid on ground; one brood of two chicks found on overgrown forest path. Clutch generally 2 eggs, pale greenish-white, spotted brown; chick not described.

Movements. None recorded. Sedentary.

Status and Conservation. Not globally threatened. Locally widespread in suitable habitat throughout Haiti and Dominican Republic, though probably not common at any locality; fairly common in Sierra de Bahoruco National Park.

Bibliography. Anon. (1998a), Bond (1985), Dod (1987), Garrido & Reynard (1994, 1998), del Hoyo (1999), Lönnberg (1929), Raffaele *et al.* (1998), Stotz *et al.* (1996), Wetmore & Swales (1931).

30. Tawny-collared Nightjar

Caprimulgus salvini

French: Engoulevent de Salvín

German: Salvinnachtschwalbe

Spanish: Chotacabras Ticuer

Other common names: Salvín's Chuck-will, Chipwillow

Taxonomy. *Caprimulgus salvini* Hartert, 1892, no locality = Mirador, Veracruz, Mexico.

Forms superspecies with *C. badius* and *C. sericocaudatus*, all three sometimes being considered conspecific. Monotypic.

Distribution. E Mexico.

Descriptive notes. 23-25.5 cm. Sexually dimorphic. Upperparts blackish-brown boldly streaked and spotted blackish, with indistinct tawny or buff nuchal collar; wing-coverts blackish-brown,

Descriptive notes. 25-29.5 cm; male 68-80 g, female 50-70 g. Sexually dimorphic. Upperparts blackish-brown, speckled greyish-brown, greyish-white and pale buff; crown broadly streaked blackish, no nuchal collar; wing-coverts blackish-brown, speckled and spotted pale buff; scapulars buffish-white, speckled brown and boldly spotted blackish-brown; buffish-white submoustachial stripe and broad pale buff band around lower throat; underparts buffish-white, speckled and spotted blackish-brown, becoming buff vermiculated brown on undertail-coverts; both sexes lack white markings on wings. Male has white tips to three

to three outermost tail feathers. Immature plumages not described. Voice. Song of male is a rapid "chip, willow", "yip, willow" or "chip, wow"; sings from perches at dusk and dawn.

Habitat. Lowland semi-deserts and dry, open woodland with scrub; occasionally also farmland and fields, thickets, forest edges and clearings. Recorded from sea-level to 500 m.

Food and Feeding. Feeds on insects. Forages from perches and possibly from ground.

Breeding. Poorly documented. Breeds Apr-Aug. Clutch 2 eggs, whitish with brown and grey markings; chick not described.

Movements. Generally sedentary, although occasionally undertakes local movements outside breeding season (Dec-Feb) to S Veracruz and N Oaxaca. A skin from N Nicaragua probably refers to this species, although sometimes referred to *C. badius*.

Status and Conservation. Not globally threatened. Generally confined to woodland and scrubland in E Mexico, where considered a common to fairly common breeding bird in lowlands. Status uncertain in SE Mexico, with record from NW Chiapas

Bibliography. Anon. (1998a), Binford (1989), Eisenmann (1955), Hardy & Straneck (1989), Howell & Webb (1995a), Lowery & Dalquest (1951), Pierson (1986), Stotz *et al.* (1996).

31. Yucatan Nightjar

Caprimulgus badius

French: Engoulevent maya

Spanish: Chotacabras Guatemalteco

German: Guatemalanachtschwalbe

Other common names: Yucatan Tawny-collared Nightjar

Taxonomy. *Antrostomus badius* Bangs and Peck, 1908, Toledo district, Belize.

Forms superspecies with *C. salvini* and *C. sericocaudatus*, all three sometimes being considered conspecific. Present species has alternatively been treated as a race of one or other of the above species, although vocally it may be closest to *C. rufus*. Monotypic.

Distribution. Yucatán Peninsula of SE Mexico; also Cozumel I.

Descriptive notes. 25-25.5 cm; 1 male 65.5 g, female 51-56 g. Sexually dimorphic. Upperparts greyish-brown, spotted and speckled greyish-white and heavily spotted and streaked blackish-brown; broad tawny-buff or rufescent nuchal collar; wing-coverts greyish-brown, spotted and speckled greyish-white, cinnamon, buff and tawny; broad buffish-white band around lower throat; underparts brownish heavily spotted white, becoming buff barred brown on undertail-coverts; both sexes lack white markings on wings. Male has broad white tips to three outermost tail feathers; female has narrow tawny-buff tips. Iris dark

brown, bill blackish, legs and feet blackish-brown. Generally paler than *C. salvini*, with nuchal collar paler and broader. Smaller and paler than *C. sericocaudatus*. Immature plumages not described. Voice. Song of male is an undulating "whee, wee-a, wee-a" or "ree-o, ree, ree", similar to that of *C. sericocaudatus*. Sings mainly at dusk and dawn. Call is a series of "chuk" notes.

Habitat. Mainly open, lowland woods and forest, and also forest edge.

Food and Feeding. Feeds on insects. Foraging methods not described.

Breeding. Almost entirely undocumented. Possibly breeds Apr-Aug. Clutch 2 eggs, elliptical, white, sparsely flecked and blotched brown and purplish-grey; chick not described.

Movements. Generally sedentary, though some S movement outside breeding season; recorded Dec-Feb in Belize. Also claimed to occur in Caribbean lowlands of Guatemala, N Nicaragua and Half Moon Cay.

Status and Conservation. Not globally threatened. In 1950's considered extremely rare and confined to deciduous forests, though probably under-recorded; currently regarded as a fairly common to common breeding bird locally, occurring in Yucatán, Quintana Roo and much of Campeche, and also on Cozumel I. Possibly an extremely rare resident in Guatemala, though validity of records often questioned; recently heard in Campeche, only 11 km from Mexican border with Guatemala. Single possible record from N Nicaragua, a museum specimen taken Apr 1917, but this is usually attributed to *C. salvini*.

Bibliography. Anon. (1998a), Davis (1979a), Gómez de Silva (1998), Hardy & Straneck (1989), Howell (1997), Howell & Webb (1995a), Klaas (1968), Land (1970), Paynter (1955), Pierson (1986), Russell (1964), Stotz *et al.* (1996), Valiely & Whitman (1997).

32. Silky-tailed Nightjar

Caprimulgus sericocaudatus

French: Engoulevent à queue de soie

Spanish: Chotacabras Coladeseda

German: Seidennachtschwalbe

Taxonomy. *Antrostomus serico-caudatus* [sic] Cassin, 1849, Rio de Janeiro, Brazil.

Forms superspecies with *C. salvini* and *C. badius*, all three sometimes being considered conspecific. *C. rufus saltarius* initially thought to belong in present species, but might alternatively be separate species or merely colour morph of *C. r. rutilus*. Two subspecies recognized.

Subspecies and Distribution.

C. s. mengeli Dickerman, 1975 - N Brazil, N Peru and NW Bolivia.

C. s. sericocaudatus (Cassin, 1849) - SE Brazil, E Paraguay and extreme NE Argentina.

Descriptive notes. 24-30 cm; male 62-83 g, female 53-66 g. Sexually dimorphic. Upperparts dark greyish-brown, broadly streaked and spotted blackish-brown; very broad but indistinct tawny-buff nuchal collar; wing-coverts brown, spotted buff and cinnamon; large buff or buffish-white patch on lower throat; underparts brown, boldly spotted whitish; both sexes lack white markings on wings. Male has whitish tips to three outermost tail feathers; female has narrow buff tips. Iris dark brown, bill blackish, legs and feet blackish-brown. Larger than *C. salvini*, with narrower white tips to three outermost tail feathers. Larger and generally

darker than *C. badius*, with a broader but less conspicuous rufescent nuchal collar; male has narrower white tips to three outermost tail feathers. Immature similar to adult, but has narrower white or buff tips to three outermost tail feathers. Race *mengeli* smaller and darker. VOICE. Song of male is an undulating "doh, wheo, eeo" given from low perches, mainly at dusk and dawn. Calls include treble-noted "gawrr, a gawrr", or longer "gawrr, a gawrr, a gawrr". Song of race *mengeli* is more melodious, drawn out and higher pitched: "doh, wheeo, wheeo".

Habitat. Mainly forest, in clearings, especially where there are thickets, bamboo understorey or second-growth, and along forest edge. Nominant race occurs in subtropical evergreen forest; *mengeli* prefers tropical rainforest.

Food and Feeding. Feeds on beetles, crickets, grasshoppers and ants. Foraging methods not described.

Breeding. Almost entirely undocumented. No nest, eggs laid on leaf litter on ground. Eggs elliptical; chick not described.

Movements. None documented. Sedentary.

Status and Conservation. Not globally threatened. Generally uncommon and little known. Widely but sparsely distributed in Peru; widespread and possibly rare to fairly common in E Paraguay; locally uncommon to fairly common in NE Argentina. Loss of habitat through deforestation possibly poses greatest threat in many regions.

33. Buff-collared Nightjar *Caprimulgus ridgwayi*

French: Engoulevent de Ridgway **Spanish:** Chotacabras Tucuchillo

German: Brauhals-Nachtschwalbe

Other common names: Ridgway's Whip-poor-will, Cookachea, Tucuchillo

Taxonomy. *Antrastomus ridgwayi* Nelson, 1897, Guerrero, Mexico.

Two subspecies recognized.

Subspecies and Distribution.

C. r. ridgwayi (Nelson, 1897) - extreme SW USA and W & S Mexico.

C. r. troglodytes Griscom, 1930 - C Guatemala, C Honduras and C Nicaragua.

Descriptive notes. 21.5-24.5 cm; male 45-54 g, female 45-53 g. Sexually dimorphic. Upperparts greyish-brown streaked blackish-brown; crown boldly spotted blackish-brown; broad tawny or buff nuchal collar; wing-coverts greyish-brown, streaked and spotted blackish-brown, and speckled and spotted greyish-buff and buff; scapulars greyish-brown, boldly spotted blackish-brown edged tawny or cinnamon; narrow buffish-white supercilium and moustachial stripe; broad buffish-white band around lower throat; underparts greyish-brown tinged cinnamon, streaked and speckled brown, becoming pale buff barred brown on belly and

flanks; both sexes lack white markings on wings. Male has broad white tips to three outermost tail feathers; female has narrow buffish tips. Iris brown, bill blackish, legs and feet brownish. Generally paler than *C. vociferus*, with broader tawny-buff nuchal collar. Immature similar to adult. Race *troglodytes* is smaller and often has scapulars more boldly spotted cinnamon or tawny. VOICE. Song of male is an accelerating "cuk, cuk, cuk, cuk, cuk, chuka-cheea" or "tok, tok, tek, tek, tek, teeka-teea", ascending slightly in pitch. Sings from ground, rocks or low perches. Call is a descending series of deep, guttural "tuk" notes.

Habitat. Typically rocky, arid or semi-arid areas, in deciduous forest, mixed forest of pine and oak, second-growth forest, woodland, scrubland, fields and thickets. Also on rock-strewn hillsides with scattered vegetation. Tends to avoid areas where rocks and vegetation are absent. Recorded from sea-level to 2400 m.

Food and Feeding. Feeds on beetles, moths and other insects. Hunts by making short flycatching sallies from ground or elevated perches, including tree branches and cliff faces; also forages low over open ground.

Breeding. Poorly documented. Possibly breeds Mar-Aug in SW USA and Mexico. Territorial. Nest-site often partly shaded by vegetation; no nest, eggs laid on leaf litter or rocky ground. Clutch 2 eggs, elliptical, buff, blotched brown and lilac; chick semi-precocial; adults flushed from nest-site may perform injury-feigning distraction display.

Movements. Poorly known. Nominant race sedentary in S of range, partly migratory in N, small numbers summering (May-Aug) in SE Arizona and SW New Mexico. Race *troglodytes* largely sedentary.

Status and Conservation. Not globally threatened. Possibly undergoing a slight range expansion to N. Probably rare summer visitor in SW USA, where first reported in 1958 and recorded only from Pima, Santa Cruz, Pinal and Cochise counties in SE Arizona and from Hidalgo and Dona Ana counties in New Mexico. Collecting of specimens banned from US locations; proposed as Species of Concern by Arizona Game and Fish Department, and since Jan 1975 listed as endangered in New Mexico by New Mexico Department of Game and Fish. Fairly common to common in Mexico, mainly on W side from Sonora and Chihuahua S to Oaxaca; local in C & S Veracruz and Chiapas. Major threat in some regions, especially in E of Mexican range, probably loss of habitat due to land

clearance for cattle rearing. Uncommon resident in Motagua Valley, C Guatemala, and rare to uncommon in Honduras. Potential predators include birds of prey, owls (Strigidae) and bobcats (*Lynx rufus*), while eggs and chicks might be taken by snakes, skunks (Mustelidae), foxes (Canidae), ringtails (*Bassaris astutus*) and white-nosed coatis (*Nasua narica*). In some regions, small numbers are occasionally killed by traffic on roads.

Bibliography. Álvarez del Toro (1949), Baicich & Harrison (1997), Binford (1989), Bowers & Dunning (1997), Davis (1957), Griscom (1929, 1930), Howell & Webb (1990, 1995a), Jenkinson & Mengel (1970), Johnston & Hardy (1959), Kaufman (1996), Land (1970), Levy (1962), Monroe (1968), Nicol & Arnott (1974), Pyle (1995), Rowley (1962), Schaldach (1963), Short (1974), Stotz *et al.* (1996), Sutton (1951a).

34. Whip-poor-will *Caprimulgus vociferus*

French: Engoulevent bois-pourri

Spanish: Chotacabras Cuerporruín

German: Schwarzkehl-Nachtschwalbe

Other common names: Northern Whip-poor-will (*vociferus*); Mexican Whip-poor-will (*arizonae* group)

Taxonomy. *Caprimulgus vociferus* Wilson, 1812, Pennsylvania.

May form superspecies with *C. noctitherus*, with which formerly considered conspecific. Differences in vocalizations suggest that Central American races may be better split from nominate, as *C. arizonae*. Six subspecies currently recognized.

Subspecies and Distribution.

C. v. vociferus Wilson, 1812 - SC & SE Canada and EC & E USA; winters from SC & SE USA through Central America.

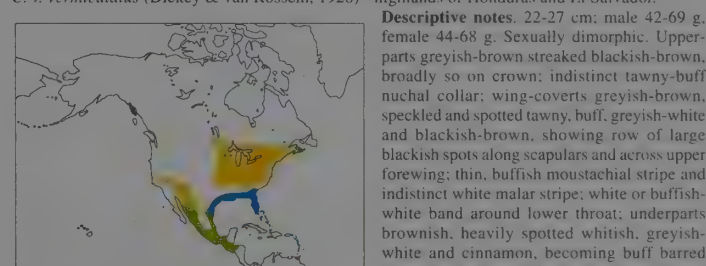

C. v. arizonae (Brewster, 1881) - SW USA S to C Mexico; winters in C Mexico.

C. v. setosus van Rossem, 1934 - E Mexico.

C. v. oaxacae (Nelson, 1900) - SW Mexico.

C. v. chiapensis (Nelson, 1900) - SE Mexico and highlands of Guatemala.

C. v. vermiculatus (Dickey & van Rossem, 1928) - highlands of Honduras and El Salvador.

Descriptive notes. 22-27 cm; male 42-69 g, female 44-68 g. Sexually dimorphic. Upperparts greyish-brown streaked blackish-brown, broadly so on crown; indistinct tawny-buff nuchal collar; wing-coverts greyish-brown, speckled and spotted tawny, buff, greyish-white and blackish-brown, showing row of large blackish spots along scapulars and across upper forewing; thin, buffish moustachial stripe and indistinct white malar stripe; white or buffish-white band around lower throat; underparts brownish, heavily spotted whitish, greyish-white and cinnamon, becoming buff barred brown on belly and flanks; both sexes lack

white markings on wings. Male has broad white tips to three outermost tail feathers; female has narrow buff tips. Iris dark brown, bill dark brown or blackish, legs and feet brownish. Smaller than *C. carolinensis* with less apparent spotting; male has much more white on outermost tail feathers; female has more readily apparent buff tips to tail feathers. Darker than *C. ridgwayi*, with narrower, less distinct tawny nuchal collar. Much paler and more uniformly patterned than *C. saturatus*. Larger and paler than *C. noctitherus*. Immature similar to adult but often buffier. Races vary somewhat in overall coloration and in size. VOICE. Song of male is a whistled "whip, pr-will" or "whip, pr-weee", last note usually rising in pitch at end, and is often preceded by or interspersed with several short, sharp "quirt" notes; song of W race *arizonae* is more liquid and melodious. Sings from perches and ground, mainly at dusk and dawn and on moonlit nights. Flight/contact call of race *arizonae* is repetitive "hu-whip"; alarm/distress calls include short "cook", soft "whip-will" or "whip" notes; other calls include soft "coo" or "cook" notes, melodious "coo-eu" or "coo-eu-ah" calls, guttural chuckles, "cur, cur, cur" and soft "quirt-quirt"; guttural hissing sounds are given during threat/defence displays.

Habitat. All types of forest and open woodland, especially of oak or mixed pine and oak. Tolerates both arid and more humid conditions, from lowlands to montane altitudes. Also in suburban habitats, and on migration in coastal scrub. Race *arizonae* occurs in lowland oak woods and mixed forest of oak and sycamore, in highland woods of yellow pine, aspen or Douglas fir (*Pseudotsuga menziesii*) and in montane spruce forest. Recorded from sea-level to 3000 m.

Food and Feeding. Feeds on moths, beetles, grasshoppers, crickets, mosquitoes, caddisflies, locusts, ants and possibly worms. Forages by making short sallies from perches or hunts in more prolonged flights, in clearings, open spaces and among trees. Often feeds near running water. May occasionally feed on ground, and may ingest grit to aid digestion.

Breeding. Breeds May-Jul in North America, mid-Mar to Jul in Mexico, and possibly late Feb to May in El Salvador; breeding often synchronized with moon phases. Often double-brooded, beginning second clutch c. 33 days after first, male apparently brooding chicks of first while female attends second. Territorial. Nest-site in clearing or glade, along edge of trees or wood, or beneath vegetation, in more arid country (race *arizonae*) also below rocks, in rocky, forested ravine, or on outcrop, escarpment or steep hillside: same site may be used for several years; no nest, eggs laid on leaf litter on ground, often near or beside fallen log. Clutch 1-2 eggs, elliptical, slightly glossy, white or pale cream, and unmarked or faintly marked pinkish and brownish or blotched and irregularly spotted brown, purple and lilac, laid on consecutive days; incubation begins with first egg, usually by female during day, with change-over at dusk, shared by both sexes during night. Female taking over again before dawn; incubation period generally 19-21 days; chick covered in cinnamon, pale brown or buff down, fading to yellowish-tan within few days; adults threatened at nest-site perform distraction display; chicks fledge after c. 15 days, usually independent after c. 30 days.

Movements. Nominant race migratory, arriving on S breeding grounds by late Mar and on N by early May. Possibly casual visitor to SW & C Canada and accidental to SE Alaska. Probably departs from breeding grounds Sept-Nov and winters in lowlands of South Carolina and Gulf States, S through E Mexico (Sept-Apr) to Guatemala, S Belize, El Salvador and Honduras. Also a casual winter visitor in S California, W Cuba, Jamaica, Costa Rica (perhaps rare on Pacific slope mid-Nov to late Mar) and W Panama (possibly 2 records, W Chiriquí), and occasionally winters along E coast of USA as far N as New Jersey. Race *arizonae* migratory, arriving on breeding grounds by late Apr and departing again by late Sept, though perhaps only an altitudinal migrant in parts of Mexican range. Casual visitor to Baja California. Generally winters in C Mexico. Other populations may be largely sedentary.

Status and Conservation. Not globally threatened. Generally very common to locally abundant throughout much of range, though decreasing in many regions in N. Declining in some areas in

Ontario: locally fairly common in Massachusetts but numbers falling; in Connecticut, common before 1920's but steady decline after 1930's, now considered locally rare to uncommon and designated as Species of Special Concern. Slowly declining in Ohio; becoming less common in Vermont; local decreases noted in W Virginia since 1950's and now absent from some regions; declined in Michigan and New York State; in Pennsylvania, decreased in last 50 years and now disappeared from some regions. Fairly common to common throughout much of C Mexico, numbers increasing in non-breeding season with arrival of migrants from farther N, although birds from North American populations apparently winter more to E. Fairly common in Guatemalan highlands; rare resident in El Salvador, although N migrants are common in winter; very rare and casual winter visitor to Pacific side of Costa Rica; extremely rare winter visitor to W Chiriquí highlands, W Panama. In N breeding populations, reasons for decline include loss of habitat to agriculture and urbanization, industrial pollution and use of insecticides which may affect food availability, increasing road traffic, predation by domestic cats, and disturbance at nest-sites by people and dogs.

35. Puerto Rican Nightjar

Caprimulgus noctitherus

French: Engoulevent de Porto Rico

Spanish: Chotacabras Portorriqueño

German: Puerto-Rico-Nachtschwalbe

Taxonomy. *Setochalcis noctitherus* Wetmore, 1919, Bayamón, Puerto Rico.

May form superspecies with *C. vociferus*, with which formerly considered conspecific. Monotypic. **Distribution.** SW Puerto Rico.

Descriptive notes. 22-22.5 cm; unsexed 35-37 g. Sexually dimorphic, though not strongly so. Upperparts greyish-brown tinged rufous and streaked blackish-brown, broadly so on crown; indistinct tawny-buff nuchal collar; wing-coverts greyish-brown, speckled and spotted buff, tawny and greyish-white, showing row of large blackish spots across upper forewing and along scapulars; white or buffish-white band around lower throat; underparts brownish, heavily spotted greyish-white and cinnamon, becoming buff barred brown on belly and flanks; both sexes lack white markings on wings. Male has broad white tips to three outermost tail feathers; female has narrow, buffish tips. Iris dark brown, bill blackish, legs and feet blackish-brown. Immature paler than adult. **Voice.** Song of male is a rapid series of short, liquid whistles, "whlip, whlip, whlip, whlip, whlip", often preceded by faint "quert" notes. Sings from perches throughout night. Calls include short growls, "quert" and "gaw" notes, and soft, clucking or guttural sounds; gives guttural hissing sounds during threat/defence displays.

Habitat. Typically semi-deciduous forest with hardwood trees and little or no ground vegetation, usually on dry, limestone soils; also dry, open secondary growth with scrub, xeric or dry scrubland, open scrub forest, and forest with tangled, thorny undergrowth. Occasionally frequents plantations of *Eucalyptus robusta*. Avoids riparian forest, and is found in disturbed areas only where canopy is still intact. A lowland species, recorded from sea-level to 230 m.

Food and Feeding. Feeds on beetles, moths and other insects. Forages by making flycatching sallies from perches and hunts beneath tree canopy. Smaller prey items are probably consumed in flight, but larger insects are carried in bill back to perch where they are shaken and swallowed. Also feeds on insects attracted to artificial lights, where birds often fly through insect swarms with gapes open, or land on ground with wings outstretched, to pick up beetles. Immature birds may forage by making short sallies from ground, and may feed on ground itself.

Breeding. Breeds late Feb-Jul (mainly Apr-Jun), apparently influenced by moon phase. Possibly double-brooded. Territorial. Nest-site usually partly shaded, beneath scrub vegetation in woodland

where canopy height 4-6 m, or at base of small tree; no nest, eggs laid on leaf litter on ground. Clutch 1-2 eggs, elliptical, buffish-brown, blotched and spotted purple, with markings denser around blunt end; incubation by both sexes, male incubating more than female during day, period generally 18-21 days; eggs hatch asynchronously, chick semi-precocial, covered in reddish-buff or cinnamon down, generally brooded by male, can fly short distances after c. 14 days; adults threatened at nest-site perform injury-feigning distraction display.

Movements. None recorded. Sedentary.

Status and Conservation. CRITICALLY ENDANGERED. Restricted-range species; present in Puerto Rico and the Virgin Islands EBA. Long thought to be extinct until rediscovered in 1961. Population in 1984 estimated at 670-800 pairs: Guánica forest c. 324 pairs (c. 1 pair per 8 ha above 75 m and c. 1 pair per 18-8 ha between 25-75 m), Susúa forest c. 68 pairs (1 pair per 8-1 ha N of Carretera del Bosque and 1 pair per 24-5 ha S of Carretera del Bosque), and Guayanilla hills c. 263 singing males. Studies in 1985-87, 1989-90 and 1992 produced total of 712 singing males in 9839 ha: 347 in Guánica area, 177 in Susúa-Maricao area and 188 in Guayanilla area. Current population possibly numbers 1400-2000 individuals in c. 10,000 ha of coastal dry and cordillera forest in SW Puerto Rico. Loss of habitat through deforestation is a possible reason for current, restricted range; potential predators include feral cats and introduced mongooses (*Herpestes erpuncatus*).

Bibliography. Anon. (1998a), Binggi (1983), Bond (1985), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Díaz (1983), Greenway (1967), Johnson (1988), Kepler & Kepler (1973), King (1978/79), Noble (1988), Noble *et al.* (1986a, 1986b), Raffaele (1989), Raffaele *et al.* (1998), Reynard (1962), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Vilella (1989, 1990, 1995a, 1995b), Vilella & Zwank (1987, 1988, 1993a, 1993b), Wetmore (1919).

36. Dusky Nightjar

Caprimulgus saturatus

French: Engoulevent montagnard

Spanish: Chotacabras Fuliginoso

German: Bergnachtschwalbe

Other common names: Sooty Nightjar

Taxonomy. *Antrostomus saturatus* Salvin, 1870, Volcán de Chiriquí, Panama. Monotypic.

Distribution. C highlands of Costa Rica to W Panama.

Descriptive notes. 21-25 cm; 1 male 53 g, 1 female 51 g. Sexually dimorphic. Upperparts and wing-coverts blackish-brown, heavily spotted tawny and buff, no nuchal collar; indistinct pale buffish band around lower throat; underparts blackish-brown heavily spotted tawny, becoming dark buff barred brown and spotted whitish on belly and flanks; female often paler and more rufous than male; both sexes lack white markings on wings. Male has broad white tips to three outermost tail feathers; female has narrow tawny-buff tips. Iris dark brown, bill blackish, legs and feet greyish or dark brownish. Immature similar to adult

but paler and more rufous. **Voice.** Song of male is a trilled whistle, "prurrrrr, prurree" or "prurrrrr, prurwhip", first note evenly pitched, second rising in pitch at end. Sings from perches and possibly also from ground, mainly at dusk and dawn. Flight calls are scratchy "wheer" sounds.

Habitat. Mainly montane forest or woodland, in clearings and areas of second growth or along forest edges; also upland pastures with scattered trees. Recorded at 1500-3100 m.

Food and Feeding. Feeds on moths and beetles. Forages from perches, hunting over open spaces in or near woods and forests.

Breeding. Poorly known. Possibly breeds Feb-Apr (juveniles found in Apr). Nest-site in clearing with scattered trees, often among tall grass and ferns; no nest, egg laid on leaf litter or grass, on ground. Clutch possibly 1 egg, elliptical, dull or glossy white; chick not described.

Movements. None recorded. Sedentary.

Status and Conservation. Not globally threatened. Restricted-range species; present in Costa Rica and Panama Highlands EBA. Locally common and widespread in C highlands of Costa Rica, uncommon in forested highlands of W Chiriquí, W Panama. Present in Volcán Poás National Park and Monteverde Biological Reserve (Costa Rica).

Bibliography. Anon. (1998a), Blake (1958), Hernández-Baños *et al.* (1995), Marin & Schmitt (1991), Ridgely & Gwynne (1989), Slud (1964), Stattersfield *et al.* (1998), Stiles & Skutch (1989), Stotz *et al.* (1996), Wetmore (1968a).

37. Band-winged Nightjar

Caprimulgus longirostris

French: Engoulevent à miroir **German:** Spiegelnachtschwalbe **Spanish:** Chotacabras Ñañarca
Other common names: Rufous-naped Nightjar (*ruficervix*)

Taxonomy. *Caprimulgus longirostris* Bonaparte, 1825, South America. Race *ruficervix* has sometimes been treated as a separate species, but geographical variation in voice remains too poorly known to provide a clear picture of the relationships. Seven subspecies currently recognized.

Subspecies and Distribution.

C. l. ruficervix (P. L. Sclater, 1866) - W & N Venezuela, W Colombia and Ecuador.
C. l. roraimae (Chapman, 1929) - Pantepui of S Venezuela.
C. l. atripunctatus (Chapman, 1923) - C & S Peru, C & SW Bolivia, NW Argentina and N Chile.
C. l. decussatus Tschudi, 1844 - SW Peru and extreme N Chile.
C. l. bifasciatus Gould, 1837 - Chile and W Argentina.
C. l. longirostris Bonaparte, 1825 - SE Brazil, NW & C Paraguay, NE Argentina and Uruguay.
C. l. patagonicus Olog, 1962 - C & S Argentina.

Descriptive notes. 20-27 cm; male 29-50 g, female 32-71 g. Sexually dimorphic. Upperparts greyish-brown streaked blackish-brown, or blackish-brown mottled tawny, buff and greyish-white; broad tawny or buffish nuchal collar; wing-coverts greyish-brown or blackish-brown, boldly spotted buff, pale buff or greyish-buff; scapulars blackish-brown, boldly spotted buff; a large white (male) or buffish (female) patch around lower throat; underparts brownish, barred and spotted buff, becoming buff barred brown on belly and flanks. Male has white band across four outermost primaries and broad white tips to three or four outermost.

most tail feathers, with white bar across upper half of inner webs; female has narrow buffish or buffish-white wing band, and either lacks white on tail or has indistinct whitish spot on inner webs of one or two outermost tail feathers. Iris brown, bill blackish, legs and feet blackish-brown. Larger and somewhat paler than *C. whitelyi*, which lacks a nuchal collar and has different wing and tail markings. Immature similar to adult but plainer, with narrow tawny wing bands. Two racial groups recognized: blackish and spotted forms (*ruficervix*, *roraimae*, *atripunctatus*) and greyish-brown and streaked forms (*decussatus*, *bifasciatus*, *longirostris*, *patagonicus*); some races differ slightly in size and all are extremely variable in coloration and markings. **VOICE.** Song of male is a repetitive, high-pitched whistle, "seeeeeert", that can be quite variable. Singing from low perches or ground, mainly at dusk and dawn. Flight calls are thin, high-pitched "cheet" notes, also nasal "tchree-ee", e.g. when flushed.

Habitat. Typically inhabits forest edges, woodland borders, open woodland, clearings, arid bush and campos. Also occurs in a wide variety of other habitats, including open areas with low vegetation, shrubby páramos, puna grassland, deserts and stony semi-deserts, steppe country and grassy slopes in semi-arid elfin forest; sometimes found in towns and cities. Recorded from sea-level up to 4200 m.

Food and Feeding. Feeds on moths, beetles and termites. Forages by making short sallies from ground or low perches. Also feeds on insects attracted to artificial lights.

Breeding. Possibly breeds Feb-Sept in W Venezuela, Mar-Nov in Colombia, up to and from late Jul in Ecuador, from Nov in Chile and C Argentina, and Sept-Oct in SE Brazil. Nest-site located among regenerating vegetation on burnt ground, beside road, at cliff base, among vegetation in semi-arid country, or on roof of old building; no nest, eggs laid on bare ground, leaf litter or bare rock. Clutch 1-2 eggs, elliptical or subelliptical, pinkish, creamy-pink or whitish, speckled and scrawled brown, lilac and grey, or unmarked; chick not described.

Movements. Poorly understood. Nominate race may be sedentary in N of range, migratory in S, as possibly this race occurs in Paraguay late May to late Aug as a probable migrant from S. No movements documented for subspecies *ruficervix*, *roraimae*, *decussatus* and *atripunctatus*, which may be largely sedentary. Race *bifasciatus* partly migratory, S birds moving N after breeding season to winter in chaco of N Argentina. Race *patagonicus* also partly migratory, S birds moving N and wintering in NE Argentina (Buenos Aires N to Formosa).

Status and Conservation. Not globally threatened. Uncommon migrant in parts of range, common breeding bird in many others. In Colombia, widespread and quite common; in Paraguay, apparently a fairly common winter visitor locally, though not recorded before 1979, possibly due to lack of coverage rather than a change in range; uncommon in Atlantic forest region, Brazil; widespread and probably not uncommon throughout much of Argentina and Chile.

Bibliography. Araya & Chester (1993), Belton (1984), Butler (1979), Canevari *et al.* (1991), Chapman (1931), Contreras & González (1991), Contreras *et al.* (1990), Davis *et al.* (1994), Fjeldså & Krabbe (1990), Fjeldså & Mayer (1996), Gilliard (1941), Hayes (1995), Hayes *et al.* (1994), Herzog *et al.* (1997), Hilty & Brown (1986), Johnson (1967), Kiff *et al.* (1989), Klimaitis & Moschione (1987), Koepcke (1970), Marín *et al.* (1989), Mayr & Phelps (1967), Meyer de Schauensee & Phelps (1978), Narosky & Yaurieta (1993), Nellar (1993), Parker & Goerck (1997), Parker *et al.* (1982), de la Peña (1994), Remsen & Traylor (1989), do Rosário (1996), Schubart *et al.* (1965), Sick (1979, 1993, 1997), Storer (1989), Stotz *et al.* (1996), Straube (1990), Todd & Carriker (1922), Wetmore (1926), Willard *et al.* (1991), Willis & Oniki (1993), Zimmer (1930).

38. White-tailed Nightjar

Caprimulgus cayennensis

French: Engoulevent coré **Spanish:** Chotacabras Coliblanco
German: Weißschwanz-Nachtschwalbe
Other common names: Cayenne Nightjar(!)

Taxonomy. *Caprimulgus cayennensis* J. F. Gmelin, 1789, Cayenne. Has been considered to have close affinities with *C. candicans*, forming superspecies or possibly even conspecific, but available evidence suggests that they may not be closely related. Species formerly listed as *C. albicauda*. Six subspecies recognized.

Subspecies and Distribution.

C. c. albicauda (Lawrence, 1875) - SE Costa Rica E to NW Colombia.
C. c. apertus J. L. Peters, 1940 - W Colombia S to extreme N Ecuador.
C. c. insularis (Richmond, 1902) - extreme NE Colombia, NW Venezuela, Margarita I and islands of Curaçao, Aruba and Bonaire.
C. c. manati (Pinchon, 1963) - Martinique.
C. c. leopetes Jardine & Selby, 1830 - Trinidad, Tobago, Bocas Is and Little Tobago.
C. c. cayennensis J. F. Gmelin, 1789 - EC & NE Colombia E through Venezuela, the Guianas and probably extreme N Brazil.

Descriptive notes. 20-22.5 cm; male 30-40 g, female 25-46 g. Sexually dimorphic. Upperparts greyish-brown, streaked blackish-brown; broad tawny-buff nuchal collar; wing-coverts greyish-brown, heavily spotted white, buff and pale buff; supercilium buffish or white, often indistinct; submoustachial stripe buffish or white. Male has thin whitish line across forewing, large white throat patch, buffish breast heavily spotted white, and white belly; female has buffish throat patch and is generally darker and buffier on underparts. Male shows a white band across four outermost primaries and a largely white tail; female lacks

white on wings and tail. Iris dark brown, bill blackish, legs and feet blackish-brown. Has more distinct nuchal collar than *C. parvulus*; supercilium more strongly marked, and tail more rounded; male shows paler underparts. Differs from *C. maculicaudus* in narrower, less pronounced supercilium and paler crown; also in white markings on wings. Immature plumages not described. Races generally vary in size, colour of nuchal collar and overall coloration; considerable colour variation even within nominate race. **VOICE.** Advertising call of male is a series of short, high-pitched whistles: "pt-cheeeeeee". Singing from low perches, mainly at dusk and dawn. Flight calls are high-pitched "see-see" notes; other calls include soft "tic-tic" or "wut-wut-wut".

Habitat. Typically open grassland and savanna with scattered vegetation, scrubland and along forest edges; also grassy hillsides with scattered bushes, pastures and large clearings such as airstrips. Occurs from sea-level up to possibly 3200 m.

Food and Feeding. Feeds on moths, beetles, bugs, damselflies, crickets and grasshoppers. Forages by making short sallies from ground, or by hunting low over vegetation and among animals.

Breeding. Breeds Feb-Jun in Costa Rica, Mar-Jul in Colombia, possibly Apr-Jun in Venezuela, Feb-Dec in Surinam, Jan-Jun on Trinidad, Feb-Jun on Tobago, and late Jan to Jul on Martinique. Nest-site recorded in rough grass and on gravel with nearby vegetation on Trinidad, on sparsely vegetated sandy ground in Surinam, on bare, stony ground near trees or in open savanna on Martinique; no nest, eggs laid on ground. Clutch 1-2 eggs, elliptical, pinkish-buff or creamy, scrawled, blotched or spotted lilac, grey and reddish-brown, markings denser around blunt end; incubation by female during day; chick semi-precocial; adults flushed from chicks perform injury-feigning distraction display.

Movements. Largely sedentary, although has occurred as a vagrant on Puerto Rico.

Status and Conservation. Not globally threatened. Fairly common throughout much of range, though local and uncommon in Panama, and scarce on Aruba, Curaçao and Bonaire (Netherlands Antilles). In Costa Rica, locally widespread on Pacific slope from Guanacaste southwards but status unclear on Caribbean slope; fairly common and widespread in Trinidad and Tobago, also occurring on Bocas Is and Little Tobago; probably not uncommon on Martinique, especially in E coastal plains, Caribbean lowlands and Lamentin plain along Gagneron embankment. Fairly common in Colombia, especially in grasslands; rather common in Surinam, especially in open, sandy savannas; widely distributed and not uncommon in Guyana; possibly not particularly common in Ecuador, where first recorded in Imbabura province Oct 1983.

Bibliography. Benito-Espinal & Hautecastel (1988), Bond (1985), Chapman (1931), French (1991), Friedmann & Smith (1950), Gilliard (1941), Haverschmidt & Mees (1994), Herklots (1961), Hilty & Brown (1986), Meyer de Schauensee & Phelps (1978), Pinchon (1963, 1976), Raffaele *et al.* (1998), Ridgely & Gwynne (1989), Schmitt & Schmitt (1990), Sick (1993, 1997), Slud (1964), Snyder (1966), Stiles & Skutch (1989), Stotz *et al.* (1996), Tostain *et al.* (1992), Voous (1965, 1983), Wetmore (1968a).

39. White-winged Nightjar

Caprimulgus candicans

French: Engoulevent à ailes blanches **Spanish:** Chotacabras Aliblanco
German: Weißflügel-Nachtschwalbe

Taxonomy. *Stenopsis candicans* Pelzelin, 1867, Irsanga, São Paulo, Brazil. Has been considered to have close affinities with *C. cayennensis*, forming superspecies or possibly even conspecific, but available evidence suggests that they may not be closely related; current treatment requires further study, as present species may actually belong in genus *Eleothreptus*. Monotypic.

Distribution. N Bolivia, SC Brazil and E Paraguay.

Descriptive notes. 19-21 cm; male 46-51 g. Sexually dimorphic. Upperparts and inner wing-coverts pale greyish-brown, speckled, barred and streaked brown; boldly spotted blackish on crown, no nuchal collar; outer wing-coverts white, edged brown and boldly spotted blackish; scapulars greyish-brown boldly marked blackish, inner webs generally buffish; broad pale buff submoustachial stripe; row of buffish spots around lower throat; breast greyish-brown tinged chestnut and tawny, barred and speckled brown; rest of underparts white. In flight, male has whitish wings and a largely white tail; female lacks white in plumage, has scapulars more boldly marked blackish and has buffish underparts. Iris reddish-brown or chestnut, bill generally blackish with flesh-coloured base, legs and feet grey or greyish-flesh. Immature only very recently described: similar to adult but slightly browner and less greyish, with no

white on wings and tail. **Voice.** Territorial calls of male are short, undulating whistles, "tshere-she-shew"; alarm calls include similar whistles and abrupt "eek" calls.

Habitat. Typically open grasslands with scattered trees and bushes: Chaco woodland, dry open savannas, and open *cerrado* or grassland with scattered bushes, palms, termite mounds and anthills. Also in grasslands regenerating after fires. Avoids areas of tall grass. A lowland species, recorded from sea-level to 210 m.

Food and Feeding. Known to feed on beetles and moths. Forages over hillsides, hilltops and *cerrado*, including burnt areas.

Breeding. Until recently, almost unknown. Single nest known to date was found in E Paraguay, Nov 1997, in *campo sucio* grassland with *Butia paraguayensis* palms: no nest as such, with eggs laid on bare earth: site was open from above, eggs partially covered by a herb. Clutch 2 eggs, pale creamy-brown lightly covered with darker brown, and speckled greyer. Female was incubating in mid-late Nov; 1 juvenile fledged by mid-Jan.

Movements. Largely unknown, although may be migratory in parts of range.

Status and Conservation. CRITICALLY ENDANGERED. Until fairly recently, known only from two museum specimens dating from 1820's. Considered not uncommon at Das Emas National Park, Goiás, in Brazil in 1980's, and legally protected in that country. Possibly fairly common at Aguara Nu in Reserva Natural del Bosque Mbaracayú, E Paraguay, where up to 20 pairs discovered in suitable habitat Sept-Dec 1995; continued work in Jul-Nov 1997, involving marking and radio-tracking birds, gave estimated population of 30-50 birds. Male captured at Beni Biological Station in N Bolivia in Sept 1987 suggests possibility of a population in this area, though not recorded there again as yet. Seriously threatened by loss of breeding habitat to agriculture and ranching, and to grass fires, often started deliberately.

Bibliography. Anon. (1995d), Brace *et al.* (1997), Clay, Capper *et al.* (1998), Clay, Esquivel & Mazar (1999), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Davis & Flores (1994), Hayes (1995), López *et al.* (1998), Lowen, Bartrina, Brooks *et al.* (1996), Lowen, Bartrina, Clay & Tobias (1996), Lowen, Clay *et al.* (1997), Redford (1987), Ruschi (1979), Short (1975), Sick (1993, 1997), Stotz *et al.* (1996), Tobias & Lowen (1996), Wege & Long (1995), Willis (1992).

40. Spot-tailed Nightjar

Caprimulgus maculicaudus

French: Engoulevent à queue étoilée

Spanish: Chotacabras Colipinto

German: Fleckschwanz-Nachtschwalbe

Other common names: Pitsweet

Taxonomy. *Stenopis maculicaudus* Lawrence, 1862, Pará, Brazil.

Considered by some authors sufficiently distinctive to merit isolation in a separate genus, in which case *Antius* is available. Disjunct populations could represent more than one species. Monotypic.

Distribution. Discontinuously from SE Mexico to the Guianas; and discontinuously from NW & N Brazil S through SE Peru, N & EC Bolivia to E Paraguay and SE Brazil.

Descriptive notes. 19-21.5 cm; male 28-35 g, female 26-39 g. Sexually dimorphic. Crown blackish-brown spotted buff or tawny; upperparts brown or greyish-brown, barred and vermiculated dark brown, buff and tawny; distinct buff or tawny nuchal collar; wing-coverts brown heavily speckled pale buff and boldly spotted buff or cinnamon, with broad buffish line along scapulars; broad buff supercilium, thin buff submoustachial stripe, triangular blackish malar stripe and small buff or cinnamon-buff throat patch; breast brownish, spotted buff, cinnamon-buff or buffish-white; distinct cinnamon rufous band, thinly barred brown, on lower breast and upper belly; rest of underparts buff indistinctly barred brown.

Both sexes lack white markings on wings, but may show thin buff trailing edge to inner wing. Male has broad white tips to all but central pair of tail feathers, and white spot along inner webs of four outermost tail feathers (noticeable only on fanned tail); female has no white in tail. Iris brown, bill blackish, legs and feet greyish. Differs from *C. cayennensis* in darker crown and more pronounced supercilium; male lacks white wing band of that species and has less white in tail, while both sexes show buffish trailing edge to inner wing. Differs from *C. parvulus* by more distinct nuchal collar, and throat patch less distinct and cinnamon-buff, not white; supercilium much more distinct; also male lacks white wing spots of that species, and both sexes have buffish trailing edge to inner wing. Immature similar to adult. **Voice.** Song of male is a repetitive, high-pitched "t-seet", song notes variable, given from ground or low perches, mainly at dusk. Calls include rapidly repeated "t-seet", accelerating "t-seet, seet-seet" and shrill "seeu" or "see-ee-eei" notes.

Habitat. Mainly savanna and grassland with scattered trees and thickets; also bushy pastures, open marshy country, clearings, second growth, and woodland edges. In Brazil also found in burnt groves, in Honduras and NE Nicaragua recorded in pine savanna, and in Venezuela possibly frequents rainforest. Recent records from Paraguay come from marshy valley and nearby drier hill slopes adjacent to gallery forest. Reported from sea-level to 500 m.

Food and Feeding. Feeds on beetles, moths, flies, bugs, Orthoptera and damselflies. Forages by making flycatching sallies from ground.

Breeding. Breeds late Mar to Jul in Mexico, Oct-Jan in Surinam, and possibly late Feb to May in Colombia; data from other regions unavailable. No nest, eggs laid on ground, often in open, grassy area close to low bushes. Clutch 2 eggs, buff or creamy-pink, spotted or flecked reddish-brown and pale lilac, markings heavier at blunt end; chick semi-preocial, covered in blackish down with brownish-buff markings; adults flushed from chicks may perform distraction display.

Movements. Sedentary throughout much of South American range, though small population migratory, occurring as breeding summer visitor to parts of Central America, e.g. SE Mexico (late Mar to Aug). Recorded in C Honduras (L. Yojoa) as migrant only.

Status and Conservation. Not globally threatened. Fairly common locally in many parts of range, though probably under-recorded in many regions. Locally common to fairly common in SE Mexico, though possibly breeding visitor only, wintering areas remaining unknown; possibly not common in Colombia; widespread but local in Brazil, especially in S; recently reported from E Paraguay, where 2 birds noted in Reserva Natural del Bosque Mbaracayú, Sept 1995.

Bibliography. Binford (1989), Blake (1949), Dubs (1992), Forrester (1993), Haffer (1975), Haverschmidt & Mees (1994), Hilty & Brown (1986), Howell & Webb (1995a), Kirwan & Sharpe (1999), Lowen, Bartrina, Brooks *et al.* (1996), Lowen, Clay *et al.* (1997), Meyer de Schauensee & Phelps (1978), Monroe (1968), Parker *et al.* (1982), Rensen & Traylor (1989), Ridgely & Gwynne (1989), Schubart *et al.* (1965), Sick (1993, 1997), Snyder

(1966), Stotz *et al.* (1996), Tostain (1980), Tostain *et al.* (1992), de Urioste (1994), Willis (1992), Willis & Oniki (1993), Zimmerman (1957b).

41. Little Nightjar

Caprimulgus parvulus

French: Engoulevent des bois

German: Zwernachtschwalbe

Spanish: Chotacabras Chico

Taxonomy. *Caprimulgus parvulus* Gould, 1837, near Santa Fé, River Paraná, Argentina.

Formerly considered conspecific with *C. anthonyi*, but differs in vocalizations. Birds of Santa Marta region (N Colombia) have been considered a separate species, *C. heterurus*, again on basis of vocal differences, but these are normally considered insufficiently marked to justify such a split. Two subspecies currently recognized.

Subspecies and Distribution.

C. p. heterurus (Todd, 1915) - N Colombia and NW & CE Venezuela.

C. p. parvulus Gould, 1837 - E Peru through Brazil (S of Amazon) and S to N Argentina and Uruguay.

Descriptive notes. 19-21 cm; male 25-42 g, female 36-46 g. Sexually dimorphic. Upperparts greyish-brown streaked blackish-brown, broadly so on crown; broad but indistinct buff or tawny-buff nuchal collar; wing-coverts greyish-brown, barred, spotted and speckled buff, tawny, rufous and whitish; scapulars blackish-brown, broadly edged buff or pale buff on outer webs; no supercilium but large white throat patch; underparts greyish-brown spotted pale buff and greyish-white, thinly barred light brown, becoming buff barred brown on belly and flanks. Male has large white spot on four outermost primaries and

white tips to all but central pair of tail feathers; female generally lacks white. Iris dark brown, bill blackish, legs and feet brownish-olive or greyish-olive. Differs from *C. maculicaudus* by less marked nuchal collar, much fainter supercilium, and large white throat patch; male also by white markings in wings; from *C. cayennensis* by somewhat less distinct nuchal collar and supercilium, and by squarer tail; and from *C. anthonyi* by plainer scapular pattern and smaller white throat patch. Immature similar to adult female. Race *heterurus* similar, but slightly darker on underparts and commonly has larger white markings on wings and tail; overall tone of coloration apparently variable in both races, but generally fairly grey. **Voice.** Song of male is a distinctive, warbled "dop, dro-dro-dro-dro", descending in pitch; sings from perches throughout night. Song of race *heterurus* is a deeper, evenly pitched "pik, gobble-gobble-gobble-gobble".

Habitat. Varied, including open woodland and forest, lightly wooded terrain, savanna, thickets, open bush country, pastures and weedy fields with scattered bushes, and espinillo or eucalyptus groves. In Venezuela, race *heterurus* often found in slightly hilly terrain and also recorded in suburban parkland. Occurs from sea-level to 1000 m.

Food and Feeding. Feeds on moths and beetles. Foraging methods not described.

Breeding. Poorly documented. Possibly breeds from late Oct in Colombia, Oct-Nov in Paraguay, and from Nov in SW Brazil. No nest, eggs laid on ground, often near or beneath thick bush. Clutch 2 eggs, elliptical, creamy-white to buffish-white, blotched and scrawled brown, with underlying patches of lavender-grey; chick not described.

Movements. Nominate race possibly sedentary and partly migratory, though movements poorly understood. As a migrant, occurs from E Peru E to N Brazil (Pará). In E Brazil (Minas Gerais) often very common in Oct, and summer visitor only to S Brazil (late Oct to mid-Feb). Race *heterurus* probably sedentary.

Status and Conservation. Not globally threatened. Published data on status rather scarce, but in many regions often common to abundant in suitable habitat. Rare in N Colombia, though possibly under-recorded; in Brazil, common Apr-Oct in Mato Grosso, and locally common summer visitor, late Oct to mid-Feb, in W & C Rio Grande do Sul; generally rare to uncommon in much of Paraguay, though common in Alto Chaco in W; possibly not uncommon locally in N Bolivia.

Bibliography. dos Anjos *et al.* (1997), Bauer *et al.* (1997), Belton (1984), Brace & Hornbuckle (1998), Canevari *et al.* (1991), Chubb (1910), Contreras *et al.* (1990), Davis, L.L. (1979a), Davis, S.E. (1993), Donahue (1994), Dubs (1992), Hayes (1995), Hilty & Brown (1986), Meyer de Schauensee & Phelps (1978), Miserendino (1998), Narosky & Yzurieta (1993), Nellar (1993), Parker *et al.* (1982), de la Peña (1994), Rensen & Traylor (1989), do Rosário (1996), Saibene *et al.* (1996), Schubart *et al.* (1965), Schwartz (1968), Short (1975), Sick (1993, 1997), Stotz *et al.* (1996), Wetmore (1926).

42. Scrub Nightjar

Caprimulgus anthonyi

French: Engoulevent d'Anthony

Spanish: Chotacabras de Anthony

German: Equadornachtschwalbe

Taxonomy. *Setopagis anthonyi* Chapman, 1923, Portovelo, Ecuador.

Formerly considered conspecific with *C. parvulus*, but differs in vocalizations. Monotypic.

Distribution. W Ecuador and NW Peru.

Descriptive notes. 18-21 cm; male 32-39 g, female 31-42 g. Sexually dimorphic. Upperparts greyish-brown, speckled buffish and streaked blackish-brown; crown broadly streaked blackish-brown; indistinct tawny-buff nuchal collar; wing-coverts greyish-brown, speckled brown and buffish and heavily spotted buff and pale buff; scapulars blackish-brown, broadly edged buff; white throat patch; underparts greyish-brown or brown, broadly barred buff and pale buff. Male has white band across five outermost primaries and white inner webs to two outermost tail feathers; female has thinner white wing bands and less white on tail. Iris dark brown,

bill blackish, legs and feet pinkish grey-brown. Differs from *C. parvulus* in different scapular pattern and smaller white throat patch; from *C. cayennensis* by less distinct tawny-buff nuchal collar. Imma-

ture similar to adult but generally lacks white markings on wings and tail. Voice. Advertising song of male is a short, repetitive whistle, "wheeeeo" or "t-wheeeeo", given from ground and low perches, mainly at dusk and dawn. Flight call is a soft "tuk, tuk, tuk"; also gives a rolling "quaqrrr", usually from a perch.

Habitat. Prefers arid scrubland with scattered trees and bushes, dry open grassland and edges of deciduous woodland. Also near roads through dry deciduous forest, and in brushy mesquite woodland, thickets of second-growth mesquite, fallow farmland, wet pastures and damp grassy meadows. Recorded from sea-level to 775 m.

Food and Feeding. Feeds on moths, grasshoppers and beetles. Forages low over vegetation.

Breeding. Poorly known. Breeding commences at start of rains, which often highly irregular; season possibly Dec-Mar. Possibly double-brooded during prolonged rains, but may not breed at all in dry years. Nest-site often in small clearing in fairly dense vegetation, along edge of thicket or beneath tree; no nest, eggs laid on leaf litter on ground. Clutch 1-2 eggs, elliptical, pinkish-buff, heavily speckled and scrawled brown, reddish-brown and grey; chick not described.

Movements. Poorly understood. May be partially nomadic, moving seasonally with rains. No other information available.

Status and Conservation. Not globally threatened. Restricted-range species: present in Tumbesian Region EBA and Marañón Valley EBA. Range restricted to arid, coastal lowlands of W Ecuador and lowlands and hills at foot of W slope of Andes in NW Peru. In Ecuador, apparently locally common in suitable habitat, e.g. common and widespread on Santa Elena Peninsula; possibly increasing in some areas as a result of deforestation; present in Machalilla National Park (W Ecuador).

Bibliography. Best & Kessler (1995), Best *et al.* (1996), Chapman (1923), Meyer de Schauensee (1982), Parker, Parker & Plenge (1982), Parker, Schulenberg *et al.* (1995), Robbins *et al.* (1994), Schwartz (1968), Stattersfield *et al.* (1998), Stotz *et al.* (1996).

43. Cayenne Nightjar *Caprimulgus maculosus*

French: Engoulevent de Guyane

Spanish: Chotacabras Guayanés

German: Cayennenachtschwalbe

Taxonomy. *Nyctipolus maculosus* Todd, 1920, Tamanor, French Guiana. Monotypic.

Distribution. French Guiana.

Descriptive notes. 22.5 cm. Known only from type specimen, a male. Upperparts greyish-brown, broadly streaked blackish-brown on crown and nape; narrow, indistinct tawny nuchal collar; wing-coverts greyish-brown heavily spotted buff; scapulars blackish-brown, broadly edged buff; large white patch on either side of lower throat; underparts buff, heavily barred brown. Small white spot on four outermost primaries and broad white tips to three outermost tail feathers. Iris possibly dark brown, bill blackish, legs and feet dark brown. Paler, less black than *C. nigrescens*, with different pattern on scapulars. Immature plumages

not described. Voice. Unknown.

Habitat. Probably a forest species, inhabiting clearings, open areas and riversides; type specimen was taken in an area of such habitat, near lower reaches of a boulder-strewn river.

Food and Feeding. Presumably feeds on insects, but neither food nor foraging methods known.

Breeding. No information.

Movements. Unknown.

Status and Conservation. Not globally threatened. Data-deficient. Almost certainly merits treatment as a restricted-range species. True status unclear, but available evidence suggests species unlikely to be common, and might well be threatened. Known only from type specimen, taken Apr 1917 at Saut Tamanor on Fleuve Mana, c. 10 km above its confluence with R Cockioco, in French Guiana. Identity of a possible female caught at Saül airstrip, also in French Guiana, in Sept 1982 remains unconfirmed.

Bibliography. Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Ingels (1988), Meyer de Schauensee (1982), Olrog (1968), Stotz *et al.* (1996), Todd (1920), Tostain *et al.* (1992), Wege & Long (1995).

44. Blackish Nightjar *Caprimulgus nigrescens*

French: Engoulevent noirâtre

German: Trauernachtschwalbe

Spanish: Chotacabras Negruzco

Taxonomy. *Caprimulgus nigrescens* Cabanis, 1848, lower Essequibo River, Guyana. Forms superspecies with *C. whitelyi*. Monotypic.

Distribution. E Colombia and E Ecuador E through the Guianas and N Brazil, S to N & E Bolivia.

Descriptive notes. 19.5-21.5 cm; male 32-42 g, female 32-50 g. Sexually dimorphic. Upperparts blackish, heavily mottled tawny, cinnamon, buff and greyish-white, no nuchal collar; wing-coverts blackish, speckled and spotted buff, tawny, cinnamon and greyish-white; scapulars blackish-brown spotted tawny, often edged buff; small white patch on either side of lower throat; underparts dark brown, barred and spotted buff, buffish-white, tawny and cinnamon, becoming buffish barred brown on lower belly and flanks. Male has small white spot on second, third and fourth outermost primaries, and white tips to second

and third outermost tail feathers, occasionally also on inner web of outermost and outer web of fourth outermost; female lacks white markings on wings and tail. Iris dark brown, bill blackish, legs and feet dark brown. Slightly smaller than *C. whitelyi*, which occurs at higher altitudes in Pantepui of E Venezuela; present species has smaller white throat patch and bold white spots on tertials and inner wing-coverts, and more marked scapular pattern. Smaller and darker than *C. longirostris*, and lacks the broad tawny nuchal collar; different wing and tail markings. Immature

similar to adult but often slightly paler. Voice. Song of male is a soft, purring "pru.r.r.r." or "qu.r.r.r.t", given from rocks or other perches throughout night. Alarm calls are short, sharp "pink" or "prek" notes; gives guttural hissing sounds during threat, defence and distraction displays.

Habitat. Mainly sparsely vegetated, open stony country with granite outcrops, and rocky places in and along rivers; also rainforest, second growth, and open savanna with scattered bushes. Away from rocks, frequently found near tracks, in clearings and on recently burnt ground. Recorded from 100 m to 1100 m.

Food and Feeding. Feeds on moths, beetles and other insects. Forages over rocky outcrops and above tree canopy.

Breeding. Breeds possibly May-Aug in Guyana, Feb-Mar and Aug-Nov in Surinam (coinciding with dry season, though eggs found in all months except May and Dec), Sept-Oct in Bolivia, and Aug-Nov in W Brazil; no data from other regions. Normally double-brooded. Nest-site often close to vegetation in clearing or burnt area, alongside forest road, track or river, on granite outcrop or on exposed rock on river island; no nest, egg laid on bare ground, sandy soil or leaf litter, or in shallow depression up to 20-30 mm deep on granite rock. Clutch 1 egg, elliptical, slightly glossy, creamy-buff, pinkish-buff or reddish-brown, spotted and blotched brown and grey; replacement may be laid if clutch unsuccessful; incubation by both adults, period possibly c. 17 days; adults threatened at nest-site perform injury-feigning distraction display on ground; chick semi-precocial, covered in pale greyish down, fledges after c. 14 days and leaves nesting area within 16-18 days.

Movements. None recorded. Sedentary.

Status and Conservation. Not globally threatened. Abundant in suitable habitat throughout Amazon basin. Very common in some regions of Colombia such as Guainía and Vaupés, especially in areas of savanna woodland interspersed with cerros and rocky outcrops; widely distributed and common in Surinam and Guyana. Present in several protected areas, e.g. Amacayacu National Park (Colombia), Imataca Forest Reserve (Venezuela) and Voltzberg-Raleigh Falls Reserve (Surinam). Eggs and young often at risk from extreme temperatures or precipitation, especially those at nest-sites on granite surfaces, and potential predators include various mammals, birds and reptiles.

Bibliography. Blake (1950b), Friedmann (1948), Gilliard (1941), Haverschmidt & Mees (1994), Hilty & Brown (1986), Ingels (1988), Ingels & Ribot (1982, 1983), Ingels *et al.* (1984), Meyer de Schauensee & Phelps (1978), Parker *et al.* (1982), Remsen & Traylor (1989), Roth (1985), Sargeant (1994), Schubart *et al.* (1965), Sick (1993, 1997), Snyder (1966), Stotz *et al.* (1996), Tostain *et al.* (1992), Willard *et al.* (1991).

45. Roraiman Nightjar *Caprimulgus whitelyi*

French: Engoulevent du Roraima

Spanish: Chotacabras del Roraima

German: Roraimanachtschwalbe

Taxonomy. *Antrostomus whitelyi* Salvin, 1885, Mt Roraima, Venezuela.

Forms superspecies with *C. nigrescens*. Monotypic.

Distribution. Pantepui of SE Venezuela, and possibly also adjacent areas of Guyana and N Brazil. Known only from Cerros Roraima, Ptari-tepui, Jaua, Urutaní and Duida.

Descriptive notes. 21 cm; male 30-40 g, female 45-48 g. Sexually dimorphic. Upperparts blackish, spotted cinnamon, buff, greyish-white and tawny, no nuchal collar; wing-coverts blackish, spotted cinnamon, tawny and buff, no obvious scapular pattern; fairly large white patch on throat, rest of underparts dark brown, barred buff or buffish-white, becoming buff barred brown on belly. Male has thin white bar on three outermost primaries and large white spot on tips of inner webs of second and third outermost tail feathers; female has thin tawny bars on outer primaries and smaller white tail spots. Iris dark brown, bill blackish, legs and

feet dark brown. Slightly larger than *C. nigrescens*, with larger white throat patch, and white spots on tertials and inner wing-coverts; male of present species also differs in having white bars, not spots, on outer primaries and white tips only across inner webs of second and third outermost tail feathers. Smaller and generally darker than *C. longirostris* without the broad tawny nuchal collar of that species, and with different wing and tail markings. Immature plumages not described. Voice. Unknown.

Habitat. Apparently confined to humid, forested slopes and summits of tepuis (tabletop mountains), typically in open areas and clearings with scattered, dense vegetation. Recorded between 1280 m and 1800 m.

Food and Feeding. Probably feeds on insects. Foraging methods not described.

Breeding. No information.

Movements. None recorded. Sedentary.

Status and Conservation. Not globally threatened. Restricted-range species: present in Tepuis EBA. Currently considered Near-threatened. Probably not very common within its restricted and remote range, but poorly known.

Bibliography. Chapman (1931), Dickerman & Phelps (1982), Ingels (1988), Mayr & Phelps (1967), Meyer de Schauensee (1982), Meyer de Schauensee & Phelps (1978), Olrog (1968), Phelps (1938), Sick (1993, 1997), Stattersfield *et al.* (1998), Stotz *et al.* (1996).

46. Pygmy Nightjar *Caprimulgus hirundinaceus*

French: Engoulevent pygmée

German: Spixnachtschwalbe

Spanish: Chotacabras Pigmeo

Taxonomy. *Caprimulgus hirundinaceus* Spix, 1825, River Solimões; error = Feira de Sant'Anna, Bahia, Brazil.

Three subspecies recognized.

Subspecies and Distribution.

C. h. cearae (Cory, 1917) - NE Brazil (N Ceará to extreme N Bahia).

C. h. hirundinaceus Spix, 1825 - NE Brazil (S Piauí to Bahia and Alagoas).

C. h. vielliardi Ribon, 1995 - E Brazil (Colatina, Espírito Santo).

Descriptive notes. 16-20 cm. Sexually dimorphic. Upperparts and wing-coverts greyish-brown, densely speckled greyish-white or tawny and buff; no scapular pattern and no nuchal collar or an indistinct buff collar; thin whitish supercilium and indistinct buff submoustachial stripe; large white patch on throat with broad cinnamon-buff band below; underparts brown, densely spotted and barred

female lacking white on wings and generally also on tail. *Chordeiles pusillus* is usually browner and more variable in colour with a smaller white throat patch and whiter underparts; male has more defined white wing band, buffish-white trailing edge to inner wing and white tips to inner webs of second, third and fourth outer tail feathers; female has thinner white wing bands, duller trailing edge to inner wing and smaller white tips to tail feathers. Immature of present species paler than

pale buff and greyish-white, becoming buff barred brown on belly and flanks. Male has white spot on four outermost primaries and white tips to two outermost tail feathers (inner web only on outermost); female has smaller wing spots and lacks white on tail. Iris dark brown, bill blackish-brown, legs and feet blackish-brown. Somewhat similar to *C. parvulus*, which is browner and more variegated with blackish-brown scapulars broadly edged buff, broad but indistinct nuchal collar, no supercilium and a large white throat patch; male has larger white wing spots and white tips to all but central pair of tail feathers,

adult, often with strong cinnamon wash; primaries with broad buff tips. Races vary clinally in coloration: *cearae* paler, with less barring on underparts, which are sometimes plain, and larger white wing spots in male; *vielliardi* darker, with longer wings, and smaller white wing spots in male. VOICE. Song of male is a short, whistled "wheeo" or "wheo", often preceded by 3-4 rapid "wha" notes. Flight calls also "wha, wha, wha" notes.

Habitat. Typically woodland, but also cleared areas; newly described race *vielliardi* inhabits rocky areas.

Food and Feeding. Probably feeds on insects. Forages in open country but methods not described. **Breeding.** Poorly documented. Nest-sites recorded beside dirt roads and tracks.

Movements. None documented. All races possibly sedentary.

Status and Conservation. Not globally threatened. Restricted-range species: present in North-east Brazilian Caatinga EBA. Currently considered Near-threatened. Previously considered endemic to caatinga of NE Brazil but a disjunct population in Colatina, Espírito Santo, first recorded in 1980's, has now been described, suggesting further populations may possibly await discovery. Few data available from most of range, but not rare in Capiwara National Park, SE Piauí; also present in Parque Estadual da Pedra Talhada, 160 km W of Maceió, in Alagoas.

PLATE 31

inches 5
cm 13

47. Brown Nightjar *Caprimulgus binotatus*

French: Engoulevent à deux taches **Spanish:** Chotacabras Bimaculado
German: Bootschwanz-Nachtschwalbe
Other common names: Dusky Nightjar(!)

Taxonomy. *Caprimulgus binotatus* Bonaparte, 1850. Borneo; error = Ashanti, Dabocrom, Ghana. Current treatment requires further study; formerly split off in monotypic genus *Veles*, and notable morphological peculiarities suggest that this may indeed be appropriate (see page 306). Monotypic.
Distribution. Liberia discontinuously E to C Zaire, where restricted to rainforest zone.

Descriptive notes. 21–23 cm; 1 unsexed 63 g. Sexes similar, but female somewhat paler above. Upperparts and wing-coverts dark brown, densely mottled and flecked tawny and chestnut-brown, no nuchal collar; small white spot on either side of lower throat; rictal bristles short and weak; underparts dark brown, mottled and barred tawny and chestnut-brown; outer primaries curved, tail stiff and held in inverted V when bird at rest; both sexes lack white markings on wings and tail. Iris brown, bill blackish, legs and feet dark brown. Immature similar to adult, but scapulars and inner coverts pale greyish-buff, spotted dark brown.

VOICE. Song of male is a repetitive series of “twoh” or “kliou” notes, given from perches or in flight.
Habitat. Mainly lowland primary rainforest, often with open canopy and thick understorey. Found in semi-evergreen or semi-deciduous forest. In SW Central African Republic, also recorded at edges of *Raphia* swamps in dense rainforest.

Food and Feeding. Feeds on insects. Forages by making flycatching sallies from perches, usually hawking close to forest canopy.

Breeding. Poorly known. Possibly breeds Jan-Mar in Liberia, Feb-Mar in Central African Republic, and May-Jun in Cameroon. Possibly territorial. Nest-site possibly above ground, e.g. on arched leaves of *Raphia* palms.

Movements. None recorded. Sedentary.

Status and Conservation. Not globally threatened. Possibly eligible for listing as threatened species. Probably uncommon to rare throughout range and generally confined to lowland rainforest; possibly under-recorded. Rare in Ghana, though some habitat protected, e.g. a few records since 1970's from Ahanta Forest Reserve; local and rare in Cameroon, though present in protected areas such as Korup National Park; possibly not uncommon locally in extreme N Congo, with 7 singing males located in Nouabalé-Ndoki National Park in 1997, territories 500–1000 m apart in suitable habitat; probably not common in Zaire. Loss of habitat through deforestation main potential threat.

Bibliography. Bannerman (1953), Brosset & Éard (1986), Carroll (1988), Carroll & Fry (1987), Christy & Clarke (1994), Colston & Curry-Lindahl (1986), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Dowsett-Lemaire & Dowsett (1998a, 1998b), Dutton & Branscombe (1990), Evans (1993), Fry (1988b), Fry *et al.* (1988), Gatter (1997), Grimes (1987), Lippens & Wille (1976), Louette (1981, 1990b, 1990c), Mackworth-Præd & Grant (1970), Rodewald *et al.* (1994), Snow (1978).

48. Red-necked Nightjar *Caprimulgus ruficollis*

French: Engoulevent à collier roux **Spanish:** Chotacabras Cuellirrojo
German: Rothals-Ziegenmelker

Taxonomy. *Caprimulgus ruficollis* Temminck, 1820. Algeciras, Spain. Two subspecies recognized.

Subspecies and Distribution.

C. r. ruficollis Temminck, 1820 - Spain, Portugal and N Morocco.

C. r. desertorum Erlanger, 1899 - NE Morocco, N Algeria (S to Great Atlas Mts) and N Tunisia.

Winters mainly in W Africa.

Descriptive notes. 30–32 cm; male 70–102 g, female 81–86 g, unsexed 60–119 g. Sexually dimorphic. Upperparts greyish-brown streaked blackish-brown; broad buff or tawny-buff nuchal collar; wing-coverts greyish-brown boldly spotted buff; scapulars blackish-brown, broadly bordered buff on outer webs; prominent white or buffish-white submoustachial stripe and white throat patch; underparts greyish-brown, speckled greyish-white barred brown, becoming buff barred brown on belly and flanks. Male has large white spot on three outermost primaries (usually inner webs only) and broad white tips to two outermost tail feathers.

female has smaller wing and tail spots. Iris dark brown, bill blackish-brown, legs and feet greyish-brown. Larger and generally paler and less brown than *C. europæus*, which shows distinct buffish line across wing-coverts and white primary patch closer to wingtip. Immature similar to adult but paler, with buffish wing and tail markings. Race *desertorum* is paler, more sandy-buff, often tinged rufous, with narrower streaking on crown and broader nuchal collar. Voice. Song of male is a repetitive series of loud “cut-ok” notes, often preceded by rapid “quot” calls, chuckles or gurgles; sings from perches throughout night. Flight call is a single or double-noted “cutow”; incubating adult may give accelerating, knocking notes. All birds make guttural hissing sounds during threat/defence displays.

Habitat. Typically lowlands and hillsides, with scattered vegetation and bare ground, in pine woodland, coastal forest, eucalyptus or olive plantations, vineyards, open scrubland with cork oak (*Quercus suber*), prickly pear (*Opuntia*) or scattered trees, and dense thickets of broom, gorse, bramble, tree

heath (*Erica arborea*) or pistachio (*Pistacea lentiscus*). Also semi-deserts, and in Tunisia cactus plantations. Tends to avoid treeless country and sand dunes. Recorded from sea-level to 1500 m.
Food and Feeding. Diet includes moths, moth larvae, locusts and locust nymphs, mosquitoes, flies, grasshoppers, beetles and caterpillars. Also ingests items such as small seeds, earth and grains of sand, possibly by accident. Forages in open habitats, sometimes high up and usually alone. Occasionally forages on ground.

Breeding. Breeds early May to late Aug in Spain and Portugal, and mid-May to Aug in C Morocco, Algeria and Tunisia. Possibly double-brooded. Probably monogamous; territorial; usually solitary, but in Tunisia nests sometimes in loose groups 2–20 m apart. Nest-site in open, beneath or among low bushes, beside fallen log or branch or under tree, in Tunisia also in cactus plantation, in S Portugal also among coastal driftwood on sandbank; no nest, eggs laid on ground, usually on leaf litter or pine needles. Clutch usually 1–2 eggs, elliptical, glossy white or creamy-white, marbled and blotched grey and brown; incubation usually by female, at least during day, period generally 14–19 days, eggs hatching asynchronously; chick semi-precocial, covered in brownish-buff down; female threatened at nest-site may perform injury-feigning distraction display; chicks make first flights at c. 16–18 days and become independent after 4–5 weeks.

Movements. Migratory. Nominate race leaves breeding grounds by late Oct or Nov. Regular autumn migrant through Gibraltar, along coast of Morocco and across NW Africa (e.g. W & C Mauritania Oct–Nov). Some may winter in Morocco (e.g. Chichaoua Dec–Jan) but usually winters farther S in W Africa, though exact range unclear. Recorded N Senegal late Nov and Jan, and C & S Mali Oct–Mar, where common and widespread. In spring, return movements on broad front (Mar to early May) across Mauritania, Western Sahara, Morocco and W Algeria, returning to breeding grounds from late Apr to May. Race *desertorum* migratory and partially sedentary; movements and wintering range probably similar to nominate race. Recorded N Senegal late Nov, E Gambia Nov, and Mali, Ivory Coast and N Ghana (Gambaga) Mar. Winter records (race unknown) also from Liberia in Dec and Ivory Coast in Nov and Jan. Vagrants recorded in Britain, Denmark, Ibiza, Sicily, Malta, Libya and Madeira and possibly Yugoslavia, Turkey and Canary Is; single record from France during present century, a bird found dead at Bouches-du-Rhône in Jun 1997.

Status and Conservation. Not globally threatened. Reasonably common in Spain with 100,000–131,000 breeding pairs, range and population levels apparently not declining; locally common in Portugal with 1000–10,000 pairs, but declining in Algarve region due to habitat loss and disturbance from tourist industry; has also bred in S France, but only single (non-breeding) record from 20th century. Sparingly distributed in Morocco, where apparently declining; sparsely distributed but locally fairly common in Tunisia; possibly not widely distributed in Algeria. Loss of habitat to urbanization or agriculture probably biggest threat; nests in cultivated areas often at risk from agricultural activities; predation poorly documented, but in S Spain eggs and chicks may be taken by lizards (*Lacerta lepida*). On wintering grounds, uncommon in Morocco (Chichaoua region); probably not common in coastal areas of W Mauritania; uncommon in N Senegal; 9 road casualties recorded in Gambia since 1990, suggesting species previously overlooked there; widely distributed and reasonably common in Mali; few records Ivory Coast and Ghana; probably under-recorded. Increasing road traffic in all regions, responsible for some mortality.

Bibliography. Aragón (1996, 1997a), Aragón *et al.* (1998), Asensio *et al.* (1994), Badan & Kowalski (1998), Bannerman (1953), Barlow & Gale (1999), Barlow *et al.* (1997), Beven (1973), Christensen (1996), Copete & Gustamante (1992), Cowles (1967), Cramp (1985), Cuadrado & Domínguez (1996), Díaz, Asensio & Tellería (1996), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Eitchépar & Hue (1964), Finlayson & Tomlinson (1993), Forero, Tella & Gajon (1997), Forero, Tella & García (1995), Fry *et al.* (1988), Fuller (1995), Gargallo (1994), Gatter (1997), Grimes (1987), Hagemeijer & Blair (1997), Ledant *et al.* (1981), Mackworth-Præd & Grant (1970), Purroy (1997), Salewski (1997), Snow & Perrins (1998), Soares (1973), Thomsen & Jacobsen (1979), Tomás (1991).

49. Jungle Nightjar *Caprimulgus indicus*

French: Engoulevent jotaka **German:** Dschungelnachtschwalbe **Spanish:** Chotacabras de Jungla
Other common names: Indian Jungle Nightjar, Grey/Japanese Nightjar, (Ceylon) Highland Nightjar

Taxonomy. *Caprimulgus indicus* Latham, 1790. India.

Sometimes reckoned to be an eastern counterpart of *C. europæus*. Five subspecies recognized.

Subspecies and Distribution.

C. i. hazarae Whistler & Kinneir, 1935 - NE Pakistan E across Himalayas to NE India, Bangladesh and S China (Yunnan). S through Myanmar and Malay Peninsula.

C. i. indicus Latham, 1790 - India S of Himalayas (absent W Rajasthan and Kachchh).

C. i. kelaarti Blyth, 1852 - Sri Lanka.

C. i. jotaka Temminck & Schlegel, 1847 - SE Siberia, E. C & S China, Japan and Korea; winters from S China to Greater Sundas and Philippines.

C. i. phalaena Hartlaub & Finsch, 1872 - Palau Is.

Descriptive notes. 28–32 cm; male 60–108 g, female 65–92 g. Sexually dimorphic. Upperparts greyish-brown streaked blackish-brown, broadly so on crown; indistinct pale buff or tawny-buff nuchal collar; lesser coverts brown, speckled greyish-white, buff or tawny; rest of wing-coverts greyish-brown, boldly spotted greyish-white, pale buff or pale tawny with spots distinctly smudged or vermiculated brown; scapulars blackish-brown, broadly edged greyish-white vermiculated brown; buffish-white submoustachial stripe; large white patch on either side of lower throat; underparts greyish-brown, finely barred greyish-

brown or pale buff, becoming buff barred brown on belly and flanks. Male has four outer primaries with large white spot (inner web only on outermost one), and white tips to all but central pair of tail feathers; female has tawny wing spots and brownish-white or brownish-buff tips to tail feathers. Iris dark brown, bill brownish or blackish, legs and feet brownish. Larger than *C. asiaticus*, which has broad buff or tawny nuchal collar and much broader white tips to outermost tail feathers in male. Differs from both *C. macrurus* and *C. atripennis* by bold spotting on wing-coverts, and less broad white tips to two outermost tail feathers in male; from *C. manillensis* also by bold spotting on wing-

coverts, and that species shows buffish line across forewing. Larger than *C. affinis*, in which male usually has two outermost tail feathers entirely white. Immature similar to adult female. Races vary clinally in size and coloration: *hazarae* and *jotaka* larger and darker; *kelaarti* smaller and greyer, with more white markings; and *phalaena* smaller and perhaps more rufous. VOICE. Song of male is a rapid series of loud "tuk, tuk, tuk, tuk" notes, also a repetitive "tukoo, tukoo, tukoo" that occasionally ends with a hollow "wowowowow"; sings from perches, from ground and in flight. Calls include rapid sets of deep "quor" or soft "you" sounds. In Sri Lanka, flight call of male noted as "hóó, hóó, hóó hóóter".

Habitat. Mainly forest, woods and wooded country, in open woodland, deciduous, pine and mixed bamboo forest, glades and thick brush jungle; also open scrubland, farmland and cultivation, mandarin orange (*Citrus reticulata*) orchards and teak plantations. In Himalayas, also in sparsely vegetated ravines and on jungle-clad hillsides. In Sri Lanka, also occurs in stony fields. Wintering and passage birds have been recorded in large cities. Recorded from sea-level to 3300 m.

Food and Feeding. Feeds on moths, beetles, bugs, flying ants, cicadas, grasshoppers, locusts and small wasps. Foraging flight extremely agile and buoyant. Hunts close to ground, or high up over trees. Also feeds on insects attracted to artificial lights.

Breeding. Breeds late May to early Aug in Japan, Mar-Jun (mainly Apr-May) in Himalayas, late Apr to Jul in Pakistan, Feb-May (mainly Mar-Apr) in India, late Feb to Aug in S India, and Feb-Jul in Sri Lanka. Nest-site near or on rock, beneath vegetation, in thicket, on stony slope or in ravine; no nest, eggs laid on leaf litter, bare ground, or ashes following bush fires. Clutch 1-2 eggs, elliptical, creamy-white, spotted and marbled grey, brown and amber; incubation generally by female, male taking turns at dusk and dawn, period usually 16-19 days; chick covered in brown and buff down, fledges at c. 17 days.

Movements. Poorly understood. Throughout much of range from India E to S China, populations largely sedentary or locally migratory, some movements possibly altitudinal only. Races *kelaarti* in Sri Lanka and *phalaena* on Palau is probably sedentary. Race *jotaka* highly migratory: leaves breeding grounds Sept-Nov, moves S through E China, and possibly across South China Sea, to winter from S China, Indochina and Malaysia to Sumatra, Java, Borneo and Philippines. Japanese population possibly moves across Sea of Japan rather than East China Sea. Return migration probably Mar-May. Vagrants, possibly of migratory race *jotaka*, recorded in N Moluccas (Halmahera Is.), NW New Guinea (Manokwari, Irian Jaya) and Aleutian Is (Buldir Is).

Status and Conservation. Not globally threatened. Locally common summer visitor in NE Pakistan; common in India, where resident in many regions, locally migratory in others; locally common in Sri Lanka (perhaps commoner in E); fairly widespread throughout much of China; local but not uncommon summer visitor to Japanese islands of Kyushu, Shikoku, Honshu and Hokkaido; locally common to abundant in E and SE parts of Russia; fairly common passage migrant and winter visitor throughout Malaysia; rare winter visitor in Philippines; widespread winter visitor in Borneo, possibly more regular at higher altitudes. Adaptable, often occupying areas of deforestation and cultivation.

Bibliography. (1990, 1999), Whistler & Kinnear (1935), White & Bruce (1986), Zhao Zhengjie (1995).

50. European Nightjar

Caprimulgus europaeus

French: Engoulevent d'Europe German: Ziegenmelker Spanish: Chotacabras Europeo
Other common names: (Eurasian) Nightjar, Common Nightjar

Taxonomy. *Caprimulgus europaeus* Linnaeus, 1758, Sweden.

Forms superspecies with *C. fraenatus* and *C. rufigena*. Sometimes reckoned to be replaced to east by *C. indicus*. Much of geographical variation is clinal. Six subspecies recognized.

Subspecies and Distribution.

C. e. europaeus Linnaeus, 1758 - N & C Europe E through NC Asia (mainly S of c. 60° N) to L Baikal region.

C. e. meridionalis Hartert, 1896 - NW Africa and Iberia E through S Europe, Crimea, Caucasus and Ukraine to NW Iran and Caspian Sea.

C. e. sarudnyi Hartert, 1912 - Kazakhstan, from Caspian Sea E to Kyrgyzstan, Tarbagatai and Altai.

C. e. uniwini Hume, 1871 - Iraq and Iran E to W Tien Shan and Kashgaria, N to S Turkmenistan and Uzbekistan.

C. e. plumipes Przewalski, 1876 - NW China and W & NW Mongolia.

C. e. dementievi Stegmann, 1949 - NE Mongolia and S Transbaikalia.

Winters in sub-Saharan Africa.

markings. Iris dark brown, bill blackish, legs and feet brown or flesh-brown. Smaller and darker brown than *C. ruficollis*, with white spots on primaries closer to wingtip. Larger than *C. rufigena*, with nuchal collar far less distinct. Paler and generally larger than *C. fraenatus*, which is more heavily spotted, and has broad buff or tawny-buff nuchal collar. Immature similar to adult female. Racial variation is generally clinal, birds becoming smaller and paler to E through range, with white wing spots of males becoming larger. VOICE. Song of male is a distinctive, continuous churring that frequently changes to a lower pitch and back again. Sings from perches and occasionally from ground. Contact call of both sexes, usually given in flight, is a short "co-ic"; bubbling trills are

given by male during interactions with female. A wide variety of calls given by both sexes include "chunk", "chink", "chik", "dak", "chuk", "chek", "chek-ek", "chuk" or clucking notes; at nest-site adult grunts or gives gruff "wuk, wuk, wuk" or muffled "oak, oak" notes; female also gives loud quacks. All birds make guttural hissing sounds during threat/defence displays. Chick utters a variety of chirps and cheeps.

Habitat. Mainly dry, open country: lowland heaths with scattered trees and bushes, commons and moorland, forest and woodland (especially glades, clearings and edges), recently felled woodland and young forestry plantations. Also chalk downland, industrial waste tips, wooded or scrub-covered steppe, sparsely forested or stony hillsides, oak scrubland, dense coppices, shingle, sand dunes, semi-deserts and deserts. Tends not to breed in urban areas, mountains, steppes, treeless plains, dense forest interior, mature plantations, cultivation and tall grassland, but not infrequently forages over such areas as farmland, gardens, reedbeds and wet habitats (e.g. marshes). On wintering grounds in wooded country, dry coastal acacia steppe, forest clearings, open sandy country and highlands. Recorded from sea-level to 2800 m on breeding grounds, up to 5000 m during winter.

Food and Feeding. Diet includes moths, beetles, mantises, mayflies, dragonflies, Orthoptera, cockroaches, bugs, Hymenoptera, antlions, lacewings, caddisflies and flies. Occasionally takes butterflies and flightless glow-worms, and also feeds on spiders and mites, latter probably taken with other prey items. Grit and small stones are also ingested and vegetable matter is probably taken accidentally. Foraging flight is agile and buoyant. Hunts over open country, in clearings, along woodland edges and borders, in woodland glades and rides, in gardens and orchards, over wetlands, in meadows and farmland, around grazing animals, and over stagnant ponds. Usually feeds solitarily, but loose feeding flocks sometimes occur. Also feeds on insects at artificial lights. May forage diurnally on overcast days. Also makes short flycatching sallies from ground or low perches, and hovers close to vegetation to take food from foliage. Occasionally hovers and swoops down after prey. Rarely feeds on ground, but does so by darting forward to take prey. Drinks in flight.

Breeding. Breeds late May to Aug, occasionally Apr-Jul in some regions; breeding often influenced by lunar phase. Single-brooded or double-brooded. Generally monogamous; territorial. Nest-site in open, beneath tree, bush or shrub, within upturned tree roots or among vegetation, occasionally inside mature plantation; sometimes used for several successive years; no nest, eggs laid on ground, on leaf litter, pine needles or bare soil. Clutch usually 1-2 eggs, elliptical, smooth and fairly glossy, whitish, greyish-white or cream, spotted and blotched yellow-brown, dark brown and grey or densely scrawled brown and grey, rarely unmarked, laid at intervals of 36-48 hours; incubation begins with first egg, mainly by female, period 17-21 days, eggs hatching asynchronously; chick semi-precocial, covered in dark brown and creamy-buff down, brooded by female for 10-16 days, then by male if female lays second clutch; female threatened at nest-site performs injury-feigning distraction display on ground, from exposed perch or in flight; young fledge at 16-17 days and become independent at c. 32 days. If two broods, female leaves first brood when chicks 10-16 days old; male then generally tends first brood and helps with second.

Movements. Highly migratory. Nominate race leaves breeding grounds late Jul to Nov (mainly late Aug to Oct), W populations moving S on broad front across Europe, Mediterranean and N Africa, E populations moving SW on broad front through Middle East (mid-Aug to early Dec) and E Africa. Winters mainly in E & S Africa, although small numbers may winter in W Africa. In spring, returning birds move N or NE, Mar-Jun, generally returning to breeding grounds Apr-May. Race *meridionalis* moves S on broad front across Mediterranean, N parts of Middle East and N Africa, and winters mainly in S and perhaps C Africa, though small numbers may winter in W Africa. Return movements probably at same time as nominate race. Race *sarudnyi* possibly winters mainly in E & SE Africa. In spring, moves NE through Arabian Peninsula, perhaps late Feb to May. Race *unwini* leaves breeding grounds possibly Aug-Sept and moves SE on broad front across Middle East; winters mainly in E & SE Africa, although small numbers occasionally overwinter in Israel, Pakistan and possibly NW India. Return route in spring apparently farther N. After breeding, race *plumipes* moves SW on broad front and winters mainly in SE Africa. Race *dementievi* probably also winters in E & SE Africa. Vagrants recorded in Iceland, Faeroes, Azores, Madeira, Canary Is and Seychelles.

Status and Conservation. Not globally threatened. Locally common to very common in suitable habitat throughout breeding range, though decreasing in numbers and/or range in many regions, especially in NW Europe. Total European breeding population estimated at 290,000-830,000 pairs, most in Russia (up to 500,000 pairs), Spain (up to 112,000 pairs) and Belarus (up to 60,000 pairs). Throughout range, breeding densities vary from 0.1 pair per km² to 19.4 pairs per km²; territory size variable, 1.5-31.9 ha. In Europe, major declines noted in late 19th century and these have continued through current century, most notably since 1970's, in Britain and Ireland, France, Belgium, Luxembourg, Netherlands, Denmark, Sweden, Finland, Czech Republic, Austria, Switzerland, Spain, Italy, Albania, Romania, Croatia, Bulgaria, Ukraine and Moldova; contraction of range also recorded in Andorra, Portugal and possibly Denmark; numbers also declining in Norway, Germany, Estonia, Latvia and Greece. Decreases probably due to reduction of insect availability resulting from pesticide use, increasing road traffic, disturbance at breeding sites, and loss or degradation of habitat, although in some countries, e.g. Britain, creation of habitat through commercial forestry has seen increase in numbers in recent years, though habitats not permanent and stability of higher population levels not guaranteed. Numerous predators, especially of eggs and chicks, include crows (*Corvus*), Magpies (*Pica pica*), Jays (*Garrulus glandarius*), owls (Strigidae), Sooty Falcon (*Falco coloratus*), hedgehogs (*Erinaceus europaeus*), weasels (*Mustela nivalis*) and domestic dogs. In Pakistan, a widely distributed and common breeding bird and passage migrant, a few birds possibly overwintering occasionally. On African wintering grounds, often common in SW Mauritania, probably under-recorded in NW Senegal, decreased in Gambia since early 20th century, rare in Ghana, fairly common in E Nigeria and S Cameroon, but very few records from other W African countries. Not uncommon in much of SE African range from Kenya (passage migrant only) and Tanzania S to Natal, though fairly common locally in Mozambique; widely distributed, especially in SE low veld, but possibly not common in Zimbabwe; scarce in Zambia.

Bibliography. 51. Sombre Nightjar

Caprimulgus fraenatus

French: Engoulevent sombre **German:** Zügelnachtswalbe **Spanish:** Chotacabras Oscuro
Other common names: Dark Nightjar, Dusky Nightjar(!)

Taxonomy. *Caprimulgus fraenatus* Salvadori, 1884, Daimbi, Shoa.

Formerly considered conspecific with *C. rufigena*, and these two form superspecies with *C. europaeus*. In past, birds of Kenya occasionally separated as race *keniensis*, but probably not sufficiently distinct. Monotypic.

Distribution. Patchily from Ethiopia and NW Somalia S to NE Tanzania.

Descriptive notes. 25 cm; male 55-71 g, female 46-68 g. Sexually dimorphic. Upperparts dark brown, speckled greyish-white and streaked blackish-brown; broad buff or tawny-buff nuchal collar; wing-coverts dark brown, heavily spotted tawny and buff; scapulars irregularly marked blackish; white submoustachial stripe and white throat patch; underparts dark brown spotted buff, becoming buff barred brown on belly and flanks. Male has large white spot on four outermost primaries and broad white tips to two outermost tail feathers; female has pale buff wing spots and buff tips to tail. Iris dark brown, bill black, legs and feet

brown. More heavily spotted on wing-coverts and breast than *C. rufigena*, which is greyer and paler with streaked upperparts. Generally smaller than *C. europaeus*, which is paler with indistinct or no nuchal collar and shows buff line across wing-coverts; male of that species has smaller white wing and tail spots, female lacking white. Immature of present species similar to adult but browner and paler. Voice. Song of male is a low, evenly pitched, churr, occasionally interrupted by "kik-wow", "a-whoop" or liquid "kow" notes; sings from perches and possibly also from ground. Flight call is a liquid "quik" note; utters a throaty hiss during threat/defence displays.

Habitat. Typically open, stony bushland and scrubland; also grassland, sage bush, *Dodonaea* scrub and eucalyptus plantations. Recorded from sea-level to 3200 m.

Food and Feeding. Feeds on moths, grasshoppers, bugs and beetles. Forages by hawking for insects.

Breeding. Breeds May to perhaps Jul in NW Somalia, Feb-May and Nov in W Kenya, Jan-Mar and Sept-Nov in Ethiopia, C & S Kenya and NE Tanzania, and possibly Jun (though status unclear and breeding not proven) in SW Somalia and coastal Kenya. Probably monogamous. No nest, eggs laid on bare earth or sandy ground, usually among grass, often partly sheltered by shrubs or bushes. Clutch 1-2 eggs, elliptical or elliptical-ovate, pinkish-white, pinkish-buff or possibly glossy white, faintly spotted and blotched brown, lilac and grey, markings denser around blunt end; incubation usually by female, at least during day; female threatened at nest-site may give injury-feigning distraction display.

Movements. Generally sedentary, though locally migratory in parts of range. Small population occurs as breeding visitor (May-Oct) in NW Somalia and winters in Ethiopia. Outside normal breeding range, also recorded SW Somalia and N & E Kenya, and as a possible vagrant in Zaire (Ruwenzori), Burundi (Bujumbura) and S Tanzania (Njombe highlands).

Status and Conservation. Not globally threatened. Few data available; may be locally common in suitable habitat. Uncommon in extreme SE Sudan; not uncommon locally in NW Somalia; widespread and locally fairly common in W & S Kenya, where present in Tsavo West and Tsavo East National Parks; widely distributed and possibly fairly common in NE Tanzania.

Bibliography. Archer & Godman (1937-1961), Ash & Miskell (1983b, 1998), Britton (1980), Brown & Britton (1980), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Duckworth *et al.* (1992), Friedmann (1930), Fry *et al.* (1988), Hanmer (1996), Jackson & Slater (1938), Lack & Quicke (1978), Lewis & Pomeroy (1989), Louette (1988b), Mackworth-Praed & Grant (1957), Nikolaus (1987, 1989), Oyugi (1995), Short *et al.* (1990), Smith (1957), Snow (1978), Tilahun *et al.* (1996), Urban & Brown (1971), Zimmerman, D.A. *et al.* (1996).

52. Rufous-cheeked Nightjar

Caprimulgus rufigena

French: Engoulevent à joues rousses **Spanish:** Chotacabras Carirrojo
German: Rostwangen-Nachtschwalbe

Taxonomy. *Caprimulgus rufigena* A. Smith, 1845, Eastern Cape Province, South Africa.

Formerly considered conspecific with *C. fraenatus*, and these two form superspecies with *C. europaeus*. In past, birds of Angola occasionally separated as race *quanzae*, but probably not distinct from nominate. Two subspecies currently recognized.

Subspecies and Distribution.

C. r. damarensis Strickland, 1852 - coastal W Angola, Namibia (except coastal region), Botswana and NW South Africa.

C. r. rufigena A. Smith, 1845 - South Africa, Zimbabwe and S Zambia; possibly also S Mozambique and S Angola.

Winters mainly in Nigeria and Cameroon.

Descriptive notes. 23-24 cm; male 48-65 g, female 46-66 g. Sexually dimorphic. Upperparts greyish-brown streaked blackish-brown; narrow buff or tawny-buff nuchal collar; wing-coverts greyish-brown, spotted tawny and buff, with broad buff line along scapulars; white throat patch; underparts greyish-brown spotted buff, becoming buff barred brown on belly and flanks. Male has large white spot on four outermost primaries and white tips to two outermost tail feathers; female has smaller white wing spots, usually tinged tawny, and buff tips to two outermost tail feathers. Iris brown, bill blackish, legs and feet brownish-flesh. Generally smaller than *C. europaeus*, which has indistinct or no nuchal collar and shows buff line across wing-coverts, female lacking white on wings and tail. *C. fraenatus* is darker and more heavily spotted; male has broader white tips to two outermost tail feathers; female has larger pale buff wing spots and broader buff tips to two outermost tail feathers. Immature of present species similar to adult but paler. Race *damarensis* is paler and greyer with upperparts more thinly streaked. Voice. Song of male is a continuous, evenly pitched churr, often

commencing with "a-whoop" notes and ending with low-pitched "kow" calls. Sings from ground or perches, mainly at dusk and dawn. Flight and alarm calls consist of "chuk" notes.

Habitat. Mainly open wooded savanna, miombo woodland, woodland edges and clearings, semi-arid acacia scrubland and semi-deserts; also in plantations and on sparsely vegetated hillsides. Recorded from sea-level to 1600 m.

Food and Feeding. Feeds on moths, beetles and other insects. Foraging methods not fully documented, although large numbers of birds may congregate where food supply is plentiful.

Also feeds on insects attracted to artificial lights.

Breeding. Breeds Sept-Nov in Angola and Zambia, Sept-Jan in Botswana, and Sept-Dec in Zimbabwe and South Africa. Monogamous; territorial. Nest-site partially shaded or in open, in burnt area, dry woodland, or occasionally damp vleis, recently felled woodland or open agricultural country; no nest, eggs often laid on bare earth, tends to avoid dense leaf litter. Clutch 1-2 eggs, elliptical, glossy, whitish, buffish or pale pinkish-cream, faintly but densely spotted and blotched brown, grey and lilac, occasionally unmarked; incubation period generally 15-17 days, beginning with first egg; chick covered in greyish-white and rufous down, fledges within 18-20 days.

Movements. A breeding visitor to much of S & SW Africa, after which moves N to winter in WC Africa. Main wintering range apparently in Cameroon (Apr-Aug) and less commonly Nigeria (May-Aug). May also winter in W Congo basin. Occurs as passage migrant in Zimbabwe, Zaire (whole country on N migration, W parts only on S migration), N Zambia, N Angola, Congo and Gabon. Also recorded as probable vagrant in Central African Republic and W Sudan (Darfur).

Status and Conservation. Not globally threatened. Frequent to locally common in suitable habitat during breeding season. Few data available on population levels; in S Zambia, common in Choma region, possibly scarce at all other localities; widespread in Zimbabwe, mainly on high veld; widely distributed and fairly common in most regions in Botswana; widespread and fairly common in South Africa, though apparently absent from much of E coast and from Natal; absent from coastal areas of W Namibia. On wintering grounds, frequent but widely distributed in wooded country, especially in Cameroon; rare in Nigeria, where only occasionally recorded at 1-4 localities; local and rare in Darfur region of Sudan. Present in several protected areas, including Kafue National Park (S Zambia), Hwange National Park (SW Zimbabwe) and Etosha National Park (Namibia).

Bibliography. Bannerman (1953), Bates (1927), Benson *et al.* (1971), Cave & Macdonald (1955), Clancey (1966, 1996), Colebrook-Robjent (1979, 1984), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Elgood *et al.* (1994), Fry *et al.* (1988), Ginn *et al.* (1989), Harrison *et al.* (1997), Hockey *et al.* (1989), Jackson (1975, 1978, 1986), Lippens & Wille (1976), Louette (1981, 1990b), Mackworth-Praed & Grant (1957, 1962, 1970), Maclean (1993), Nikolaus (1987), Penry (1994), Pinto (1983), Snow (1978), Steyn (1996a, 1996b), Stresemann & Stresemann (1966), Tyler (1992).

53. Egyptian Nightjar

Caprimulgus aegyptius

French: Engoulevent du désert **German:** Pharaonenziegenmelker **Spanish:** Chotacabras Egipcio

Taxonomy. *Caprimulgus aegyptius* Lichtenstein, 1823, upper Egypt.

Asian populations (E of Syria) sometimes separated as race *arenicolor*, but variation is clinal, with birds increasing in size towards east. Two subspecies recognized.

Subspecies and Distribution.

C. a. saharae Erlanger, 1899 - C & EC Morocco, N (and occasionally S) Algeria, C Tunisia, probably NW Libya, and possibly E towards N Egypt; winters in W Sahel.

C. a. aegyptius Lichtenstein, 1823 - NE Egypt and N Arabian Peninsula, E to extreme CW China, NE Kazakhstan, Tajikistan, extreme W Pakistan and SE Iran; winters in E Sahel.

Descriptive notes. 24-26 cm; male 68-93 g, 1 female 70 g. Sexually dimorphic, though not greatly so. Upperparts sandy-grey or greyish-buff, lightly spotted blackish-brown; indistinct buffish nuchal collar; wing-coverts sandy-grey or greyish-buff, speckled and vermiculated brown and blackish brown and boldly spotted buff, no scapular pattern; buffish-white submoustachial stripe and white throat patch; underparts sandy-grey or greyish-buff, spotted buff and barred brown, becoming buff barred brown on belly and flanks. Both sexes generally lack white wing spots (although some show a small white spot towards wing

tip) but have white underwings. Male has narrow whitish tips to two outermost tail feathers; female has pale buffish tips. Iris dark brown, bill blackish or dark brown, legs and feet blackish, greyish or brownish. Larger than *C. maharattensis*, which has white wing spots; and male has broad white tips to two outermost tail feathers, female having narrow buffish-white tips. Immature of present species similar to adult but paler and plainer. Race *saharae* is sandier and slightly smaller. Voice. Song of male is a long series of purring "kowr" notes; sings from ground, mainly at dusk and dawn. Birds also utter short churrs, "tuk-l, tuk-l", "chuc, chuc", croaking "toc" and growling "owk" calls.

Habitat. Typically deserts and semi-deserts, often close to water; also arid plains of sand or clay with scattered scrub and tamarisks, and dry waste ground near water. In wintering area in Sudan, also found in long grass among trees. Race *saharae* breeds in deserts, desert-steppe, or sandy steppe with limestone outcrops, and winters in dry country with *Salsola*, *Artemisia* and tamarisks, or among rice fields.

Food and Feeding. Diet includes beetles, bugs, moths, crickets, grasshoppers, ants, termites and mosquitoes. Forages low over ground near wells and bushes, over water and among livestock; also over cultivated land and towns. Small feeding flocks occasionally noted. Drinks in flight, by dipping bill into surface of water.

Breeding. Breeds mid-Mar to Jun in Morocco (longer in wet years), mid-Apr to mid-Jun in Algeria and Tunisia, and from mid-May in Turkmenistan. Possibly double-brooded. Nest-site among stones, sheltered by small bushes, in open, or in depression in ground; no nest, eggs laid on ground. Clutch 1-2 eggs, elliptical, smooth or glossy, cream or whitish, marbled and blotched pale olive and grey; incubation beginning with first egg, mainly by female, period c. 17-18 days,

eggs usually hatching asynchronously; chick semi-precocial, covered in pale buff or sandy-buff down, fledges in c. 4 weeks.

Movements. Nominate race migratory in much of range, partially sedentary in Egypt. Leaves breeding grounds by Sept and migrates on broad front, SE across Arabian Peninsula (Sept-Nov). Small numbers may overwinter in Arabia, but main wintering range in E Sahelian zone of Africa. Recorded NE & SE Egypt, C & NE Sudan (Oct-Mar), N & NE Chad, and NE Nigeria. Rarer N & C Ethiopia (Dec-Jan), NW Somalia (one Dec record), E Mali (Jan-Apr) and N Togo (possibly vagrant, May-Jun). Return movements late Feb to early Jun (mainly mid-Mar to mid-May). Race *saharae* migratory, leaving breeding grounds Sept-Oct and moving S & SW. Wintering range in W Africa, from S Mauritania (Sept-Feb) and N Senegal (Dec-Feb) through C & SC Mali (Nov-Feb) to N Burkina Faso, SE Niger and NE Nigeria. Return movements Mar-Apr. Vagrants recorded in Britain, Sweden, Germany, Italy, Sicily, Malta and Cyprus.

Status and Conservation. Not globally threatened. Widespread from Tarfaya to Taouz in Morocco; formerly common in Tunisia but now apparently scarce; locally scarce to common in Egypt. Apparently disappeared from Israel as a breeding species by 1940's, possibly because of loss of habitat to agriculture and urban construction, although a few birds occasionally summer and may therefore attempt breeding. Formerly common in Iraq but now possibly rarer; possibly common to locally abundant in S & E Iran, Baluchistan, Afghanistan, Turkestan and N & S Tadjikistan; scarce summer visitor to W edges of Chagai, Pakistan, though possibly under-recorded. In winter, locally uncommon to common in S Mauritania (Nouakchott region); fairly common but local in N Senegal (at Richard Toll); probably not uncommon locally in NE Nigeria; sparsely distributed but locally common in C & S Mali; widespread but sparsely distributed and generally uncommon in Sudan (N of L No). No data available from other regions.

Bibliography. Abdulali & Hussain (1972a), Ashford & Bray (1977), Baha el Din (1995), Bakaev & Norov (1990), Bannerman (1953), Barlow *et al.* (1997), Cave & Macdonald (1955), Cowan (1982), Cramp (1985), Dementiev & Gladkov (1951), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Dupuy (1970), Elgood, Fry & Dowsett (1973), Elgood, Heigham *et al.* (1994), Échécopar & Hùe (1964), Evans (1994), Flint *et al.* (1984), Fry *et al.* (1988), Goodman *et al.* (1989), Grimmett *et al.* (1998), Hùe & Échécopar (1970), Jackson (1985c, 1986), Knystautas (1993), Ledant *et al.* (1981), Lyngs (1986), Mackworth-Praed & Grant (1957, 1970), Nikolaus (1989), Paz (1987), Porter, Christensen & Schierner-Hansen (1996), Roberts (1991), Robin (1969), Shirihai (1996), Snow & Perrins (1998), Sopyev (1967), Stepanyan (1990), Swash & Cleere (1989), Symens *et al.* (1992), Vaurie (1960b), Zhao Zhengjie (1995).

54. Sykes's Nightjar

Caprimulgus mahrattensis

French: Engoulevent de Sykes **German:** Sykesnachtschwalbe **Spanish:** Chotacabras Mahratta
Other common names: Sind Nightjar

Taxonomy. *Caprimulgus Mahrattensis* Sykes, 1832, Mahrattas.
Monotypic.

Distribution. SE Iran, S Afghanistan, Pakistan and possibly NW India. Winters in W & C India.

tips. Iris dark brown, bill dark brown, legs and feet pale fleshy-brown. Smaller than *C. aegyptius*, which generally lacks white wing spots, although underwings are white; male of that species has narrow buffish-white tips to two outermost tail feathers, female having buffish tips. Immature paler and plainer than adult. **VOICE.** Song of male is an evenly pitched churr given from ground, mainly at dusk and dawn. Calls include soft "chuk-chuk" or "cluk-cluk" notes.

Habitat. Mainly semi-deserts with scattered thorn scrub; also dry stony scrubland, gravel or clay plains, flat salty ground with tamarisks, and stony wasteland. Occasionally found in dry hilly areas with rocky outcrops, and sparsely vegetated sand dunes in deserts. Tends to avoid cultivation. Lowland species, recorded from sea-level to 500 m.

Food and Feeding. Feeds on moths, beetles and other insects. Foraging flight agile and buoyant, and hunts low over open country, including swamps.

Breeding. Breeds Feb-Aug (mainly Mar-May) in Pakistan and possibly Feb-Jun in NW India (Punjab); no data from other regions. Possibly semi-colonial at times. Nest-site in full sunlight, or sheltered beneath clump of grass or small bush, e.g. tamarisk or bramble; no nest, eggs laid on bare, stony or salt-encrusted ground. Clutch 2 eggs, elliptical, greyish-white, smeared and blotched grey; incubation usually by female, period c. 17-18 days; chick semi-precocial, covered in grey and black speckled down.

Movements. Poorly known. Sedentary and partially migratory. After breeding season, disperses widely and winters throughout W & C India, where recorded from Rajasthan, Kutch, N Gujarat, Saurashtra, W Khandesh, Deccan and Konkan S to N Mysore.

Status and Conservation. Not globally threatened. Locally common in many regions within breeding range, widely but sparsely distributed in winter. Widespread and common in Pakistan, where mainly resident, but breeding visitor only to foothills of Salt Range, Thal and lower Kurram Valley. Present in Khirtar National Park, 80 km NW of Karachi.

Bibliography. Abdulali & Hussain (1971b), Ali & Ripley (1983), Daniels (1997), Evans (1994), Grimmett *et al.* (1998), Hollom *et al.* (1988), Hùe & Échécopar (1970), Kalsi (1998), Kazmierczak *et al.* (1998), Mukherjee (1995), Porter, Christensen & Schierner-Hansen (1996), Ripley (1982), Roberts (1991).

55. Vaurie's Nightjar

Caprimulgus centralasicus

French: Engoulevent de Vaurie **German:** Vaurienachtschwalbe **Spanish:** Chotacabras de Vaurie
Other common names: Central Asian Nightjar, Chinese/Xinjiang Nightjar

Taxonomy. *Caprimulgus centralasicus* Vaurie, 1960, Pishan, western Xinjiang, western China. Taxonomic status perhaps questionable. Known only from type specimen, an immature female originally identified as *C. aegyptius*, and compared only with that species when described; further study of immature *C. europaeus plumipes* may also be of interest. Monotypic.

Distribution. W China (SW Xinjiang), where possibly occurs throughout S Tarim basin along Kun Lun.

Descriptive notes. 19 cm. Known only from type specimen, an immature female. Upperparts sandy-buff, streaked and vermiculated brown, no nuchal collar; wing-coverts sandy-buff vermiculated brown and spotted pale buff, scapulars buff with dark central streaks; underparts pale buffish barred brown; underwing buffish but lacks white markings on wings; two outermost tail feathers narrowly tipped pale buffish-white. Iris dark brown, bill dark horn, legs and feet fleshy-brown. Smaller than *C. aegyptius*, which is slightly greyer and more spotted, with darker underwings and white underwings. Immature plumages unknown, although the only known specimen could perhaps be of an immature bird. **VOICE.** Unknown.

Habitat. Possibly arid plains and sandy foothills covered in short scrub.

Food and Feeding. Unknown.

Breeding. No information.

Movements. Unknown.

Status and Conservation. **VULNERABLE.** Restricted-range species; present in Taklimakan Desert EBA. Taxonomic status of species is perhaps questionable. Known only from type specimen, an immature female taken from Pishan (Guma) in SW Xinjiang, W China, in Sept 1929. Habitat in region of type locality has been severely damaged in recent years by grazing and trampling of livestock, cultivation and irrigation, and collection of timber for firewood. Recent surveys in 1970's and 1990's have so far failed to find this species and only *C. europaeus* has been located.

Bibliography. Collar & Andrew (1988), Collar *et al.* (1994), Duff (1994), Échécopar & Hùe (1978), Inskipp *et al.* (1996), Meyer de Schauensee (1984), Stattersfield *et al.* (1998), Vaurie (1960a), Zhao Zhengjie (1995).

56. Nubian Nightjar

Caprimulgus nubicus

French: Engoulevent de Nubie **German:** Nubischer Ziegenmelker **Spanish:** Chotacabras Nubio

Taxonomy. *Caprimulgus nubicus* Lichtenstein, 1823, Nubia.

Birds from desert regions between Mt Kilimanjaro and Tsavo formerly placed in race *taruensis*. Four subspecies currently recognized.

Subspecies and Distribution.

C. n. tamaricis Tristram, 1864 - Israel and Jordan S to SW Saudi Arabia (including one record from Farasan Is) and SW & S Yemen; some birds winter in coastal Sudan and Eritrea to NW Somalia.

C. n. nubicus Lichtenstein, 1823 - C Sudan.

C. n. torridus Lort Phillips, 1898 - Somalia, C Ethiopia, Kenya and possibly NE Uganda.

C. n. jonesi Ogilvie-Grant & Forbes, 1899 - Socotra.

Descriptive notes. 21-22 cm; male 46-55 g, 1 female 49 g. Upperparts greyish or buffish, thinly streaked blackish-brown, with crown often heavily streaked or spotted rufous; broad tawny-buff nuchal collar; wing-coverts and scapulars lightly spotted buff or heavily spotted tawny and buff; white throat patch; underparts buff barred brown. Male has large white spot on four outermost primaries and broad white tips to two outermost tail feathers; female has smaller wing and tail spots. Iris dark brown, bill dark brown, legs and feet brownish or greyish. Differs from *C. clarus* by shorter tail, and tawny or buff spotting on upperparts; also lacks

the well-marked pattern on inner wing of that species. Immature plainer and paler than adult, but otherwise similar. Races vary in coloration, amount of spotting on upperparts and wing-coverts, and extent of white on two outermost tail feathers. Voice. Song of male is a double-noted "ow-wow" or treble-noted "ow-wow-wow", given from ground.

Habitat. Typically dry, sparsely vegetated wadis, acacia scrubland (often near water), tamarisk thickets, dried riverbeds with some water, desert thorn scrub, sandy scrubland, bushy coastal dunes and possibly salt-marshes. In Yemen, also in climax acacia/euphorbia woodland. Recorded from sea-level to 1000 m, rarely to 1650 m.

Food and Feeding. Diet includes moths, grasshoppers and beetles. Forages by flitting about after prey, often hunting close to water. Also forages on ground, especially among animal droppings.

Breeding. Poorly known. Breeds Apr to perhaps Jul in Jordan and Israel, May (possibly) to Sept in Saudi Arabia (juvenile late Sept), Jun-Aug in NW Somalia (juvenile Aug) and late Mar to May in S Kenya. No nest, eggs laid on bare soil, sand or gypsum, often at base of small thorn bush. Clutch 1-2 eggs, elliptical, ivory-white or dull white, marbled or blotched lilac and brown.

Movements. Poorly known. Nominate race probably sedentary. Middle Eastern race *tamaricis* possibly sedentary and partially migratory. Some may move SW during Oct-Nov to winter in coastal lowlands of NE Sudan, Eritrea, Djibouti and NW Somalia. Autumn vagrants also recorded NE Saudi Arabia and Oman (mainly Oct). Return movements in spring noted mid-Feb to late May (mainly Mar-Apr) in Israel. Race *torridus* possibly sedentary and partially migratory. Socotran race *jonesi* probably sedentary.

Status and Conservation. Not globally threatened. Locally common in EC Sudan, C Ethiopia and N Somalia (Haud Plateau); widely distributed but uncommon and local in Kenya, where status uncertain and possibly a migrant only; scarce in Israel, Jordan, SW Saudi Arabia and coastal regions of Yemen; probably not common on Socotra Is, though possibly under-recorded. Decline in Israel noted since 1980's, population possibly reduced to no more than 15-20 breeding pairs and on brink of extinction, probable causes being loss of habitat, use of pesticides in farming, and increased road mortalities.

Bibliography. Archer & Godman (1937-1961), Ash & Miskell (1983b, 1998), Britton (1980), Brooks *et al.* (1987), Cave & Macdonald (1955), Cramp (1985), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Dowsett *et al.* (1977), Evans (1994), Fry *et al.* (1988), Gallagher & Rogers (1980), Gallagher & Woodcock (1980), Goodman *et al.* (1989), Hollom *et al.* (1988), Húe & Étchécopar (1970), Jennings (1995), Kirwan *et al.* (1996), Lewis & Pomeroy (1989), Mackworth-Præd & Grant (1957), Nikolaus (1987), Paz (1987), Peters & Loveridge (1936), Porter, Christensen & Schiermacker-Hansen (1996), Porter, Martins *et al.* (1996), Shirihai (1996), Short *et al.* (1990), Smith (1957), Snow (1978), Swash & Cleere (1989), Symens *et al.* (1992), Urban & Brown (1971), Zimmerman, D.A. *et al.* (1996).

57. Golden Nightjar

Caprimulgus eximius

French: Engoulevent doré **German:** Prachtnachtschwalbe **Spanish:** Chotacabras Dorado

Taxonomy. *Caprimulgus eximius* Temminck, 1826, Sennar, Sudan.

Two subspecies recognized.

Subspecies and Distribution.

C. e. simplicior Hartert, 1921 - S Mauritania and N Senegal E to C Chad.

C. e. eximius Temminck, 1826 - C Sudan.

Descriptive notes. 23-25 cm; 1 male 66 g. Sexes similar. Upperparts and wing-coverts tawny or tawny-buff, with greyish-white rectangular spots edged and densely speckled dark brown; no nuchal collar; large white throat patch; underparts similar to upperparts, becoming paler and unmarked on lower breast and belly. Both sexes have large white spot on four outermost primaries and broad white tips to two outermost tail feathers. Iris, bill, legs and feet all greyish-black. Immature similar to adult but paler and plainer. Race *simplicior* paler and buffier. Voice. Song of male is a prolonged churr given from ground.

Habitat. Typically, sparsely vegetated semi-desert with grass and scrub, in sandy, gravelly, stony or rocky country; also fallow cultivation. In N Senegal, also open, sandy country with scattered trees. Tends to avoid wooded areas and dense scrub. Lowland species, recorded from sea-level to 600 m.

Food and Feeding. Feeds on moths, grasshoppers, mantises, bugs and beetles. Forages at dusk, often close to or over water. Foraging methods poorly known.

Breeding. Poorly documented. Breeds Apr-May in N Senegal and Mali, Mar-Apr in Sudan; no data from other regions. No nest, eggs laid on bare ground, usually near vegetation or clump of grass. Clutch usually 2 eggs, ovate, greyish-white or greyish-buff, heavily blotched greyish or yellowish-brown over mauve; chick covered in rufous-isabelline down.

Movements. Generally sedentary, although in W of range race *simplicior* may disperse after breeding and undertake some local movements; occasionally strays farther afield, as vagrant recorded at Guellet du Zemmour in SW Morocco.

Status and Conservation. Not globally threatened. Uncommon, perhaps even rare, in N Senegal (rare in Djoudj National Park but more frequently recorded near Richard Toll), common in SW Mauritania (S of Nouakchott), fairly common and widespread in C Mali, and not uncommon in parts of Sudan. No data available from other regions.

Bibliography. Balança & de Visscher (1997), Bannerman (1953), Barlow *et al.* (1997), Brouwer & Mullié (1992), Cave & Macdonald (1955), Cleere (1995b), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fry *et al.* (1988), Gee (1984), Giraudoux *et al.* (1988), Lamarehe (1980), Mackworth-Præd & Grant (1957, 1970), Morel & Morel (1990), Nikolaus (1987), Rodwell *et al.* (1996), Rothschild & Wollaston (1902), Snow (1978).

58. Large-tailed Nightjar

Caprimulgus macrurus

French: Engoulevent de Horsfield **Spanish:** Chotacabras Macruro

German: Langschwanz-Nachtschwalbe

Other common names: Long-tailed Nightjar (!)

Taxonomy. *Caprimulgus macrurus* Horsfield, 1821, Java.

Forms superspecies with *C. atripennis*, *C. manillensis* and *C. celebensis*, and all four were formerly considered conspecific. Race *schlegelii* includes possible races: *schillmolleri* (N Moluccas and W Papuan Is); *obiensis* (NC Moluccas); *mesophanis* (S Moluccas); *oberholseri* (W Lesser Sundas); *kuehni* (Kai and Tanimbar); *yorki* (Bismarck Archipelago to N Australia); and *meeki* (Louisiane Archipelago). In past, birds of SE Asia occasionally separated as race *ambiguus*, those of Hainan as race *hainanus*. Seven subspecies currently recognized.

Subspecies and Distribution.

C. m. albonotatus Tickell, 1833 - NE Pakistan and N & E India E to Bhutan and Bangladesh.

C. m. bimaculatus Peale, 1848 - NE India E to S China, and S to Sumatra and Riau Archipelago.

C. m. andamanicus Hume, 1873 - Andaman Is (possibly absent from Little Andaman).

C. m. johnsoni Deignan, 1955 - SW Philippines (Palawan and probably Calamian Group).

C. m. salvadorii Sharpe, 1875 - W & N Borneo (Sarawak, Brunei, Sabah), including Labuan, Balambangan and Banguay and S Sulu Is.

C. m. macrurus Horsfield, 1821 - Java and Bali.

C. m. schlegelii A. B. Meyer, 1874 - Wallacea, New Guinea and New Britain to coastal N & NE Australia.

Descriptive notes. 25-29 cm; male 54-79 g, female 60-72 g, unsexed 55-90 g. Sexually dimorphic. Upperparts greyish-brown streaked blackish-brown, broadly so on crown; indistinct buff or tawny-buff nuchal collar; wing-coverts greyish-brown, spotted buff or tawny-buff, with lesser coverts darker and scapulars blackish-brown, broadly bordered buff on outer webs; white submoustachial stripe and large white throat patch; underparts brownish, barred and speckled buff, becoming buff barred brown on belly and flanks. Male has large white spot on four outermost primaries and broad white tips to two outermost tail feathers; female has

buff wing spots and narrow buff or buffish-white tips to two outermost tail feathers. Iris dark brown, bill blackish, legs and feet blackish. Differs from *C. atripennis* by darker head and more streaking on crown; that species is more rufous on hindneck, mantle, back and breast; male has smaller white wing spots and female smaller buff spots. *C. manillensis* is smaller and more spotted and shows buffish line across wing-coverts; male has smaller white wing spots and narrower white tips to two outermost tail feathers, female often having buffish wing spots. *C. celebensis* has smaller white wing spots and narrower white tips to two outermost tail feathers. Immature of present species similar to adult but duller and tawnier. Races differ mainly in size and overall coloration. Voice. Song of male is a continuous chopping or knocking, "tok, tok, tok, tok", given from perches and ground and occasionally in flight. Calls include low grunts, croaks or growls; and in flight a treble-noted "chok-a-chok"; makes guttural hissing sounds during distraction displays.

Habitat. Varied, though often preferring areas with trees. Inhabits deciduous forests and woods, bamboo forests and thickets, monsoon and coastal forests, edges of rainforest, secondary forest and scrub, forest clearings, forested foothills, and thick bush; also in open country, savanna, mid-montane and other grasslands, disturbed habitats, suburban gardens, villages, cultivation and coffee estates, along roadsides, by broad forest rivers or dry stream beds, near beaches, on offshore islands and river sandbanks, and in mangroves, swamps and overgrown creeks. Recorded from sea-level to 2700 m in N parts of range, 0-2000 m in New Guinea, 0-1200 m in Borneo and Wallacea, and 0-900 m in Sumatra. In N Pakistan, birds arriving in summer occur between 460-900 m.

Food and Feeding. Diet includes moths, crickets, grasshoppers, wasps, earwigs, bugs and beetles. Forages by making flycatching sallies from perches or ground. Also hawks after prey or feeds on ground. Feeding range may cover c. 50 ha. Occasionally hovers near grazing livestock, preying on insects disturbed or attracted by them.

Breeding. Breeds Mar-May in N India and Myanmar, Mar-Jun in N Thailand, Mar-Apr in Andamans, Jan to perhaps Jun in Malay Peninsula, Jan-May in Sumatra, Jul on Palawan, up to Apr in Sarawak,

Sept-Feb in Java, Oct on Flores, Sept on Bacan, Sept-Jan in New Guinea (also Jul in W highlands), and Sept-Nov (occasionally Aug-Jan) in N & NE Australia. Probably single-brooded. In parts of range, may be loosely colonial; territorial. Nest-site beneath tree or bush, near stones, on lawn or grass, in open area, along forest and woodland edges, on hillside or on seashore, may be used for several years in succession; no nest, eggs laid on leaf litter, bare earth or sand. Clutch 1-2 eggs, elliptical or oval, glossy, whitish, cream, pale pinkish-cream or salmon-buff, indistinctly blotched and spotted grey, pale purplish-brown and lavender; incubation usually by female during day, period c. 16-22 days; adults threatened at nest-site perform injury-feigning distraction display; chick semi-precocial, covered in pinkish-buff down, speckled and mottled blackish, brooded for c. 14 days, independent at c. 35 days.

Movements. Poorly documented. Most populations appear to be mainly sedentary. Race *albonotatus* sedentary and partially migratory, e.g. summer breeding visitor to Pakistan, arriving from mid-late Mar and leaving again in Sept, when probably moves E. In other parts of range, less frequent Oct-Feb and may be subject to some local movements. Race *schlegelii* generally sedentary, but may undertake local movements in parts of range. In Australia, possibly occurs as a vagrant as far S as Queensland/New South Wales border.

Status and Conservation. Not globally threatened. Common to locally abundant throughout much of range. In NE Pakistan, scarce and local summer visitor only. Widely distributed throughout Andaman Is, though possibly absent from Little Andaman and absent from nearby Nicobar Is; locally common in W Malaysia. Widespread but locally uncommon to fairly common throughout Wallacea, though scarce at many localities and absent from others; fairly common on Palawan; locally common in Brunei and possibly also Sarawak and Sabah; possibly scarce in Sumatra; locally common in Java; widespread in Moluccas. Widely but patchily distributed in New Guinea where locally common to very common, and in some regions such as E Highlands quickly colonizes areas where forests have been cleared. In Australia, widely distributed in N & E, where not greatly threatened, although local populations may vacate areas where habitat degraded by trampling of large animals such as feral water buffalo (*Bubalus bubalis*).

59. Jerdon's Nightjar *Caprimulgus atripennis*

French: Engoulevent de Jerdon

Spanish: Chotacabras Marajá

German: Maharadschanachtschwalbe

Other common names: Long-tailed Nightjar(!), Indian Long-tailed Nightjar; Ceylon Nightjar (*aequalis*)

Taxonomy. *Caprimulgus atripennis* Jerdon, 1845, Eastern Ghats, India.

Forms superspecies with *C. macrurus*, *C. manillensis* and *C. celebensis*, and all four were formerly considered conspecific. Occasionally treated as monotypic. Two subspecies normally recognized.

Subspecies and Distribution.

C. a. atripennis Jerdon, 1845 - Western Ghats (Kerala N to S Maharashtra) and Eastern Ghats (Tamil Nadu N to Durgapur, West Bengal).

C. a. aequalis Ripley, 1945 - Sri Lanka.

Descriptive notes. 25.5-27 cm; 1 male 55 g. Sexually dimorphic. Crown greyish-brown, central feathers boldly but sparsely spotted or streaked blackish-brown; rest of upperparts greyish-brown tinged rufous; nuchal collar rufous, often ill-defined; lesser coverts dark brown speckled rufous, rest of wing-coverts greyish-brown, speckled and spotted buff; scapulars blackish-brown, with pale tawny bar across middle of each feather; underparts brownish speckled buff, cinnamon and rufous-buff, becoming buff barred brown on belly and flanks. Male has white spot on four outermost primaries and broad white tips to two outermost tail feathers. Female has buff wing spots and buff or buffish-white tips to two outermost tail feathers. Iris brown, bill dark brown, legs and feet dark brown. *C. macrurus* is greyer-brown with crown more heavily streaked blackish-brown; male has larger white wing spots, female larger buff spots. *C. asiaticus* is smaller with heavier streaking on crown, a tawny-buff nuchal collar and heavier tawny-buff spotting on wing-coverts. Immature of present species similar to adult but paler, with crown less heavily spotted. Race *aequalis* is darker, especially on upperparts. Voice. Song of male is a repetitive, liquid "ow-r-r-r", often preceded by low "grog" sounds; sings from perches, mainly at dusk and dawn.

Habitat. Mainly forest, woods and forested country; evergreen forest, moist deciduous forest, dry forest, mixed bamboo forest and second-growth forest; also coffee estates and wooded suburban areas. In Sri Lanka, also semi-cultivated country and scrubland, especially with trees or tracts of woodland. Recorded from sea-level to 2000 m.

Food and Feeding. Poorly documented. Feeds on insects, especially beetles, moths and termites. Forages in powerful, swooping flight, interspersed with frequent glides.

Breeding. Poorly studied. Breeds Mar-Jul (mainly Mar-Apr) in India, Feb-May and Aug-Sept in Sri Lanka. No nest, eggs laid usually on sandy ground, often close to or beneath shrub or bush. Clutch 2 eggs, elliptical, cream or buffish, sparsely spotted and speckled brown, dark brown and grey; sexes share incubation; chick semi-precocial, but not described.

Movements. None documented. Sedentary.

Status and Conservation. Not globally threatened. Reported to be reasonably common throughout its range, although details lacking. Occurs in several protected areas, including Rajiv Gandhi

(Nagarhole), Mudumalai and Indira Gandhi National Parks (India); also, in Sri Lanka, found in Uda Walawe and Yala National Parks, being common in latter.

Bibliography. Ali & Ripley (1983), Gauntlett (1995), Grimmer *et al.* (1998), Henry (1998), Inskipp (1995), Inskipp *et al.* (1996), Marshall (1978), Mees (1977a, 1985b), Phillips (1978), Ripley (1945, 1982), Ripley & Beehler (1987), Whistler & Kinnear (1935).

60. Philippine Nightjar *Caprimulgus manillensis*

French: Engoulevent des Philippines

Spanish: Chotacabras Filipino

German: Philippinennachtschwalbe

Taxonomy. *Caprimulgus manillensis* Walden, 1875, Manila.

Forms superspecies with *C. macrurus*, *C. atripennis* and *C. celebensis*, and all four were formerly considered conspecific; in recent years has commonly been lumped with *C. celebensis*, but differs in both voice and morphology. Proposed race *delacouri* for Mindanao birds is not distinct. Monotypic.

Distribution. Philippines (except SW).

Descriptive notes. 23-25 cm; male 59-68 g, female 58-71 g. Sexes similar. Upperparts greyish-brown streaked blackish-brown, broadly so on crown, with no nuchal collar; indistinct buffish line across wing-coverts; lesser coverts dark brown flecked tawny, rest of wing-coverts greyish-brown, spotted blackish-brown, tawny, buff and pale buff; scapulars blackish-brown, broadly edged buff on outer webs; white band around throat; underparts greyish-brown speckled brown and spotted buff, becoming buff barred brown on belly and flanks. Both sexes have white spot on second, third and fourth outermost primaries and white

tips to two outermost tail feathers. Iris dark brown, bill blackish, legs and feet blackish. *C. macrurus* is larger and more variegated; male has larger white wing spots and broader, whiter tips to two outermost tail feathers, female having buff wing and tail markings. *C. celebensis* tends to show whiter tips to two outermost tail feathers. Immature similar to adult but browner and paler. Voice. Song of male is a repetitive "took-toor-r-r" given from perches, mainly at dusk and dawn.

Habitat. Typically primary and secondary forest, pine forest and second growth; also scrubland, open country with clumps of trees, mangroves, town and village outskirts, agricultural areas and by rocky beaches. Recorded from sea-level to 2000 m.

Food and Feeding. Probably feeds on insects. Foraging methods not documented.

Breeding. Poorly known. Breeds Apr-May, possibly longer, throughout range. No nest, eggs laid on leaf litter on ground, usually in forest or woodland clearing, or beside track or path. Clutch 1-2 eggs, elliptical or ovate, whitish, heavily blotched and spotted brown, dark brown and grey; chick semi-precocial, covered in brownish-rufous down.

Movements. None documented. Sedentary.

Status and Conservation. Not globally threatened. Widespread but probably not common anywhere throughout its range. Fairly common in Angat forest, near Manila, Luzon. Occurs in Rajah Sikatuna National Park (Bohol) and Mount Katanglad National Park (Mindanao).

Bibliography. Brooks, Dutson *et al.* (1996), Brooks, Evans *et al.* (1992), Danielsen *et al.* (1994), Delacour & Mayr (1946), Dickinson *et al.* (1991), Evans, Dutson & Brooks (1993), Inskipp *et al.* (1996), Marshall (1978), McGregor (1904, 1905), Mees (1977a, 1985b), Ogilvie-Grant (1894), Rabor (1977), Rand & Rabor (1960).

61. Sulawesi Nightjar *Caprimulgus celebensis*

French: Engoulevent des Célèbes

Spanish: Chotacabras de Célebes

German: Sulawesinachtschwalbe

Taxonomy. *Caprimulgus celebensis* Ogilvie-Grant, 1894, Sulawesi.

Forms superspecies with *C. macrurus*, *C. atripennis* and *C. manillensis*, and all four were formerly considered conspecific; in recent years has commonly been lumped in *C. manillensis*, but differs in both voice and morphology. Two subspecies recognized.

Subspecies and Distribution.

C. c. celebensis Ogilvie-Grant, 1894 - N & CE Sulawesi; probably also Buton I in SE.

C. c. jungei Neumann, 1939 - Sula Is, where currently known from Taliabu and Mangole.

Descriptive notes. 24-30 cm. Sexes similar. Upperparts greyish-brown streaked blackish-brown, broadly so on central crown, with no nuchal collar; lesser coverts dark brown speckled tawny and buff, rest of wing-coverts greyish-brown, boldly spotted buff, pale buff and tawny; scapulars blackish-brown edged buffish; white throat patch; underparts greyish-brown, speckled and spotted brown, greyish-white and buff, becoming buff barred brown on belly and flanks. Both sexes have white spot on second, third and fourth outermost primaries and white tips to two outermost tail feathers. Iris dark brown, bill blackish, legs and feet blackish. Differs from *C. manillensis* by whiter tips to two outermost tail feathers. Smaller and plainer than *C. macrurus*, with smaller white wing spots and narrower white tips to two outermost tail feathers in male. Paler and less spotted than *Eurostopodus diabolicus*, which has broad band around throat, smaller white wing spots and no white on tail. Race *jungei* has smaller white tips to two outermost tail feathers. Voice. Song of male is an accelerating "tok, tok, tok, tr, tr, tr", last notes softer and trailing off; sings from perches, mainly at dusk.

Habitat. Typically, secondary forest, coastal bush and edges of mangroves. On Taliabu, lowland forest, including lightly logged areas.

Food and Feeding. Poorly documented. Probably feeds on insects. Forages by hawking after prey in buoyant and agile flight.

Breeding. Breeding habits not documented.

Movements. None documented. Probably sedentary.

Status and Conservation. Not globally threatened. Restricted-range species; present in Sulawesi EBA and Banggai and Sula Islands EBA. Locally rare to fairly common in parts of N & E Sulawesi, but clearly under-recorded; only recently discovered on Buton I, where status uncertain; in Sula Is. reasonably common on Taliabu and uncommon on Mangole. Present in Tangkoko Nature Reserve (NE Sulawesi). Loss of habitat due to deforestation probably most serious threat throughout its range. **Bibliography.** Andrew (1992, 1993), Catterall (1997), Coates & Bishop (1997), Davidson *et al.* (1995), Holmes & Phillips (1996), Inskipp *et al.* (1996), Mees (1977a, 1985b), Rozendaal (1990), Stones, Lucking *et al.* (1997), Watling (1983), White & Bruce (1986).

62. Donaldson-Smith's Nightjar

Caprimulgus donaldsoni

French: Engoulevent des épines

Spanish: Chotacabras Espinero

German: Dornbusch-Nachtschwalbe

Taxonomy. *Caprimulgus donaldsoni* Sharpe, 1895, Hargeysa, Somalia.

Monotypic.

Distribution. NW Somalia to NE Tanzania; possibly also SE Sudan.

Descriptive notes. 18 cm; male 21–36 g, female 26–36 g. Sexually dimorphic, but only slightly so. Upperparts greyish streaked brown; wing-coverts chestnut or rufous, streaked brown and spotted buffish; broad rufous, tawny and buff nuchal collar; underparts chestnut or rufous, heavily spotted buff, becoming dark buff barred brown on belly. Male has white spot on four outermost primaries and broad white tips to two outermost tail feathers; female has smaller white markings. Iris, bill, legs and feet all dark brown. Some variation in general coloration, and greyer or browner birds occur. Immature similar to adult female but rather rufous. **VOICE.** Song of male is a series of melodious whistles, “tu-wee, tu”, given from ground mainly at dusk and dawn.

Habitat. Mainly arid or semi-arid scrubland and bush country, also wooded wadis, from sea-level to 1700 m.

Food and Feeding. Diet includes ants, grasshoppers, moths, beetles and caterpillars. Forages by hawking after prey, often close to ground or over water. When hunting, flight is extremely rapid and agile. Occasionally takes food from ground.

Breeding. Poorly documented. Breeds May–Jun in Somalia, and possibly Aug–Oct in Kenya. No nest, eggs laid usually on sandy ground, generally beneath vegetation such as small bush. Clutch 2 eggs, ovate, dullish ivory,

heavily marbled greyish-brown on patches of violet-grey; chick not described.

Movements. Poorly understood and possibly sedentary in parts of its range; common in Ilemi Triangle (S Sudan) in Feb and Jun, but apparently absent Nov–Dec and occurrence there possibly seasonal only.

Status and Conservation. Not globally threatened. Widespread and locally common to abundant up to 1400 m throughout range, less common at higher altitudes. Seasonally common in suitable habitat in SE Sudan, where may not breed; locally uncommon to common in Kenya and N Tanzania. Present in Tsavo West, Tsavo East and Awash National Parks (Kenya).

63. Black-shouldered Nightjar

Caprimulgus nigriscapularis

French: Engoulevent à épaulettes noires

Spanish: Chotacabras Hombro Negro

German: Schwarzschilder-Nachtschwalbe

Other common names: Dusky Nightjar(!)

Taxonomy. *Caprimulgus nigriscapularis* Reichenow, 1893, Songa, west of Lake Albert. Often considered conspecific with *C. pectoralis*; these two form superspecies with *C. poliocephalus* and *C. ruwenzorii*. Monotypic.

Distribution. Patchily from Gambia, Senegal and W Sierra Leone E through Nigeria and Cameroon to SE Sudan and W Kenya, and S to Congo and SW Zaire.

Descriptive notes. 23-25 cm; male 48-50 g. Sexually dimorphic. Upperparts generally dark brown tinged rufous; broad tawny-buff nuchal collar; lesser coverts blackish-brown, rest of wing-coverts brown spotted buffish; scapulars blackish-brown edged buff; white throat patch; underparts rufescent-brown, becoming tawny-buff on belly and flanks. Male has small white spot on four outermost primaries and broad white tips to two outermost tail feathers; female has slightly smaller white markings. Iris dark brown, bill blackish, legs and feet dark brown. More rufous than *C. pectoralis*, with more strikingly patterned wing-coverts, rufous

nuchal collar and smaller white wing spots. Paler and more rufous than *C. poliocephalus* and *C. ruwenzorii*, with less white on two outer tail feathers. Immature similar to adult but more rufous. **VOICE.** Song of male is an evenly pitched, double-noted whistle, "pee-u-o, piririri" or "pee-u-o, pererere", second note being trilled, often preceded by a rapid series of "werp" notes. Sings from perches at dusk and dawn and on moonlit nights. Calls include soft "chuk", "tuc" and double "tuc-tuc" sounds.

Habitat. Favours mainly edges of lowland forest: dense woodland, gallery forest, rainforest, secondary growth, and sparsely wooded, grassy or stony hillsides. In W Kenya, also mossy thickets with small trees. Recorded from sea-level to c. 2000 m.

Food and Feeding. Poorly studied. Feeds on moths, beetles and other insects. Forages by hawking for prey among trees, in clearings, over open areas or above hillsides.

Breeding. Breeds possibly May in Gambia, Aug-Dec (chicks found Sept and Dec) in W Zaire, Apr-Aug in N Zaire, Jan-Feb in NE Zaire, Feb-Jun and Sept-Dec in Uganda, and Jul-Mar (singing males) in S Nigeria. No nest, eggs laid on ground, usually on leaf litter, often in woodland clearing. Clutch 1-2 eggs, elliptical, pale or creamy pink, speckled reddish-brown and grey, markings usually concentrated in band around blunt end; incubation period not documented; chick semi-precocial, covered in pale greyish-buff down, fledging period unknown; adults threatened at nest-site may perform injury-feigning distraction display.

Movements. None documented. Possibly sedentary.

Status and Conservation. Not globally threatened. Frequent to common in many parts of range, and probably more common and widespread than currently documented. Few records W Senegal, W Gambia, Guinea Bissau and W Sierra Leone; possibly locally common in Ivory Coast, e.g. Comoé National Park; possibly not common in Ghana; rare in Togo; fairly common in forest zone in S Nigeria; possibly not uncommon in W Cameroon; locally common in E Zaire; not uncommon locally in W & S Uganda; locally common in Rwanda and Burundi, occurring in Ruwuvu National Park; local and uncommon in W Kenya; fairly common in extreme S Sudan.

Bibliography. 64. Fiery-necked Nightjar

Caprimulgus pectoralis

French: Engoulevent musicien

German: Pfeifnachtschwalbe

Spanish: Chotacabras Músico

Other common names: African Dusky Nightjar

Taxonomy. *Caprimulgus pectoralis* Cuvier, 1817, Knysna, Cape Province.

Often considered conspecific with *C. nigriscapularis*; these two form superspecies with *C. poliocephalus* and *C. ruwenzorii*. The three more northerly races have been considered so distinct from nominate that they may represent an incipient species (*C. fervidus*). Four subspecies currently recognized.

Subspecies and Distribution.

C. p. shelleyi Bocage, 1879 - Angola and S Zaire E to Tanzania and SE Kenya.

C. p. fervidus Sharpe, 1875 - S Angola, N Namibia, N & E Botswana and Zimbabwe to NE South Africa.

C. p. crepusculans Clancey, 1994 - S Malawi (possibly), SE Zimbabwe and Mozambique to E South Africa and E Swaziland.

C. p. pectoralis Cuvier, 1817 - S South Africa.

Descriptive notes. 23-25 cm; male 41-66 g, female 38-66 g. Sexually dimorphic. Upperparts dark brown, variegated greyish-brown and brownish-white, showing two or three rows of pale spots across wing-coverts; broad buff or tawny-buff nuchal collar; white submoustachial stripe and large white throat patch; underparts brown, speckled and barred brownish-white and buff. Male has large white spot on four outermost primaries and broad white tips to two outermost tail feathers; female has smaller, buffier white markings. Iris brown, bill blackish, legs and feet brown. Generally greyer and browner than *C. nigriscapularis*, especially on underparts, with buffier nuchal collar, paler lesser coverts and larger white wing spots. Paler and greyer than *C. poliocephalus* and *C. ruwenzorii*, with less white on two outermost tail feathers. Immature similar to adult but often paler and more

rufous. Races vary in overall coloration, in extent and coloration of nuchal collar, and in amount of barring on underparts; *fervidus* has a distinctive rufous morph, and this may also be present in other races. **VOICE.** Song of male is a melodious but variable whistle, "pee-u-o, piririri", first note undulating, second an evenly pitched trill, often preceded by a series of "werp" notes. Sings from perches, mainly at dusk and dawn and on moonlit nights. Alarm calls include "woot, woot, woot" notes and soft "chuk"; chirrs and guttural hissing sounds are given during distraction, threat or defence displays.

Habitat. Typically *Brachystegia* woodland savanna (miombo), but also commonly mopane and other deciduous woodland; in addition, occurs in scrubland, eucalyptus plantations, riparian forest, thickets and suburban gardens. Avoids thick forest interior but frequents forest edge. Recorded from sea-level to 1500 m.

Food and Feeding. Diet includes mantises, spiders, moths, grasshoppers and beetles. Forages by making flycatching sallies from perches. Also hawks for prey in flight and often feeds on insects disturbed or attracted by grazing animals. Drinks in flight.

Breeding. Breeds Aug-Sept in Angola, Sept-Nov in Zambia and Malawi, from Sept generally in E Africa, Aug-Dec in Botswana and Zimbabwe, and Aug-Nov in South Africa; in all areas periods possibly longer than given, and usually begin towards start of rains. Double-brooded, second clutch may be started 33 days after first hatches. Monogamous and territorial; territory up to 5-8 ha. Nest-site usually beneath tree within woodland, copse or wooded tract, also in thicket or acacia stand, tends to avoid arable land; no nest, eggs laid on leaf litter on ground. Clutch 1-2 eggs, usually 2, elliptical, glossy ivory-white to pale or creamy pink, plain or spotted and blotched reddish-brown, grey and dark pink, laid on successive days; incubation begins as soon as first egg laid, usually by female during day, period c. 18 days, eggs usually hatching asynchronously but on one occasion synchronously at night; replacement often laid if clutch lost; adults threatened at nest-site may perform injury-feigning distraction display; chick semi-precocial, covered with brown and grey down, fledges at c. 18 days but can remain dependent for further 24 days; young may stay in breeding area for up to 62-145 days.

Movements. Nominate race sedentary and partially migratory. At end of breeding season, moves N and NE (Apr-May) as far as SE Zimbabwe; one record from Barotse Province, Zambia, in Jul. Return movements to breeding grounds begin about early Sept. Race *shelleyi* sedentary and possibly partially migratory. Movements poorly understood, but at end of breeding season possibly moves S to N Namibia, N Botswana and NW Zimbabwe. Race *fervidus* migratory. Movements again poorly understood, but after breeding season probably moves N to N Zambia, SE Zaire and Tanzania. There are also possible records from Rwanda and Burundi. Race *crepusculans* possibly mainly sedentary.

Status and Conservation. Not globally threatened. Widely distributed and generally quite common throughout most of range. Few data published on population densities, though widespread and locally common in Zimbabwe, e.g. up to 20 pairs in 65 ha; locally common in coastal woodlands and forests of SE Kenya, e.g. common in Sokoke; locally common in S Zaire; widespread and common in Zambia; common in Malawi, occurring in Liwonde National Park; fairly common to very common in Botswana, where occurs in Chobe National Park; fairly common in N Namibia; locally common in NE South Africa, e.g. in Kruger National Park. Nominate race locally very common, e.g. in Bontebok Nature Reserve.

Bibliography. Aspinwall (1982), Benson & Benson (1977), Benson & Colebrook-Robjent (1977), Benson *et al.* (1971), Britton (1980), Britton & Britton (1973), Cave & Macdonald (1955), Chenuaux-Repond (1980), Clancey (1994, 1996), Cleere (1995a), Colebrook-Robjent (1979, 1984), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fry (1988a), Fry *et al.* (1988), Ginn *et al.* (1989), Gore (1990), Harrison *et al.* (1997), Harwin (1982), Hockey *et al.* (1989), Jackson (1975, 1978, 1983, 1984a, 1984b, 1985a, 1985c, 1986, 1987), Langley (1984), Lewis & Pomeroy (1989), Lippens & Wille (1976), Louette (1990b), Mackworth-Præd & Grant (1957, 1962, 1970), Maclean (1993), Masterson (1994), Penry (1994), Pinto (1983), Short *et al.* (1990), Snow (1978), Steyn (1996a, 1996b), Steyn & Myburgh (1975), Vernon & Dean (1988), Zimmerman, D.A. *et al.* (1996).

65. Abyssinian Nightjar

Caprimulgus poliocephalus

French: Engoulevent d'Abyssinie

Spanish: Chotacabras Abisinio

German: Höhnennachtschwalbe

Other common names: Montane Nightjar(!), Mountain Nightjar

Taxonomy. *Caprimulgus poliocephalus* Rüppell, 1840, Kulla, Ethiopia.

Often considered conspecific with *C. ruwenzorii*; these two form superspecies with *C. nigriscapularis* and *C. pectoralis*. Population in Saudi Arabia possibly racially distinct, requires further study. Race *guttifer* and proposed race *koesteri* of *C. ruwenzorii* have sometimes been placed in present species. Monotypic.

Distribution. SW Saudi Arabia and possibly Yemen, discontinuously through C Ethiopia to NE Uganda and N Tanzania.

Descriptive notes. 22-24 cm; male 42-50 g, female 42-50 g. Sexually dimorphic. Upperparts greyish-brown streaked blackish-brown, broadly so on central crown; broad buff or tawny-buff nuchal collar; wing-coverts are greyish-brown, speckled greyish-white and spotted pale buff; scapulars blackish-brown, broadly edged buff; whitish submoustachial stripe and white throat patch; underparts are greyish-brown, speckled and spotted buff, greyish-white and cinnamon, becoming buff barred brown on belly and flanks. Male has white spot on four outermost primaries, and two outermost tail feathers are generally

white; female has smaller white wing spots, edged or washed buff, and less white in tail. Iris dark brown, bill blackish, legs and feet darkish brown. Paler than *C. ruwenzorii*, with larger white wing spots and more white on outer tail feathers. Darker and browner than *C. pectoralis*, with more white in tail. Darker and browner than *C. nigriscapularis*, with larger white wing spots and more white in tail. Immature paler than adult and often rather rufous. Voice. Song of male is a double-noted whistle, "peuu-eee, pe-uu-uu", first note undulating, second note trilled and descending slightly in pitch. Sings from perches. Flight call is a series of deep "kah, kah, kah" notes.

Habitat. Mainly found in interior and at edges of all types of montane woodland and forest, including olive, pine, juniper and bamboo; also occurs in large wooded suburban gardens, steep rocky hillsides with scattered eucalyptus, and more open wooded areas. In Saudi Arabia, apparently prefers rocky terrain with juniper forest. Recorded at 1000-3350 m.

Food and Feeding. Feeds on moths, beetles and grasshoppers. Forages by hawking for prey in open spaces such as fields and pastures, open woodland and large suburban gardens with plenty of trees. When hunting, flight is extremely agile and rapid. Also flycatches from perches, flying with shallow wingbeats interspersed with many twists and turns. Also feeds on insects attracted to artificial lights and fires.

Breeding. Poorly documented. Breeds possibly Mar-May in Saudi Arabia, Feb-May in Ethiopia, and Sept-Jan in Sudan, Uganda, Kenya (also Mar-Apr) and N Tanzania. Monogamous and territorial. Nest-site usually in small clearing at or near base of tree or bush, in suburban garden, occasionally alone or within hedgerow; no nest, eggs laid on bare ground or leaf litter. Clutch normally 2 eggs, elliptical, creamy-pink to pinkish-buff, spotted and blotched pale brown or reddish-brown, markings heavier around blunt end; incubation mainly by female; chick not described.

Movements. None documented throughout African range and probably sedentary. In Saudi Arabia, may move to lower altitudes in winter.

Status and Conservation. Not globally threatened. Locally common throughout range. Widespread and locally common along W side of Asir Mts, SW Saudi Arabia, range possibly extending S into Yemen highlands. In Ethiopia, common in suitable forested highlands between 1800-3200 m in W, SE & Rift Valley, less common but frequent between 3200-3350 m; occurs in Bale Mountains National Park. Locally common between 1000-3000 m in SE Sudan, NE Uganda, highlands of W & C Kenya and N Tanzania.

Bibliography. Britton (1980), Brown & Britton (1980), Cave & Macdonald (1955), Cheesman & Selater (1935), Cleere (1995a), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Evans (1994), Fry (1988a), Fry *et al.* (1988), Jennings (1995), Lewis & Pomeroy (1989), Louette (1990b), Mackworth-Præd & Grant (1957), Newton (1992), Nikolaus (1987, 1989), Porter, Christensen & Schiermacker-Hansen (1996), Short *et al.* (1990), Snow (1978), Stagg (1992), Symens, Newton, Stagg & Winkler (1993), Symens, Newton, Winkler & Stagg (1992), Urban & Brown (1991), Wilson & Wilson (1994), Zimmerman, D.A. *et al.* (1996).

66. Montane Nightjar

Caprimulgus ruwenzorii

French: Engoulevent du Ruwenzori **Spanish:** Chotacabras del Ruwenzori
German: Ruwenzorinachtschwalbe
Other common names: Ruwenzori Nightjar

Taxonomy. *Caprimulgus ruwenzorii* Ogilvie-Grant, 1908, Mubuku Valley, Mt Ruwenzori. Often considered conspecific with *C. poliocephalus*; these two form superspecies with *C. nigriscapularis* and *C. pectoralis*. Angolan population has been separated as race *koesteri*, and in tail pattern appears intermediate between nominate and *guttifer*; this isolated population has even been suggested to be a separate species. Race *guttifer* has occasionally been treated as a separate species. Both of these forms have alternatively been considered races of *C. poliocephalus*. Two subspecies currently recognized.

Subspecies and Distribution.
C. r. ruwenzorii Ogilvie-Grant, 1908 - SW Uganda to E Zaire; separate population in W Angola.
C. r. guttifer Grote, 1921 - SW Tanzania, N Malawi and NE Zambia; separate population in NE Tanzania.

wing spots tinged buffish and less white on tail. Iris dark brown, bill blackish, legs and feet dark brown. Darker than *C. poliocephalus*, with smaller white wing spots and less white on two outermost tail feathers. Darker and browner than *C. pectoralis*, with smaller white wing spots and more white on tail. Darker and browner than *C. nigriscapularis*, with more white on tail. Immature similar to adult. Race *guttifer* has slightly less white on tail. Voice. Song of male is a double-noted whistle, "pee-eee, pee-uuu", first note evenly pitched, second slightly trilled. Sings from perches, mainly at dusk and dawn and on moonlit nights. Flight calls are soft "ka, ka, ka, kah" notes; other calls include soft "kweep" and "yip, yip" sounds.

Habitat. Typically, edges of all types of montane woodland and forest, including large tracts of introduced coniferous species, e.g. *Pinus patula*; also woodland clearings, open scrubland, small stands of woodland on montane grassland, bracken-covered ridges, bracken ferns and edges of bracken briers. Recorded at 1500-2800 m.

Food and Feeding. Feeds on moths, beetles and termites. Forages along edges of woods and forests, often among treetops, or over grasslands and other open areas. Also makes flycatching sallies from perches.

Breeding. Appears to be poorly documented. Breeds Aug/Sept-Mar throughout much of range, and Sept-Nov in N Malawi and NE Zambia. Nest-site in woodland clearing, burnt area, bracken brier, near rocks or boulders, on valley slope, or beneath tree, bush or sapling; no nest, eggs laid on bare ground. Clutch 1-2 eggs, elliptical, pale pinkish-cream to pale buff, speckled reddish-brown with markings denser around blunt end; chick not described.

Movements. None documented. Probably sedentary throughout whole of range.

Descriptive notes. 22-24 cm; male 43-55 g, female 41-57 g. Sexually dimorphic. Upperparts dark greyish-brown streaked blackish-brown, broadly so on central crown; broad buff or tawny-buff nuchal collar; wing-coverts dark greyish-brown, speckled greyish-white and spotted pale buff; scapulars blackish-brown, broadly edged buff; whitish submoustachial stripe and white throat patch; underparts dark greyish-brown, speckled and spotted buff and pale buff, becoming buff barred brown on belly and flanks. Male has small white spot on four outermost primaries, and two outermost tail feathers are white distally; female has white

Status and Conservation. Not globally threatened. If race *guttifer* and Angolan population are placed in *C. poliocephalus*, present species becomes restricted-range species: present in Albertine Rift Mountains EBA. Little known, but locally common in suitable habitat. Locally common in forested uplands from SW Uganda S through Rwanda, Burundi and E Zaire to SW Tanzania, N Malawi and NE Zambia; possibly also locally common in NE Tanzania and Angola. Occurs in Impenetrable Forest National Park (SW Uganda) and Kibira National Park (NW Burundi).

Bibliography. Benson & Benson (1977), Benson *et al.* (1971), Britton (1980), Chapin, J.P. (1939), Chapin, R.T. (1978), Chappuis (1981), Cleere (1995a), Colebrook-Robjent (1979), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fry (1988a), Fry *et al.* (1988), Hall (1960), Johnston-Stewart & Heigham (1982), Lippens & Wille (1976), Louette (1990b), Mackworth-Præd & Grant (1957, 1962, 1970), Newman *et al.* (1992), Pinto (1983), Short *et al.* (1990), Snow (1978), Stattersfield *et al.* (1998), Symens *et al.* (1992), Turner *et al.* (1991), Zimmerman, D.A. *et al.* (1996).

67. Indian Nightjar

Caprimulgus asiaticus

French: Engoulevent indien **German:** Hindunachtschwalbe **Spanish:** Chotacabras Hindú
Other common names: (Southern) Common Indian Nightjar, Little Indian Nightjar

Taxonomy. *Caprimulgus asiaticus* Latham, 1790, Bombay.

In past, sometimes considered conspecific with *C. madagascariensis*. Three subspecies recognized.

Subspecies and Distribution.

C. a. asiaticus Latham, 1790 - SE Pakistan and India to S Thailand and S Indochina.

C. a. eidos J. L. Peters, 1940 - Sri Lanka.

C. a. siamensis Meyer de Schauensee, 1934 - N Thailand.

Descriptive notes. 24 cm; 1 male 46 g. Sexually dimorphic. Upperparts greyish-brown streaked blackish-brown, crown broadly streaked blackish-brown edged rufous; broad buff or tawny nuchal collar; lesser coverts greyish-brown speckled rufous, rest of wing-coverts greyish-brown boldly spotted buff; scapulars blackish-brown edged buff; whitish submoustachial stripe and large white patch on either side of lower throat; underparts greyish-brown, barred brown and boldly spotted buff, becoming buff barred brown on belly and flanks. Male has white spot on four outermost primaries and broad white tips to two outer-

most tail feathers; female has smaller white wing spots, tinged or edged buff, and narrower buffish white tips to two outermost tail feathers. Iris dark brown, bill blackish, legs and feet brownish. Slightly smaller than *C. indicus*, with broader nuchal collar; male has smaller white wing spots and only two outermost tail feathers tipped white. Smaller than *C. macrurus*, with more distinct nuchal collar and more boldly spotted wing-coverts; male has smaller white wing spots and narrower white tips to two outermost tail feathers. Generally more heavily patterned than *C. affinis*, which usually lacks a nuchal collar and has less spotting on wing-coverts; male of that species often has larger white wing spots and two outermost tail feathers are entirely whitish. Juvenile paler and plainer than adult. Racial differences slight; nominate race variable in colour, with greyish-brown, sandy-buff, grey, brown and rufous birds recorded; race *eidos* possibly slightly smaller; race *siamensis* paler and more silvery-grey, with paler nuchal collar. Voice. Song of male is a distinctive "chuk-chuk-chuk-k-k-k-roo". Sings from perches and occasionally from ground, mainly at dusk and dawn and on moonlit nights. Flight calls are possibly short "quit-quit" or "chuk-chuk" notes.

Habitat. Highly variable throughout range, but typically scrubland or wooded country. Light scrub jungle, thin bamboo jungle, young forestry plantations, fallow cultivation with thickets and euphorbia hedges, stony nullahs near cultivation, and overgrown gardens. In SW Pakistan, prefers low hill country, sparsely vegetated with scattered thorn scrub, but also low stony hills and flat saline areas with tamarisk bushes. In Sri Lanka, scrubland, waste ground, tracts of jungle on sandy soils, open wooded country and cinnamon plantations. Lowland plains to foothills, from sea-level to 1500 m.

Food and Feeding. Diet includes moths, beetles, grasshoppers, crickets and bugs. During non-breeding season, also takes flowers of *Euphorbia caducifolia* and possibly small mice. Foraging behaviour not fully documented, but recorded feeding on insects attracted to artificial lights, and occasionally takes prey from ground.

Breeding. Surprisingly poorly documented. Breeds from Apr in Pakistan, Feb-Sept (mainly Apr to perhaps May) in India, Jan-Oct (mainly Mar-May and Sept) in Sri Lanka, and from mid-Mar in Thailand. Possibly double-brooded. Nest-site in open or shaded by vegetation, usually close to bush or tree stump, beneath tree or sapling, at base of man-made wall, in dry, pebbly nullah or in stony field; no nest, eggs laid on leaf litter or bare soil. Clutch 2 eggs, elliptical, cream or pale salmon-pink, spotted and smeared reddish-brown and purple; both sexes incubate, period not documented; chick covered in rufous down, fledging period not documented.

Movements. Poorly known. Nominally race possibly sedentary, and also partially and locally migratory, e.g. in S Pakistan, though movements often not fully understood. Other races appear to be sedentary.

Status and Conservation. Not globally threatened. Generally common and widespread throughout range. In S Pakistan, locally common in Thatta, Badin and Thar Park districts only; occurs in Khirtar National Park. In India, found in several protected areas, e.g. Keoladeo Ghana National Park. In Sri Lanka, common in suitable habitat in dry areas, less common in wet areas; very common in Yala National Park in dry SE of island; also occurs in Uda Walawe National Park. In Thailand, present in Khao Sam Roi Yot National Park.

Bibliography. Ali (1996), Ali & Ripley (1983), Barnes (1937), Bharos (1992), Chakravarthy & Purna Chandra Tejassvi (1992), Daniels (1997), Deignan (1945), Eames & Ericson (1996), Grinnett *et al.* (1998), Harvey (1989), Henry (1998), Hue & Fitchécar (1970), Inskipp & Inskipp (1991), Jones (1923), Lamba (1967), Legge (1983), Lekagul & Round (1991), Lowther (1937), Mahabadi & Lamba (1987), Majumdar *et al.* (1992), Marshall (1978), Mukherjee (1995), Osmaston (1921a), Parrot (1907), Phillips (1978), Porter, Christensen & Schiermacker-Hansen (1996), Rana (1988), Riley (1938), Ripley (1982), Roberts (1991), Round (1988), Smythies (1986), Stepanyan (1995), Whistler & Kinnear (1935).

68. Madagascar Nightjar

Caprimulgus madagascariensis

French: Engoulevent malgache **Spanish:** Chotacabras Malgache
German: Madagaskarnachtschwalbe

Taxonomy. *Caprimulgus Madagascariensis* Sganzin, 1840, Sainte Marie, Madagascar.
In past, sometimes considered conspecific with *C. asiaticus*. Racial differences uncertain, and species may be better considered monotypic. Two subspecies currently recognized.

Subspecies and Distribution.

C. m. aldabrensis Ridgway, 1894 - Aldabra.

C. m. madagascariensis Sganzin, 1840 - Madagascar (including Nosy Boraha).

Descriptive notes. 21-23 cm; male 37-43 g, female 45-51 g, unsexed 43-44 g. Sexually dimorphic. Upperparts greyish-brown streaked blackish-brown, generally no nuchal collar; lesser coverts greyish-brown speckled buffish and tawny, rest of wing-coverts greyish-brown, heavily spotted buff with brown centres; scapulars blackish-brown edged buff; whitish submoustachial stripe and small white patch on either side of lower throat; underparts greyish-brown thinly barred greyish-white, becoming buff barred brown on belly and flanks. Male has white spot on four outermost primaries and white tips to two outermost tail feathers; female has buff wing spots and smaller white tips to tail feathers. Iris dark brown, bill blackish, legs and feet dark brown. Paler and more variegated than *C. enarratus*, with no nuchal collar, small white wing spots, and much broader white tips to two outermost tail feathers. Immature similar to adult female. Race *aldabrensis* is occasionally paler on crown and scapulars, with broader white tips to two outermost tail feathers. VOICE. Song of male is a repetitive "tuk-tr-tr-tr-tr-tr"; occasionally gives "cop, cop, cop" notes, a soft cooing or a faint, wavering "huuu". Sings from perches or ground, throughout night. Calls include loud, liquid "wa-pit" or "tyo" and muffled "chok" sounds.

Habitat. All types of open or lightly wooded country: woodland, including partially or totally degraded areas, clearings, forest edges, savanna, heathland, scrubland, eucalyptus plantations, areas of afforestation; also in cultivated regions, near urban areas and in gardens. Tends to avoid dense forest. On Aldabra, open sandy hills, also casuarina woods with sparse understorey. Recorded from sea-level to 1800 m.

Food and Feeding. Feeds on grasshoppers, moths, cicadas and beetles. Forages by hawking around tree-tops, in open country or over water. When hunting, frequently glides with wings held above back. Usually forages alone, although large numbers may occur together where there is a plentiful food supply. On Aldabra, also hunts over sand dunes and around habitation.

Breeding. Breeds Aug to perhaps Oct in SW Madagascar, Oct-Nov in N Madagascar, and Sept-Dec on Aldabra. No nest, eggs laid usually on ground, often on leaf litter, and typically in open woodland or forest, or in clearing, apparently also on flat roof; on Aldabra, also on bare soil or gravel, often on open sandy hill, or beneath bush in clearing or alongside path in thick scrub. Clutch 2 eggs, elliptical, glossy white, blotched and spotted brownish-grey or blackish-grey; incubation probably by female during day, period not documented; adults threatened at nest-site perform defence display; chick semi-precocial, covered in brown and buff down, fledging period not documented.

Movements. None documented. Probably sedentary.

Status and Conservation. Not globally threatened. Common and widespread throughout Madagascar, especially in E; in some regions in SE, vocalizations suggest densities of up to 6 birds per 0.5 km²; occurs in Ranomafana National Park, Berenty Reserve and Perinet Special Reserve. Not uncommon on Aldabra Atoll, where population of several hundred individuals may be present, occurring on most islands, including terrestrial areas as small as 400 m². In Madagascar, environmental damage does not appear to pose immediate threat, as species apparently adaptable and tolerant of disturbed habitats; on Aldabra, natural predators may have included Common Barn-owl (*Tyto alba*) in past, though that species now considered extinct there; introduced threats may include rats and domestic and feral cats.

Bibliography. Appert (1996), Benson (1967b), Benson & Penny (1971), Benson *et al.* (1976-1977), Collin & Collin (1996), Dee (1986), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Goodman & Parrillo (1997), Goodman *et al.* (1997), Langrand (1995), Milon *et al.* (1973), Morris & Hawkins (1998), Mustoe *et al.* (1998), Penny (1974), Rand (1936), Safford & Duckworth (1990), Skerrett (1996), Young (1995).

69. Swamp Nightjar

Caprimulgus natalensis

French: Engoulevent du Natal **German:** Natalnachtschwalbe **Spanish:** Chotacabras del Natal
Other common names: African White-tailed Nightjar, Natal Nightjar

Taxonomy. *Caprimulgus natalensis* A. Smith, 1845, Durban.

Nominate incorporates possible races: *chadensis* (Sahel zone S to W Uganda); *gabonensis* (WC Africa); *fulviventris* (Angola); *curpi* (Caprivi Strip, Namibia); and *mpusa* (Zambia). Two subspecies currently recognized.

Subspecies and Distribution.

C. n. natalensis A. Smith, 1845 - very patchily from E Gambia to SW Ethiopia and S to E South Africa.

C. n. accrae Shelley, 1875 - coastal strip from NC Sierra Leone to W Cameroon.

Descriptive notes. 20-24 cm; 1 male 86.5 g, 1 female 65 g. Sexually dimorphic. Upperparts brown or greyish-brown, heavily spotted with large, irregularly shaped dark brown marks on wing-coverts, scapulars and tertials; indistinct pale buff or buff nuchal collar; white throat patch; underparts brown, heavily spotted buff or buffish-white, becoming buff barred brown on belly. Male has large white spot on four outermost primaries, and two outermost tail feathers extensively white; female has buffish or pale tawny wing spots and narrow buffish-white tips to tail feathers. Iris brown, bill dark brown, legs and feet pinkish-brown. Variable in coloration.

commonest forms being brown, greyish-brown or buffish-brown. Immature similar to adult but more spotted on upperparts. Race *accrae* darker, plainer and smaller. VOICE. Song of male is a monotonous "chop, chop, chop, chop" given from ground. Flight call is a rapid "chip, chip, chip, chip", courtship calls given by both sexes are "whip, whip, whip" or melodious "wip, lulululul" notes; other calls include soft "crup" and low "kik" notes.

Habitat. Mainly wet or damp habitats, sparsely vegetated with tufts or clumps of grasses, plants and other vegetation: grassland, meadows, swamps, marshes, bogs and dambos, marshy floodplains and vleis, and lagoon edges. Also along edges of woods and forest and in drier *Echinochloa* grassland. In W Africa, also damp grassy clearings in forest; in South Africa, frequently in areas with palms. Burnt habitats unsuitable, tends to vacate areas after fires. Recorded from sea-level to 2200 m.

Food and Feeding. Diet includes moths, termites, bugs and beetles. Foraging methods poorly documented, but recorded hunting around termite hills, pastures and cattle pens, often flying low over ground.

Breeding. Breeds from Mar in Sierra Leone, Apr-May in Nigeria, possibly mid-Aug to Oct in SE Gabon, Apr-Jun in W Kenya, Mar-May in NE Zaire, Aug-May in S Zaire, Jan-Mar, Jun-Aug and Oct in C & S Uganda, Sept-Nov in Zambia, and Aug-Nov in Angola, NW Zimbabwe and Natal. Monogamous. Nest-site often in long grass at edge of marsh or airstrip, or on sandy riverbank; no nest, eggs laid on bare soil, usually close to grass. Clutch usually 2 eggs, elliptical, slightly glossy, whitish, pinkish or pale grey with faint lilac patches and indistinctly spotted grey and speckled brown; both sexes incubate, female by day and male by night, period not more than 20 days (at one nest in Zimbabwe); chick covered in whitish down, dark grey on rump, though at Zimbabwe nest the chicks had dark grey/brown down; fledging period not documented.

Movements. Poorly known. Both races probably sedentary throughout much of range, although local movements may be triggered by loss of habitat, e.g. flooding after rains, or fire.

Status and Conservation. Not globally threatened. Rare in Gambia, though status uncertain; uncommon in Sierra Leone; widespread but mainly in coastal regions in Liberia; locally uncommon on Acra plains in Ghana; fairly common locally in Nigeria; rare on shores of L Chad but common in C Sudan (Nile Sudd), widely distributed but local in S. Locally common in N Congo, e.g. 4-5 pairs/km² in Odzala National Park; widespread and locally common in NE & S Zaire; fairly widespread and locally common in Uganda; uncommon to common locally in W Kenya; locally common between 600-2200 m in NW Tanzania; widespread and locally uncommon to frequent in N & W Zambia; locally common in region of Kazungula and upper Zambezi in Zimbabwe, with concentrations of up to 50 pairs in suitable habitat; locally fairly common in N Botswana; formerly widespread in Natal, South Africa, now locally uncommon to common; listed as vulnerable in South African Red Data Book. Throughout wide range, occurs in many protected areas, e.g. Ruwenzori National Park (Uganda), Ruvuvu National Park (Burundi) and Mkuzi Game Reserve (South Africa). Possibly locally common in suitable habitat throughout other parts of range. Major threats appear to be loss of habitat as a result of drainage, cultivation or fires, and damage from grazing and trampling by large herbivores. In Zimbabwe, effects of grassland burning unclear: might be favourable or detrimental to grass species required by present species; significance of different timing of burning could usefully be studied.

Bibliography. Anon. (1996b), Bannerman (1953), Barlow *et al.* (1997), Benson *et al.* (1971), Britton (1980), Brooke (1984), Cave & Macdonald (1955), Chapin (1939), Christy & Clarke (1994), Clancey (1996), Colebrook-Robjent (1979), Dowsett (1989a), Dowsett & Dowsett-Lemaire (1993, 1997), Dowsett & Forbes-Watson (1993), Elgood *et al.* (1994), Evans & Balmford (1992), Field (1998), Fry *et al.* (1988), Gatter (1997), Ginn *et al.* (1989), Grimes (1987), Harrison *et al.* (1997), Harwin (1983), Hustler (1997), Hustler & Carson (1996), Hustler & Mitchell (1997), Jackson (1986, 1987), Lewis & Pomeroy (1989), Lippens & Wille (1976), Louette (1981, 1990b), Mackworth-Præd & Grant (1957, 1962, 1970), Maclean (1993), Nikolaus (1987, 1989), Penry (1994), Pinto (1983), Rand (1951b), Randall (1988), Short *et al.* (1990), Snow (1978), Steyn (1996a), Zimmerman, D.A. (1972), Zimmerman, D.A. *et al.* (1996).

70. Plain Nightjar

Caprimulgus inornatus

French: Engoulevent terne **German:** Marmornachtschwalbe **Spanish:** Chotacabras Sencillo
Other common names: Ludovic's Nightjar (possible race *ludovicianus*)

Taxonomy. *Caprimulgus inornatus* Heuglin, 1869, Bogosland.

Possibly forms superspecies with *C. stellatus*. Birds from SW Ethiopia formerly separated as race *ludovicianus*, which was sometimes considered a separate species. Birds of Niger formerly separated as race *vinaceobrunneus*. Monotypic.

Distribution. S Mauritania and N Senegal E to Ethiopia, NW Somalia and NW Kenya, and SW Saudi Arabia S into Yemen. Winters from Senegal and Liberia to SW Sudan and possibly SW Ethiopia, and S to Tanzania.

Descriptive notes. 22-23 cm; male 33-61 g, female 32-57 g. Sexually dimorphic. Upperparts and wing-coverts very variable in colour, blackish-brown, brown, greyish-brown, vinaceous, rufous, pale tawny-buff or sandy-buff, rather plain, with blackish-brown streaking and spotting on head and scapulars, and wing-coverts occasionally spotted buffish; no nuchal collar; lacks obvious white throat patch; underparts brownish or buff, barred brown. Male has white spot on four outermost primaries and broad white tips to two outermost tail feathers; female has tawny wing spots and lacks white in tail. Iris dark brown, bill brown with black tip, legs and feet pale brown. Has somewhat longer tail than *C. stellatus* and lacks white throat patch; broader white tips to two outermost tail feathers. Immature similar to adult. VOICE. Song of male is a prolonged, evenly pitched churr, occasionally beginning with a long series of deep cuck notes. Possibly sings from ground. Gives soft chuckles in flight; calls include low "chuk" notes. Makes guttural hissing sounds during threat or defence displays.

Habitat. Mainly savanna with trees and bushes, semi-desert steppes, less dense areas in lush savanna woodland, and grassy forest clearings. Outside breeding season, mainly wooded savanna. In Saudi Arabia, typically barren lowlands inland of Asir Mts, but also rocky terrain at higher altitudes. In Yemen, juniper forest on Jabal Iraf and in Wadi Hadramawt region, also slopes of arid wadis. Recorded from sea-level to 1800 m.

Food and Feeding. Poorly documented. Diet includes moths, termites, ants, grasshoppers, antlions, crickets, mantises and beetles. Forages by making flycatching sallies from ground or by hawking for prey in prolonged, buoyant flights.

Breeding. Poorly known. Breeds Apr-Jun in Mali, May-Jun in Niger, Mar-Jun in Ethiopia, Dec to mid-Jun in Somalia, May-Aug in NW Kenya (though nesting Mt Elgon in Sept) and Mar-May in Nigeria; possibly May-Jun in Liberia, where occasionally breeds (though two juveniles Dec and Jan); no data from Saudi Arabia or Yemen. Possibly monogamous. No nest, eggs laid on bare soil, usually near or under small bush. Clutch usually 2 eggs, elliptical-ovate, glossy ivory-white or creamy, spotted and speckled red-brown and lilac; incubation period not documented; chick covered with pale buff down, fledging period not known.

Movements. In Middle East, possibly a breeding summer visitor only in SW Saudi Arabia and Yemen; vagrant recorded off Kuria Muria Is, near Oman coast. In Africa, a breeding visitor (Apr-Nov) to Sahelian savannas. After breeding, moves S into wooded savannas along edges of rain-forest zone, occasionally straying into forests. Winters from Senegal to Liberia, E to NE Zaire, SW Sudan and possibly SW Ethiopia, S through Uganda, Kenya and N Tanzania to SC & E Tanzania. Passage migrants common N Nigeria (May-Jun and Nov-Dec) and regular N & E Kenya (Oct-Dec and Mar-Apr). Occasionally breeds within wintering range (Enugu, Nigeria; Mt Nimba, Liberia; Mt Elgon, Kenya) and possibly resident at Lagos, Nigeria. Vagrants recorded Gabon (Feb and Jul).

Status and Conservation. Not globally threatened. In Saudi Arabia, thought to be a summer visitor in small numbers but possibly under-recorded; locally common in Yemen. Generally rather common throughout much of African range: common in S Mauritania; uncommon, possibly seasonal visitor, in Senegal and Gambia but perhaps under-recorded; possibly not uncommon from Mali eastwards; locally uncommon in Ethiopia; common in Eritrea; fairly common in NW Somalia; uncommon seasonal migrant in Ghana but fairly common in Togo; in Nigeria, possibly resident in S but elsewhere fairly common migrant during dry season only; common seasonal visitor in NE Zaire; fairly widespread and seasonally common, though generally considered fairly uncommon, in W, C & S Kenya. Occurs in a number of protected areas, e.g. W National Park (SW Niger), Kabalega Falls National Park (W Uganda), and Tsavo West and Tsavo East National Parks (Kenya).

Bibliography. Ash & Miskell (1983b, 1998), Bannerman (1953), Barlow *et al.* (1997), Britton (1980), Brooks *et al.* (1987), Brouwer (1992), Cave & Macdonald (1955), Chapin (1939), Cheke & Walsh (1996), Christy (1984), Colston & Curry-Lindahl (1986), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Dymond (1996a), Elgood, Fry & Dowsett (1973), Elgood, Heigham *et al.* (1994), Evans (1994), Field (1998), Fry (1985), Fry *et al.* (1988), Gatter (1997), Gee (1984), Giraudoux *et al.* (1988), Grant & Mackworth-Praed (1946), Grimes (1987), Hollom *et al.* (1988), Jennings (1995), Lewis & Pomeroy (1989), Lippens & Wille (1976), Louette (1981, 1990b), Mackworth-Praed & Grant (1957, 1970), Nikolaus (1987), Porter & Martins (1993), Porter, Christensen & Schiermacker-Hansen (1996), Porter, Martins *et al.* (1996), Rand (1951b), Short *et al.* (1990), Snow (1978), Symens *et al.* (1992), Urban & Brown (1971), Zimmerman, D.A. *et al.* (1996).

71. Star-spotted Nightjar

Caprimulgus stellatus

French: Engoulevent étoilé **German:** Sternnachtschwalbe **Spanish:** Chotacabras Estrellado

Taxonomy. *Caprimulgus stellatus* Blundell and Lovat, 1899, Kassim River, southern Ethiopia.

Possibly forms superspecies with *C. inornatus*. Birds from lake region of S Ethiopia formerly separated as race *simplex*. Monotypic.

Distribution. NW Somalia, Djibouti, C & S Ethiopia, SE Sudan and NW, N & C Kenya.

Descriptive notes. 21-23 cm; male 54-64 g, female 50-69 g. Sexes similar. Slight colour variation noted with individuals ranging from greyish or vinaceous brown to paler, sandy brown. Upperparts and wing-coverts rather plain, generally dark greyish-brown, minutely speckled dark brown; crown and scapulars sparsely streaked and spotted dark brown, spots star-shaped; no nuchal collar; small white patch on either side of lower throat; underparts paler than upperparts, often brownish or buff barred brown. Both sexes have white spot on four outermost primaries and narrow white tips to two outermost tail feathers.

Iris dark brown, bill blackish, legs and feet flesh brown. Differs from more variable *C. inornatus* by white on throat and narrower white tips to two outermost tail feathers in male. Immature similar to adult but upperparts plainer and often rather rufous. **Voice.** Song of male is a soft, yelping "pweu, pweu, pweu, pweu" or "pwe-eh, pwe-eh, pwe-eh", given from ground, mainly at dusk and dawn. Flight call is possibly a guttural "churr-krk".

Habitat. Largely confined to dry, open bush and grassland, but also stony semi-deserts and black lava fields with densely scattered boulders, rocks and stones. Recorded from sea-level to possibly 1980 m.

Food and Feeding. Diet poorly studied. Feeds on moths, mantises, beetles and grasshoppers. Foraging methods not documented.

Breeding. Almost completely unknown. Possibly breeds Jan-Mar throughout range.

Movements. None documented. Sedentary.

Status and Conservation. Not globally threatened. Locally common in Ethiopia, especially in S, e.g. possibly one of commonest nightjars in Nechisar National Park; rare in SE Sudan; locally common in NW & N Kenya, where occurs in Marsabit Nature Reserve. Probably not very common throughout remainder of E African range, but probably under-recorded.

Bibliography. Ash & Miskell (1998), Britton (1980), Cave & Macdonald (1955), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Duckworth *et al.* (1992), Fry (1988a), Fry *et al.* (1988), Lewis & Pomeroy (1989), Mackworth-Praed & Grant (1957), Nikolaus (1987, 1989), Safford *et al.* (1993), Short *et al.* (1990), Snow (1978), Tilahun *et al.* (1996), Urban & Brown (1971), Zimmerman, D.A. *et al.* (1996).

PLATE 34

inches 4

72. Savanna Nightjar

Caprimulgus affinis

French: Engoulevent affin **German:** Savannennachtschwalbe **Spanish:** Chotacabras de Sabana
Other common names: Allied Nightjar; Franklin's Nightjar (*monticolus* group)

Taxonomy. *Caprimulgus affinis* Horsfield, 1821, Java.

Races split into two distinct groups, formerly considered distinct species, but voice apparently identical: N populations, comprising first three races, form *monticolus* group; S populations, with remaining seven races, form *affinis* group. Birds from S Sulawesi may represent an undescribed taxon. Populations from NE India to Thailand formerly separated as race *burmanicus*. Ten subspecies currently recognized.

Subspecies and Distribution.

C. a. monticolus Franklin, 1831 - NE Pakistan and India E to Myanmar and S to Thailand, Cambodia and S Vietnam.

C. a. amoyensis Stuart Baker, 1931 - SE China and N Vietnam.

C. a. stictomus Swinhoe, 1863 - Taiwan.

C. a. griseatus Walden, 1875 - Luzon, Catanduanes, Mindoro, Sibuyan, Negros and Cebu (N Philippines).

C. a. mindanensis Mearns, 1905 - Mindanao (SE Philippines).

C. a. affinis Horsfield, 1821 - Sumatra, Borneo and Java, E to Lombok and possibly S Sulawesi.

C. a. propinquus Riley, 1918 - Sulawesi (possibly except Macassar region on S peninsula).

C. a. undulatus Mayr, 1944 - Sumbawa, Komodo and Flores (W Lesser Sundas).

C. a. kasudori Hachisuka, 1932 - Sawu and Sumba (C Lesser Sundas).

C. a. timorensis Mayr, 1944 - Alor, Timor, Roti and Kisar (E Lesser Sundas).

Descriptive notes. 20-26 cm; male 54-86 g, female 75-110 g. Sexually dimorphic. Upperparts brown, speckled whitish or cinnamon and streaked blackish-brown; pale buffish, cinnamon or whitish nuchal collar; lesser coverts brown speckled pale buff, rest of wing-coverts paler, boldly spotted pale buff; scapulars blackish-brown, broadly edged buff or whitish on outer webs; buffish submoustachial stripe and small white patch on either side of lower throat; underparts brown, barred, speckled and spotted buff and cinnamon, becoming buff barred brown on belly and flanks. Male has large white spot on four outermost primaries, and two outermost tail feathers are generally white, tipped or edged brownish; female has buffish wing spots and no white in tail. Iris dark brown, bill blackish, legs and feet brown. Less variegated than *C. asiaticus*, with narrower nuchal collar and weaker spotting on wing-coverts; male of that species often has smaller white wing spots, and two outermost tail feathers are broadly tipped white. Slightly smaller than *C. indicus*, with wing-coverts less heavily spotted and fewer white tips to tail feathers in male. Slightly smaller, greyer and less variegated than *C. macrurus*, of which male has white tips to two outermost tail feathers. Immature similar to adult female but paler, greyer-brown. Two distinct racial groups differ significantly in size and colour: racial variation within smaller, greyer S populations (*affinis* group) includes overall coloration, colour of markings on upperparts, and amount of white on wings and tail; racial differences within larger, browner N populations (*monticolus* group) concern coloration only. Voice. Call is a loud, repetitive "chrip" or "chweep", given mainly in flight. Occasionally calls from perches. Other calls include low chuckles and soft screeches.

Habitat. Mainly grassland, grassy plains and open woodland and forest, often with scrub or rocky outcrops; also arable land, stony or sparsely vegetated hillsides and barren ridges, edges of swamps and mangroves, sandy or shingly beaches, bare sand or riverbanks, dry stony riverbeds with growth of scrub and grass, coastal scrubland, and urban habitats, including cities. Recorded from sea-level to 1500 m, possibly to 2000 m.

Food and Feeding. Diet includes moths, mantises, beetles, termites and flying ants. Forages in flight, often high above ground, hawking after prey over forests, cultivated areas, cities, towns, villages, airports and golf courses. Also feeds on insects attracted to artificial lights. Drinks in flight. Large feeding flocks often occur, especially during migration.

Breeding. Breeds Jun-Jul in N Pakistan, Apr-Aug in India and Himalayas, May to perhaps Mar in Philippines, Mar-Dec in Java, and Apr-Jan in Sumatra. Nest-site in open, at base of tree, hidden among scrub or tufts of grass, or beneath bush; no nest, eggs laid on ground, often among stones. Clutch 1-2 eggs, elliptical, salmon-pink or pale buffish, spotted and blotched reddish-brown and deep red; both sexes incubate, period not documented; adults threatened at nest-site perform injury-feigning distraction display; chick nidicolous, not described, fledging period not documented.

Movements. Poorly known. S populations that form *affinis* group appear to be largely sedentary, though a vagrant (possibly nominate race) recorded on Christmas I in May and Oct 1994 and possibly Nov 1996. Race *monticolus* sedentary and locally migratory, e.g. in NE Pakistan apparently a summer breeding visitor only, arriving Mar-Apr and departing Oct-Nov, probably moving through Punjab plains. Race *amoyensis* possibly sedentary. Race *stictomus* possibly sedentary and partially migratory, as some thought to move SW after breeding season and winter in Laos and SE Thailand.

Status and Conservation. Not globally threatened. Locally common to common throughout its range. Abundant passage migrant and common breeding bird in N Pakistan; probably not uncommon in SE China; resident in Taiwan; uncommon to locally common in N & C Thailand; locally common throughout much of Wallacea, Philippines and lowlands of Borneo; common in lowlands of Sumatra, Java and Bali. Tolerant of wide range of habitats and apparently highly adaptable; often occurs in urban environments, e.g. in W Indonesia frequents towns and cities in several regions of Sumatra and Java. Occurs in many protected areas throughout wide range, e.g. Chitwan National Park (Nepal), Panti Forest Reserve (Malaysia), Baluran National Park (Java) and Bali Barat National Park.

73. Freckled Nightjar

Caprimulgus tristigma

French: Engoulevent pointillé **German:** Fleckennachtschwalbe **Spanish:** Chotacabras Pecosó
Other common names: West African Freckled Nightjar, Rock Nightjar

Taxonomy. *Caprimulgus tristigma* Rüppell, 1840, Gondar, Ethiopia.

Five subspecies recognized.

Subspecies and Distribution.

C. t. sharpei Alexander, 1901 - Guinea and N Sierra Leone E to W Nigeria, W Cameroon, N Equatorial Guinea and C Central African Republic.

C. t. pallidogriseus Parker & Benson, 1971 - Nigeria (perhaps on Jos Plateau).

C. t. tristigma Rüppell, 1840 - Ethiopia, S Sudan and NE Zaire S to Burundi and N Tanzania.

C. t. lentiginosus A. Smith, 1845 - W Angola, NW & WC Namibia and W South Africa.

C. t. granosus Clancey, 1965 - SE Zaire, Zambia and S Tanzania S to CN & E South Africa.

Descriptive notes. 26-28 cm; male 70-100 g, female 69-91 g. Sexually dimorphic. Upperparts and wing-coverts blackish-brown, profusely spotted and speckled white, pale buff and cinnamon, no nuchal collar; white throat patch; underparts dark brown barred whitish and cinnamon, becoming buff barred brown on belly. Male has small white spot on four outermost primaries and broad white tips to two outermost tail feathers; female has smaller white wing spots and lacks white in tail. Iris dark brown, bill blackish, legs and feet blackish. Immature similar to adult. Races vary slightly in size and tone of overall coloration. Voice.

Song of male is a variable "whow, whow, whow" or "ow-whow, ow-whow", although bursts of 4-5 notes may occasionally be given; also repetitive, ringing "wha" or "wa" sounds. Sings from rocks and occasionally other perches. Flight calls include "kheh, kheh, kheh" or a series of "wok" calls; if disturbed, utters "kluk, kluk, kluk" notes. Alarm call is a yelping gobble; adult gives soft, grumbling "gok, gok" calls during distraction displays; chick utters soft, mewing "wee-oo" sounds.

Habitat. Typically, rocky terrain with vegetation: outcrops, rocky or boulder-strewn hills, kopjes and inselbergs, ravines and wooded slopes on escarpments. Also bare hills within forest, on rocks alongside rivers and rapids, and more recently in built-up areas. Vacates burnt areas after fires. Outside breeding season, occasionally wanders away from rocky habitats. Recorded between 600 m and 2000 m.

Food and Feeding. Diet poorly studied. Feeds on moths, winged termites and beetles. Foraging methods not fully documented. Forages over rocks, rocky hillsides, open country and pastures; also hawks for insects around tree tops.

Breeding. Breeds Jan to perhaps May in Nigeria, May-Jun in Ethiopia, Kenya and NE Zaire, late Aug to Nov in Rwanda, Burundi, Tanzania, Zambia and Malawi, Aug-Dec in Zimbabwe, and Sept-Nov in South Africa and possibly S Mozambique. Possibly double-brooded, second clutch laid shortly after first brood fledges. Monogamous; territorial. Nest-site often near patches of lichen, in open or partly shaded, same site often used for several years; no nest, eggs laid usually on vegetation or leaf litter in depression or shallow hollow on rock, more recently also on flat rooftop (Durban, South Africa). Clutch usually 2 eggs, elliptical, whitish, streaked, speckled and blotched black, grey or light brown on underlying pale lilac, laid on successive days; incubation commences with first egg, is usually by female during day, period c. 17-19 days; adults threatened at nest-site give distraction display; chick semi-precocial, covered in mottled dark grey and off-white down, fed by regurgitation; young brooded for c. 12 days, fledge at c. 20 days.

Movements. Poorly known. Although appears to be mainly sedentary, some populations may undertake local movements in cold winters (e.g. at Matopos, Zimbabwe). Possibly migratory in Nigeria. No other information available.

Status and Conservation. Not globally threatened. Fairly common throughout much of range and locally abundant in some countries or regions. Uncommon and local in Ghana; locally fairly common in Togo; locally common in Nigeria in suitable habitat; extremely local but fairly common where it occurs in S Sudan; fairly common and locally abundant in Ethiopia. Local and possibly not particularly common in NE & SE Zaire; local in Uganda; locally uncommon to common in Kenya, though probably under-recorded; rather common locally in Zambia; fairly common in Malawi; widespread and locally very common in Zimbabwe; sparsely distributed and generally uncommon in N & E Botswana; locally common to very common in South Africa. Possibly more widespread than currently known. Occurs in several protected areas, e.g. Gashaka-Gumti Reserve (Nigeria), Tsavo West and Tsavo East National Parks and Marsabit Nature Reserve (Kenya), Akagera National Park (Rwanda) and Hwange National Park (Zimbabwe).

Bibliography. Bannerman (1953), Benson & Benson (1977), Benson & Pitman (1959), Benson *et al.* (1971), Britton (1980), Brouwer & Mullié (1992), Cave & Macdonald (1955), Cheke & Walsh (1996), Christy & Clarke (1994), Clancey (1957, 1972, 1996), Colebrook-Robjent (1979, 1984), Colston & Curry-Lindahl (1986), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Elgood (1972), Elgood *et al.* (1994), Field (1998), Fry *et al.* (1988), Gatter (1997), Ginn *et al.* (1989), Grimes (1987), Harrison *et al.* (1997), Hockey *et al.* (1989), Jackson (1971, 1973a, 1975, 1978, 1983, 1984a, 1986, 1987), Lewis & Pomeroy (1989), Lippens & Wille (1976), Louette (1981, 1990b), Mackworth-Præd & Grant (1957, 1962, 1970), Maclean (1993), Markus (1973), Masterson (1992), Nikolaus (1987, 1989), Parker & Benson (1971), Penny (1994), Pinto (1983), Rossouw & Cooper (1993), Short *et al.* (1990), Snow (1978), Steyn (1971, 1996a, 1996b), Urban & Brown (1971), Zimmermann, D.A. *et al.* (1996).

74. Bonaparte's Nightjar

Caprimulgus concretus

French: Engoulevent de Bonaparte

German: Sundanachtschwalbe

Spanish: Chotacabras de Bonaparte

Taxonomy. *Caprimulgus concretus* Bonaparte, 1850, Ashanti; error = Borneo. Monotypic.

Distribution. Sumatra, Belitung I and Borneo.

Descriptive notes. 21-22 cm. Sexually dimorphic. Upperparts brown spotted chestnut, no nuchal collar; wing-coverts brown, spotted chestnut and cinnamon; scapulars blackish-brown tipped chestnut, broadly edged pale buff on outer webs; white submoustachial stripe and large white throat patch; underparts brown barred chestnut, becoming buff barred brown on belly and flanks. Both sexes lack white on wings; male has white tips to two outermost tail feathers, female rarely having very narrow white tips. Iris dark brown, bill brownish, legs and feet brown. Paler and less heavily spotted than *C. pulchellus*, of which male has small white marks on four outermost primaries and white tips to two outermost tail feathers. Immature plumages unknown. Voice. Song of male is a low, mournful "wa-ouuuu", second note descending in pitch. Sings from perches, mainly at dusk and dawn and on moonlit nights.

Habitat. Mainly lowland forest: dipterocarp forest, heath forest and secondary growth, from sea-level to 500 m. One old record from cleared land in lowlands.

Food and Feeding. Diet poorly studied; probably feeds on insects. Foraging methods not fully documented. Forages by making short flycatching sallies from perches, often hunting out over rivers.

Breeding. No information.

Movements. None documented. Sedentary.

Status and Conservation. Not globally threatened. Currently considered Near-threatened. Although apparently widely distributed, species is possibly rare and under-recorded throughout its range. In Sumatra, no records since 1916 until several birds heard and seen in Way Kambas National Park in early Aug 1995. In Malaysian parts of Borneo: few recent records from Sarawak; only single record from Sabah, from 19th century.

Bibliography. Andrew (1992), Holmes (1996, 1997), Holmes & Burton (1987), MacKinnon & Philipps (1993), van Marle & Voous (1988), Marshall (1978), Parrott & Andrew (1996), Smythies (1981), Vowles & Vowles (1984), Yong (1997).

75. Salvadori's Nightjar

Caprimulgus pulchellus

French: Engoulevent de Salvadori

German: Salvadorinachtschwalbe

Spanish: Chotacabras de Salvadori

Taxonomy. *Caprimulgus pulchellus* Salvadori, 1879, Mount Singalan, Sumatra.

Races occasionally considered two separate species, and taxonomic status requires further study. Two subspecies currently recognized.

Subspecies and Distribution.

C. p. pulchellus Salvadori, 1879 - Sumatra.

C. p. bartelsi Finsch, 1902 - Java.

Descriptive notes. 19-21.5 cm. Sexually dimorphic, though not greatly so. Upperparts and wing-coverts dark brown, spotted and barred tawny, cinnamon and buff; crown and nape paler, greyer-brown, central feathers broadly streaked blackish; indistinct tawny-buff nuchal collar; tawny submoustachial stripe and large white patch on either side of lower throat; underparts tawny, buff and greyish-white, barred brown, becoming buff barred brown on lower belly, flanks and undertail-coverts. Male has small white spot or bar on second to fifth outermost primaries and white tips to two outermost tail feathers; female has tawny wing spots

and white or buff tips to two outermost tail feathers. Iris brown, bill blackish, tarsus brownish. Darker and more heavily spotted than *C. concretus*, which lacks white on wings in both sexes; race of that species has white tips to two outermost tail feathers. Immature plumages unknown. Race *bartelsi* rather similar but perhaps averages smaller; lacks nuchal collar, and has different scheme of coloration on upperparts. Voice. Song of male is possibly a short series of "tok" notes.

Habitat. Typically montane and submontane forest, often on cliffs and cliff faces; also occasionally in small marshy areas. Recorded between 800m and 2100 m.

Food and Feeding. Poorly studied. Probably feeds on insects; forages over forest clearings or near cliffs. When hunting, flies slowly with flapping wingbeats and frequent glides. Also makes short flycatching sallies from perches, or takes prey from cliff faces.

Breeding. Poorly known. Breeds late Mar to May in Java; season in Sumatra undocumented. Nest-site recorded under tea bush; no nest, eggs laid on leaf litter on ground. Clutch 1-2 eggs, elliptical, glossy white and unmarked.

Movements. None documented. Sedentary.

Status and Conservation. Not globally threatened. Data-deficient. Restricted-range species: present in Sumatra and Peninsular Malaysia EBA and Java and Bali Forests EBA. Although not currently listed as threatened, this poorly known species requires further study, especially in Sumatra. Only confirmed records from Sumatra are apparently the type specimen (a male), taken from Mt Singalang in Jul 1878, and another male taken from Gunung Dempo in Jul 1936, with sight records in Jun 1989 and Jul 1993. In Java, rare and little known, although a small population is known to exist in Gunung-Gede-Pangrango National Park.

76. Prigogine's Nightjar

Caprimulgus prigoginei

French: Engoulevent de Prigogine

German: Prigoginenachtschwalbe

Spanish: Chotacabras de Prigogine

Other common names: Itombwe Nightjar

Taxonomy. *Caprimulgus prigoginei* Louette, 1990, Malenge, Itombwe, Kivu Province, Zaire. Monotypic.

Distribution. E Zaire.

Descriptive notes. 19 cm. Known only from a single specimen, a female. Upperparts and wing-coverts brown, speckled and spotted dark brown, tawny and buff, no nuchal collar; breast brown spotted and barred tawny and buff; belly and flanks paler, barred brown; small tawny spot on second, third and fourth outermost primaries; narrow whitish tips to outermost tail feathers, narrower buffish or tawny tips to remainder. Iris not described, bill blackish, legs and feet reddish-brown. Voice. Unknown.

Habitat. Unknown, though probably a forest species. The single specimen is from 1280 m.

Food and Feeding. Probably feeds on insects.

Foraging methods unknown.

Breeding. Unknown.

Movements. Unknown.

Status and Conservation. VULNERABLE. Restricted-range species: present in Albertine Rift Mountains EBA. Currently known only from type specimen, a female, taken at Malenge, Itombwe, in Kivu Province, E Zaire in Aug 1955. Deforestation is a potential threat to this little-known species, although unidentified nightjars continue to be seen and heard in vicinity of type locality, and are also being reported from forests in other parts of Africa.

Bibliography. Collar *et al.* (1994), Curry-Lindahl (1960), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Dowsett-Lemaire & Dowsett (1998a), Louette (1990a), Stattersfield *et al.* (1998), Vuilleumier *et al.* (1992).

77. Collared Nightjar

Caprimulgus enarratus

French: Engoulevent à nuque rose

German: Halsband-Nachtschwalbe

Spanish: Chotacabras Acollarado

Taxonomy. *Caprimulgus enarratus* G. R. Gray, 1871, Madagascar.

Monotypic.

Distribution. Madagascar.

Descriptive notes. 24 cm; 1 female 54 g. Sexes similar. Upperparts greyish-brown boldly spotted blackish-brown, spots edged chestnut; broad rufous nuchal collar with thin, well-defined buff band above; wing-coverts greyish-brown boldly spotted blackish-brown, spots broadly edged chestnut or pale buff; scapulars greyish-brown, boldly spotted blackish-brown with chestnut edges; tawny-buff band around lower throat; underparts generally brownish, boldly spotted blackish-brown edged chestnut, becoming less spotted and more streaked on belly and flanks. Both sexes lack white markings on wings and have narrow white tips to one or two outermost tail feathers. Iris dark brown, bill blackish or pinkish-grey with black tip, legs and feet dark brown or pinkish-grey. Darker and plainer than *C. madagascariensis*, which usually has no or indistinct tawny-buff nuchal collar; male of that species has white spot on four outermost primaries and broad white tips to two outermost tail feathers. Juvenile of present species paler and buffier than adult, with dark collar around hindneck and row of large blackish spots across wing-coverts. Voice. Song of male unknown. Alarm calls of adult at nest are repetitive, liquid "kow" or "keow" notes; adult makes guttural hissing sounds during threat/defence displays; chick utters soft "chic" notes.

Habitat. Mainly lowland primary forest, including dense, humid, evergreen forest; also adjacent second-growth forest and occasionally dry, deciduous forest. Recently recorded in brush forest and mangroves in W Madagascar. Occurs from sea-level to 1880 m.

Food and Feeding. Poorly studied. Probably feeds mainly on insects. Forages by hawking for prey both above and below forest canopy. Also recorded flycatching from exposed perch c. 20 m above ground in clearing at edge of forest, with short foraging flights covering up to 10 m; one bout of flycatching lasted up to 15 minutes.

Breeding. Poorly known. Breeds late Sept to early Dec (mainly Oct-Nov). Nest-site usually at edge of forest track or clearing; no nest, eggs laid possibly on leaf litter on ground, or on epiphytic ferns (*Asplenium*) on tree trunk up to c. 1.7 m above ground, or to c. 1.5 m up in crown of free-standing ferns. Clutch 2 eggs, glossy white and often lightly washed pinkish-brown; incubation period not known; adults threatened at nest-site may give defence display or injury-feigning distraction display; chick covered with down but not further described, fledging period not known.

Movements. No movements documented. Probably sedentary.

Status and Conservation. Not globally threatened. Generally considered rather rare throughout much of range, though usually secretive and difficult to observe, so possibly under-recorded and locally uncommon to fairly common in some regions. Recorded from vicinity of Antananarivo, E Imerina, Fanovana, Sihanaka Forest, Nosibey-Foule Point, Cap Masoala, Andapa, Maroantsetra, Perinet-Analamazaotra, Ranomafana, Andohahela, Montagne d'Ambre, Ankarana, Tsaratanana, Anaborano, Sambirano and Manombo; may also occur in other areas such as Fort-Dauphin, Baly Bay and Morondava. Threats include hunting by local people and loss of habitat as a result of deforestation, although many sites where it occurs are now protected, e.g. Andohahela, Ankarafantsika and Tsaratanana Integral Nature Reserves, Marojejy Nature Reserve, and Perinet-Analamazaotra Special Reserve.

Bibliography. Benson *et al.* (1976-1977), Chittenden (1996), Dee (1986), Dhondt (1976), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Evans (1993), Goodman & Parrillo (1997), Goodman *et al.* (1997), Langrand (1995), Milon *et al.* (1973), Morris & Hawkins (1998), Rand (1936), Roxby (1998), Safford & Duckworth (1990).

78. Bates's Nightjar *Caprimulgus batesi*

French: Engoulevent de Bates **German:** Waldnachtschwalbe **Spanish:** Chotacabras de Bates
Other common names: (Bates's) Forest Nightjar

Taxonomy. *Caprimulgus batesi* Sharpe, 1906, River Dja, Cameroon.
Monotypic.

Distribution. W & S Cameroon, NE Gabon and W & NE Congo through SW Central African Republic and parts of Zaire to W Uganda.

Descriptive notes. 29-31 cm; (unsexed) 89-112 g. Sexually dimorphic. Upperparts and wing-coverts dark brown, broadly streaked, spotted and speckled blackish-brown, buff and tawny; buff or tawny nuchal collar; white throat patch; underparts blackish-brown, speckled buff on breast, becoming buff barred brown on belly. Male has small white spot on four outermost primaries and white tips to two outermost tail feathers; female is paler and lacks white markings on tail, those on wings being much duller. Iris, bill, legs and feet all dark brown. Immature similar to adult but paler and more buffish. **VOICE.** Song of male is a loud "whow, whow,

whow, whow", given from perches and occasionally ground. Flight call is a low "wuh wuh". **Habitat.** Mainly lowland primary rainforest, in clearings and along forest edges; also thick secondary forest, and plantations close to forest edges. Often near water and especially in flooded forest, where can be quite common in places.

Food and Feeding. Diet includes mantises, crickets, grasshoppers, beetles, moths and ants. Foraging methods poorly documented. Forages above and among forest canopy, along forest edges and over grassy plains.

Breeding. Poorly known. Breeds Dec-Jan in Gabon, Feb-Mar (possibly Nov-Jul) in Cameroon, and possibly all year in Zaire (Haut Zaire birds in breeding condition Mar-Oct, Lukokela egg Oct, Barumba chick Jul, and Evenaar juvenile Oct). Territorial. Nest-site on forest path or track, on sparsely vegetated ground, or along edge of thick forest, plantation or garden; no nest, egg laid on bare soil or leaf litter. Clutch 1 egg, elliptical, glossy white or pale pink, heavily blotched and mottled brown and lavender-grey; incubation period not known; chick covered in yellowish-buff down, fledging period not known.

Movements. None documented. Sedentary.

Status and Conservation. Not globally threatened. Considered potential candidate for listing as threatened species. Possibly locally common in rainforests throughout range. Locally common in N Congo; widely distributed but possibly rather rare in Cameroon, though present in protected areas such as Korup National Park; widely distributed in forested regions in Zaire. Territory size possibly up to c. 20 ha. Potential threat probably loss of habitat as a result of deforestation.

Bibliography. Bannerman (1953), Britton (1980), Brosset & Éard (1986), Carroll (1988), Carter & Colebrook-Robjent (1983), Christy & Clarke (1994), Dowsett & Dowsett-Lemaire (1991, 1993, 1997), Dowsett & Forbes-Watson (1993), Dowsett-Lemaire *et al.* (1993), Fry *et al.* (1988), Lippens & Wille (1976), Louette (1981, 1990b), Mackworth-Praed & Grant (1970), Rodewald *et al.* (1994), Sargeant (1993), Short *et al.* (1990), Snow (1978).

79. Long-tailed Nightjar *Caprimulgus climacurus*

French: Engoulevent à longue queue **German:** Schleppennachtschwalbe **Spanish:** Chotacabras Rabudo
Other common names: Slender-tailed Nightjar(!)

Taxonomy. *Caprimulgus climacurus* Vieillot, 1825, Senegal.

Forms superspecies with *C. clarus* and *C. fossii*, and all three have frequently been separated in genus *Scotornis*. Dark, dull-coloured birds from Sierra Leone to S Nigeria sometimes treated as separate race *leanini*, but possibly intermediate between nominate and race *sclateri*, or variant of latter. Three subspecies currently recognized.

Subspecies and Distribution.

C. c. climacurus Vieillot, 1825 - Mauritania E to W Ethiopia (except White Nile in S Sudan) and S to N & SE Zaire.

C. c. sclateri (Bates, 1927) - humid belt of W Africa (boundaries between races unclear).

C. c. nigricans (Salvadori, 1868) - White Nile in Sudan, from Kosti S to Shambe and L Nyubor; also along Bahr el Zeraf and Sobat R.

Descriptive notes. 28-43 cm; male 39-58 g, female 35-61 g. Sexually dimorphic. Variable in colour ranging from pale brown, brown and greyish-brown to sandy-buff. Upperparts and wing-coverts generally greyish-brown, finely streaked brown; male has white line across forewing, female having buff or buffish-white line; broad tawny or buff nuchal collar; white throat patch; underparts pale brown, speckled and barred pale buff, becoming buff thinly barred brown on belly and flanks. Male has broad white band across five outermost primaries and white trailing edge to inner wing, tail graduated, central pair longest, outer tail feathers edged and tipped white; female has buffish-white wing band and buff or buffish-white trailing edge to inner wing, and is shorter-tailed with outer feathers edged and tipped buff. Iris brown, bill brown, legs and feet brownish. Has notably longer tail than *C. clarus* and *C. fossii*, and is generally paler. Immature similar to adult female but paler. Race *nigricans* distinctive, generally blackish, male often longer-tailed; race *sclateri* more rufous, but variable in colour. **VOICE.** Song of male is a

long, evenly pitched churr, often ending with series of "chong" or "chiow" notes; sings from perches and ground. Calls include short series of "chong" or "chak" notes; makes guttural hissing sounds during threat/defence displays.

Habitat. Highly variable throughout range, in all habitats from arid semi-deserts to woods, forest and forest clearings; also commonly in all types of grassland and in cultivated areas. Also recently burnt areas and open patches in second growth and villages in Liberia. Outside breeding season, also stony hillsides and papyrus swamps.

Food and Feeding. Diet includes beetles, moths, mantises, bugs, ants, winged termites and grasshoppers. Foraging methods poorly studied. Forages in flight, hunting over open country, cultivated areas and among trees and bushes. Drinks in flight.

Breeding. Surprisingly poorly documented. Breeds Mar-Sept in N Senegal and possibly also Gambia, Mar-Aug in Mali and N Nigeria. Jan to perhaps Oct in S Nigeria. Feb-May in Sierra Leone, Jan-Dec in Ghana, possibly Feb-Aug in Togo, Mar-Jul in Uganda, Mar-Jun in N Zaire and Aug-Nov in SE Zaire. Probably monogamous. No nest, eggs laid on leaf litter or bare earth, often on or alongside path or track, in copse or cultivated field. Clutch usually 2 eggs, elliptical, creamy-white, buff or pinkish, heavily blotched grey or greyish-purple and stained amber; incubation and fledging periods not documented; downy chick not described.

Movements. Poorly known. Nominally race migratory and partially sedentary, some populations moving S after breeding season. Race *sclateri* possibly sedentary and partially migratory. Race *nigricans* probably sedentary. Outside breeding season, range also includes S Ivory Coast, SW Nigeria, S Cameroon, Equatorial Guinea, Gabon, SE Congo (lower Congo river valley), NE Angola (one record Luaco), SE Sudan, SW Ethiopia, W Kenya (sporadic in Turkana and Pokot region) and E Uganda.

Status and Conservation. Not globally threatened. Common and locally abundant throughout much of range, perhaps less so in forest clearings in S. Widespread and often rather common in Senegal; locally common in Gambia; common in Ghana and Togo; fairly common breeding visitor to Niger; Locally abundant on S shores of L Chad; widespread and common in Nigeria, numbers in S swollen by N migrants Nov-Feb; common and widely distributed throughout much of Sudan. Common in N Congo; widely distributed in Zaire; rare to scarce locally in Kenya. Occurs in several protected areas, e.g. Djoudj and Niokola Koba National Parks (Senegal), W National Park (Niger) and Waza National Park (Cameroon).

Bibliography. Bannerman (1953), Barlow *et al.* (1997), Bates (1927), Britton (1980), Brouwer (1992), Brown & Britton (1980), Cave & Macdonald (1955), Chapin (1939), Cheke & Walsh (1996), Colston & Curry-Lindahl (1986), Demy & Fishpool (1991), Dowsett & Dowsett-Lemaire (1993, 1997), Dowsett & Forbes-Watson (1993), Elgood, Fry & Dowsett (1973), Elgood, Heigham *et al.* (1994), Field (1998), Fry (1988a), Fry *et al.* (1988), Gatter (1997), Giraudoux *et al.* (1988), Gore (1990), Grimes (1987), Herremans & Stevens (1983), Jensen & Kirkeby (1980), Lewis & Pomeroy (1989), Lippens & Wille (1976), Louette (1981, 1990b), Mackworth-Praed & Grant (1957, 1970), Morel & Morel (1990), Newby (1980), Nikolaus (1987, 1989), Pinto (1983), Pitman (1930a, 1930b), Rand (1951b), Short *et al.* (1990), Smith (1957), Snow (1978), Tye (1984), Urban & Brown (1971), Zimmerman, D.A. *et al.* (1996).

80. Slender-tailed Nightjar *Caprimulgus clarus*

French: Engoulevent de Reichenow **Spanish:** Chotacabras Colifino
German: Kurzschleppen-Nachtschwalbe
Other common names: Reichenow's Nightjar

Taxonomy. *Caprimulgus clarus* Reichenow, 1892, Bukoba Tanzania.

Formerly considered conspecific with *C. fossii*, and these two form superspecies with *C. climacurus*; all three have frequently been separated in genus *Scotornis*. N populations formerly awarded separate race, *apatilis*. Monotypic.

Distribution. Djibouti, Ethiopia and SE Sudan S to Tanzania.

Descriptive notes. 28 cm; male 36-49 g, female 34-53 g. Sexually dimorphic. Slight colour variation with dark brown, blackish or buffish individuals noted. Upperparts and wing-coverts generally greyish-brown streaked dark brown; male has white line across forewing, female has buffish line; broad tawny or buff nuchal collar; white throat patch; underparts light brown, speckled and barred pale buff, becoming buff thinly barred brown on belly and flanks. Male has broad white band across six outermost primaries and white trailing edge to inner wing, tail graduated and wedge-shaped, central feathers longest, outer

feathers edged and tipped white; female has narrower white wing bands, buff or buffish-white trailing edge to inner wing, and tail less graduated with outer feathers edged and tipped buff. Iris brown, bill brown with black tip, legs and feet brownish. Has much shorter tail than *C. climacurus*, which is more variable in colour. Paler and greyer than *C. fossii*, with weaker streaking on crown, and longer tail much more graduated. Immature similar to adult female but paler. **VOICE.** Song of male is a long series of rapid "wa, wa, wa, wa, wa" notes, perhaps forming a slow churr, occasionally interspersed with high-pitched "wee" calls and ending with "chor-chor" or bubbling notes. Sings from ground or occasionally from perches. Flight call is a treble-noted "whit, whit, whit".

Habitat. Mainly thorny bush country, acacia scrub, sparsely wooded grassland, thinly vegetated scrubland, and open woodland, from sea-level to 2000 m.

Food and Feeding. Diet includes moths, flies, beetles, ants, bugs and Orthoptera. Foraging methods poorly studied. Forages by hawking for prey low over open ground, grasslands and rocky slopes. Also feeds on insects attracted to artificial lights.

Breeding. Poorly documented. Generally breeds Feb-May throughout range, N populations possibly beginning earlier, e.g. Feb-Mar in Ethiopia, Mar-Apr (also Jun-Aug) in Uganda, and Apr-May (also Nov) in Kenya. Possibly monogamous. No nest, eggs laid on bare soil, usually near or below small bush, occasionally near rock or stone. Clutch usually 2 eggs, elliptical, creamy or pinkish, blotched brown and faintly marked greyish-lilac; incubation period not known; adults threatened at nest-site may perform injury-feigning display; downy chick not described, fledging period not known.

Movements. Poorly known. Possibly sedentary throughout much of range, although in Somalia may be locally migratory according to rains.

Status and Conservation. Not globally threatened. Common to locally abundant throughout range. Common to abundant in Ethiopia, especially in S; locally abundant in S Somalia; widely distributed and locally common to abundant in SE Sudan, Uganda, Kenya and NE Tanzania. Occurs in several

ers edged and tipped white; female has buffish-white wing band and buff or buffish-white trailing edge to inner wing, and is shorter-tailed with outer feathers edged and tipped buff. Iris brown, bill brown, legs and feet brownish. Has notably longer tail than *C. clarus* and *C. fossii*, and is generally paler. Immature similar to adult female but paler. Race *nigricans* distinctive, generally blackish, male often longer-tailed; race *sclateri* more rufous, but variable in colour. **VOICE.** Song of male is a

protected areas, e.g. Awash National Park (Ethiopia), Samburu and Masai Mara Reserves (Kenya) and Tarangire National Park (Tanzania).

Bibliography. Archer & Godman (1937-1961), Ash & Miskell (1983b, 1998), Britton (1980), Brown & Britton (1980), Cave & Macdonald (1955), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Duckworth *et al.* (1992), Friedmann (1930), Fry *et al.* (1988), Lewis & Pomeroy (1989), Louette (1990b), Mackworth-Praed & Grant (1957), Nikolaus (1987, 1989), Peters & Loveridge (1936), Schels & Lavoyer (1987), Short *et al.* (1990), Snow (1978), van Someren (1956), Urban & Brown (1971), Wilson & Wilson (1994), Zimmerman, D.A. *et al.* (1996).

81. Mozambique Nightjar

Caprimulgus fossii

French: Engoulevent du Mozambique

German: Weltschnachtschwalbe

Spanish: Chotacabras de Fosse

Other common names: Gabon/Gaboon/Square-tailed Nightjar

Taxonomy. *Caprimulgus Fossii* Hartlaub, 1857, Gabon.

Formerly considered conspecific with *C. clarus*, and these two form superspecies with *C. climacurus*; all three have frequently been separated in genus *Scotornis*. In past, birds of coastal E Africa sometimes placed in race *mossambicus*. Three subspecies currently recognized.

Subspecies and Distribution.

C. f. fossii Hartlaub, 1857 - N & SW Gabon, and possibly SW Congo.

C. f. welwitschii Bocage, 1867 - S Zaire, S Burundi and S Tanzania S to N Namibia, N & E Botswana and NE South Africa.

C. f. griseoplurus Clancey, 1965 - Kalahari Desert and extreme N South Africa.

Non-breeding visitor N to N Zaire, Uganda and S Kenya.

Descriptive notes. 23-24 cm; male 54-68 g, female 47-77 g. Sexually dimorphic. Upperparts generally dark greyish-brown, heavily speckled greyish-white; broad buff or tawny-buff nuchal collar; wing-coverts dark greyish-brown, speckled and spotted greyish-white and pale buff; male has white, occasionally buffish, band across forewing, female has buff band; scapulars blackish-brown, broadly edged buff on outer webs; prominent buffish-white submoustachial stripe and white throat patch; underparts dark greyish-brown, speckled and spotted buffish-white or buff, becoming buff barred brown on belly and flanks. Male has

broad white band across five outermost primaries, white trailing edge to inner wing, and outermost tail feathers broadly edged and tipped white; female has narrower, whitish wing bands, buff trailing edge to inner wing, and outermost tail feathers broadly edged and tipped buff. Iris brown, bill blackish, legs and feet fleshy-brown or blackish. Darker and browner than *C. clarus*, with heavier streaking on crown, and a less graduated tail. Has much shorter tail than *C. climacurus*, which is more variable in colour. Immature similar to adult female but paler and plainer. Race *welwitschii* is

generally larger with heavier spotting on wing-coverts, and variable in colour, ranging from buffish-brown to blackish-brown. Race *griseoplurus* is larger, greyer and paler. **VOICE.** Song of male is a distinctive churr that rises in pitch and then levels off, occasionally ending with a single "wow" note. Sings from ground and occasionally perches. Calls include series of short "a-whoow" notes in flight, "whit, joe" while perched, and a rapid "shwip-ip-ip-ip" when alarmed; male makes guttural hissing or growling sounds during territorial encounters with other males; adults and chicks make guttural hissing sounds during threat/defence displays.

Habitat. Mainly open woodland or scrub, wooded grassland, and sandy country near water: mopane woodland and scrubland, open miombo woodland, riverine forest, wooded suburban gardens and thorny bush country. Also woodland edges, wooded hillsides, edges of cultivated land, urban gardens, plantations, teak forest, stony hillsides with scattered vegetation, burnt vleis, treeless dambos, savanna, swamps, trampled reedbeds, and lower slopes of kopjes. Recorded from sea-level to 1850 m.

Food and Feeding. Diet includes moths, beetles, grasshoppers, winged termites, ants and bugs. Forages by hawking for prey low over ground or water. Also makes short flycatching sallies from ground or perches, and may feed on insects attracted to or disturbed by fires.

Breeding. Breeds Jun on Pemba I, Oct on Zanzibar, Sept-Dec in S Burundi, S Tanzania and Mozambique, Sept-Nov in Malawi, Zambia and Zimbabwe, Oct-Jan in S Zaire, Aug-Oct in Angola, and Sept-Dec in Botswana and South Africa. Possibly single-brooded. Monogamous; probably territorial. Nest-site often among bushes or scattered clumps of grass, on burnt ground or near water, also on slope of kopje; no nest, eggs laid on leaf litter, bare soil, sand or gravel. Clutch 1-2 eggs, elliptical, matt or glossy, creamy-pink, blotched and smeared brown, finely speckled grey and lilac-grey, markings denser around blunt end; lays replacement clutch if first is lost; incubation mainly by female, period generally 14-17 days; chick semi-precocial, covered in dark brown and buffish down; adults threatened at nest-site may perform distraction display; fledging period not documented.

Movements. N nominate race probably sedentary. Race *welwitschii* possibly sedentary in parts of range, partially migratory in others, as only a breeding visitor to central plateau of Zimbabwe and parts of NE South Africa. As a non-breeding (winter) visitor, occurs in N Zaire, N Burundi, Rwanda, S & W Uganda, S Kenya and N Tanzania. Possible vagrant to S Botswana and C South Africa. Race *griseoplurus* also sedentary and partially migratory; occurs as a non-breeding (winter) visitor to Angola and Zambia, and as a possible vagrant to N Zimbabwe. Vagrants of unidentified race recorded in N Ivory Coast and S Ghana.

Status and Conservation. Not globally threatened. Very common to locally abundant throughout much of range. Locally common (perhaps seasonally) in S Kenya; widespread and common in S Zaire, C & S Tanzania, Zanzibar and Pemba. Widespread and common in Angola; locally abundant in Zambia; very common in Malawi, though less so above 650 m; generally very common in Mozambique; common throughout much of Zimbabwe, though less so Jun-Sept; common in N Namibia; common but sparsely distributed in Botswana, perhaps mainly in N & E; common in lowlands of NE South Africa, less common at higher altitudes. Occurs in a number of protected areas, e.g. Ruvuvu National Park (Burundi), Liwonde National Park (Malawi) and Kafue National Park (Zambia). Status of *griseoplurus* uncertain; recent surveys could not locate these populations in Kalahari.

Bibliography. Bannerman (1953), Benson & Benson (1977), Benson *et al.* (1971), Britton (1980), Brown & Britton (1980), Clancey (1965, 1996), Colebrook-Robjent (1979, 1984), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fry *et al.* (1988), Ginn *et al.* (1989), Hanmer (1996), Harrison *et al.* (1997), Jackson (1971, 1975, 1978, 1983, 1984a, 1986, 1987), Lewis & Pomeroy (1989), Lippens & Wille (1976), Louette (1990b), Mackworth-Praed & Grant (1957, 1962, 1970), Maclean (1993), Pakenham (1979), Penry (1994), Pinto (1983), Short *et al.* (1990), Snow (1978), Steyn (1996a, 1996b), Tree (1992), Zimmerman, D.A. *et al.* (1996).

ssp torquata

ssp furcifera

Genus *MACRODIPTERYX* Swainson, 1837

82. Standard-winged Nightjar

Macrodipteryx longipennis

French: Engoulevent à balanciers

Spanish: Chotacabras Portaestandard

German: Fahnennachtschwalbe

Taxonomy. *Caprimulgus longipennis* Shaw, 1796. Sierra Leone.

Genus formerly considered monotypic, with *M. vexillarius* separated from present species in genus *Semeiophorus*; however, despite the evident differences in morphology, the two species show notable similarities in vocalizations, breeding strategy, and some roosting and feeding habits, as well as a number of morphological affinities, and so are probably best considered congeneric. Monotypic.

Distribution. Gambia and W Liberia through C Cameroon and N Zaire to SW Sudan, N Uganda and possibly NW Kenya; present in dry season in coastal strip from E Liberia to W Cameroon, and in SE Uganda (Dec-Mar), but breeding not confirmed in these areas. Winters in Sahel zone N of breeding range.

Descriptive notes. 21-22 cm (excluding male's "standards", which reach 45-53.5 cm in length); male 32-65 g, female 32-65 g. Sexually dimorphic, breeding males unmistakable, with strikingly spectacular "standards" on wings. Variable in coloration, male often blacker with whiter speckling, female often buffier or sandier. Upperparts brown speckled greyish-white, crown also speckled buff or tawny, and boldly spotted blackish-brown; broad tawny or tawny-buff nuchal collar; wing-coverts brown, speckled greyish-white and pale tawny and heavily spotted buff; scapulars blackish-brown, broadly edged buff;

supercilium buff, but rather short; throat patch buff barred brown; underparts brown, speckled greyish-white, speckled and spotted buff, becoming buff barred brown on belly and flanks. Both sexes lack white markings on wings and tail. Breeding male has extremely elongated second innermost primaries, which are webbed at tips only, forming "standards" or flags. Iris dark brown, bill blackish, legs and feet dark brown. Smaller than *M. vexillarius*; female slightly smaller and paler with paler nuchal collar and shorter supercilium, lacks white throat patch and has less strongly barred underparts. Immature similar to adult female. **VOICE.** Song of male is a rapid series of soft, high-pitched "ts" notes; also slower, harsher "s-ch" notes. Sings from ground or perches or in display flights. Calls include soft "ch" or "tsui" and low "cuk" notes.

Habitat. Typically occurs in lightly wooded savanna, or savanna with bush or thorn scrub. Also farmland in thickly wooded savanna, open grassy terrain, stony hillsides with scattered trees and vegetation, coastal plains and sandy wastelands; less commonly, pastures, thorn thickets, clearings (often near villages), grassy inselbergs within forest, lawns and paved areas. Recorded from sea-level to 1400 m.

Food and Feeding. Diet includes beetles, moths, grasshoppers, cicadas, earwigs, bugs, leafhoppers, flies, winged ants, winged termites and mosquitoes. Foraging methods poorly described. Forages by hawking for prey over open country and along roadsides and tracks. Also feeds at insect swarms and on insects disturbed by fires.

Breeding. Breeds Mar-Jul in Senegal and Gambia, Nov-Jul in Mali, Feb-May in Liberia and possibly also Togo, Jan-May in Ghana, Jan-Jun in Nigeria. Sept and Feb-Apr in N Uganda, and late Jan to early Apr in N Zaire; periods may be longer than stated, and possibly influenced by rains; S populations breed earlier than N. Polygamous; solitary or semi-colonial; possibly not territorial. Nest-site near vegetation, in grass tussock or clump of small trees, or in open; no nest, eggs laid directly on ground, typically on bare, sandy soil. Males and females gather at display arenas in open spaces. Clutch 1-2 eggs, elliptical, slightly glossy, pinkish-buff, salmon-pink or reddish-chestnut, smeared and spotted brown and grey, laid on successive days; incubation begins with first egg and is mainly by female; chick semi-precocial, covered in buffish down, mottled black on upperparts; female threatened at nest-site may perform injury-feigning distraction display; incubation and fledging periods not documented.

Movements. An intra-African migrant, movements protracted and possibly influenced by rains, not fully understood. Leaves breeding grounds in southern savannas of W & C Africa from mid-Apr to about Aug and moves N to spend wet season in savannas of Sahel and Sudan. E populations move E or NE from Apr. Occurs possibly Aug-Dec in S Mauritania, N Senegal, C Mali, S Niger, N Nigeria and C Chad (N to Ennedi Mts). Also recorded in C & SE Sudan (perhaps mid-Apr to Sept) and W Ethiopia (up to Jan), Uganda and W Kenya. Return movements poorly known. Probable vagrants recorded in W Kenya and N Somalia.

Status and Conservation. Not globally threatened. Widespread and frequent to abundant throughout much of breeding range. Fairly common to abundant from Senegal, Gambia and Sierra Leone E to S Sudan, NW Uganda and NE Zaire; widely distributed in Senegal; locally common in Gambia; not uncommon in Ghana; seasonally common in savanna zone in Togo. Outside breeding season, locally numerous in S Mauritania (late Sept to Oct) and S Niger, uncommon to locally frequent in W & S Ethiopia; rare seasonal visitor to W Kenya; seasonally common intra-African migrant in Nigeria. No data available from other regions. Occurs in a number of protected areas throughout range, e.g. Niokola Koba National Park (Senegal), Gola Forest Reserves (Sierra Leone), W National Park (Niger), Bamingui-Bangoran and Manovo-Gounda-Saint-Floris National Parks (Central African Republic), Kabalega Falls National Park (Uganda) and Awash National Park (Ethiopia).

Bibliography. 83. Pennant-winged Nightjar

Macrodipteryx vexillarius

French: Engoulevent porte-étendard

German: Flaggennachtschwalbe

Spanish: Chotacabras Cuelgacintas

Taxonomy. *Semeiophorus* (*Macrodipteryx*?) *vexillarius* Gould, 1838, Sierra Leone.

Formerly isolated in monotypic genus *Semeiophorus*; however, despite the evident differences in morphology, the two species show notable similarities in vocalizations, breeding strategy, and some roosting and feeding habits, as well as a number of morphological affinities, and so are probably best considered congeneric. Specific name has at times been incorrectly given as *vexillaria*, but *vexillarius* originally described as masculine noun in apposition to masculine genus name. Validity of type locality is questionable, although vagrants have been recorded in several parts of W Africa. Monotypic.

Distribution. C, NE & E Angola, S Zaire and SW Tanzania S to NE Botswana, NE Namibia (Caprivi Strip) and extreme NE South Africa. Winters from SE Nigeria to Uganda.

Descriptive notes. 24-28 cm (excluding male's "pennants", which reach 48-78 cm in length); male 59-79 g, female 65-88 g. Sexually dimorphic, breeding males unmistakable, with strikingly spectacular "pennants" on wings. Upperparts brown, speckled and barred greyish-brown, greyish-white and buff, crown also boldly spotted blackish-brown; broad tawny nuchal collar; wing-coverts brown, speckled buff and greyish-white, speckled and spotted tawny; scapulars generally blackish-brown on inner webs, buff on outer webs; supercilium buff and rather long; throat patch white; underparts brown, tinged and spotted

tawny or tawny-buff, becoming white (male) or buff (female), barred brown, on belly and flanks. Male has blackish wings, narrow white tips to four outermost primaries, white trailing edge to inner wing, and broad white band across eight outer primaries; breeding male has second innermost primaries extremely elongated and generally whitish, forming "pennants"; female has brown wings, broadly barred tawny, and both sexes lack white markings on tail. Iris dark brown, bill blackish-brown, legs and feet pinkish-brown or greyish-brown. Larger than *M. longipennis* is smaller, with female slightly darker with darker nuchal collar, and longer supercilium, buff throat patch and less strongly barred underparts. Immature similar to adult female but paler. **VOICE.** Song of male is a series of rapid, high-pitched "tset" notes given in display flights or from perches. Flight calls are querulous "wheeo" or "chup" notes. Female may utter soft "schurr" calls prior to copulation.

Habitat. Mainly mature miombo or mopane woodland, also other woodland (including burnt or cleared), wooded grassland, open grassland within woodland, bush country, wooded suburban areas, cultivation, disused agricultural areas and gardens, river valleys, burnt open dambos and burnt vleis; also stony hillsides, sandy terrain and teak forest. Tends to avoid acacia bush and thornveld. On passage also in forest clearings and openings, and on wintering grounds also in eucalyptus plantations. Recorded from sea-level to 2800 m.

Food and Feeding. Diet includes moths, beetles, winged termites and ants, crickets, grasshoppers, mantids, cockroaches, earwigs, shield bugs, leafhoppers and cicadas. Forages by hawking for prey in flight, often hunting high above ground. Also makes flycatching sallies from ground. Occasionally forages by day. During non-breeding season, flocks of up to 30 may feed together. Drinks in flight.

Breeding. Breeds Aug-Oct in Angola, late Aug to Nov in Zambia, Aug-Mar in S Tanzania, Oct-Dec in Malawi, Mozambique and Zimbabwe, and Sept-Nov (possibly Dec) in South Africa. Single-brooded. Polygamous; possibly territorial at courtship display arena, but not at nesting site; in some regions semi-colonial, with nests 6.3-19.5 m apart. Nest-site in open or shaded by trees, quite often on burnt ground; no nest, eggs laid on bare ground or leaf litter. Males perform courtship display flights. Clutch 1-2 eggs, elliptical, rounded or almost biconical, glossy, pale to deep salmon-pink, marbled, blotched and spotted dark pink, reddish-brown, violet and grey, laid 1-2 days apart; incubation usually by female, begins with first egg, period 15-18 days; downy chick not described; fledging period not documented.

Movements. An intra-African, transequatorial migrant, although movements rather protracted and not fully understood. After breeding, large flocks may gather prior to migration; often migrates in single-sex flocks, though also in pairs. Leaves breeding grounds Feb-Apr and moves N through S Cameroon, Gabon, Congo, C Zaire, Burundi, Tanzania and SW Kenya. Wintering range (Feb-Oct) apparently SE Nigeria, N & C Cameroon, SW Chad (also Nov record), Central African Republic (possibly except NE), N & NE Zaire, S Sudan and Uganda. Return movements S occur Jul-Oct. Movements occasionally irruptive at times. During N movements and non-breeding season, possible vagrants recorded in Gambia, Guinea Bissau, S Ghana, Togo, SW and NE Nigeria, SW Niger, SE Chad, W Sudan (possibly regular in Darfur), E Sudan and S Somalia. During S movements and breeding season, possible vagrants recorded in N Namibia, W Botswana and South Africa.

Status and Conservation. Not globally threatened. Common to locally abundant throughout much of breeding range, from C Angola E through S Zaire to SW Tanzania, S to NE South Africa. Extremely common to locally abundant in Zambia; very common in Malawi; locally common throughout Zimbabwe; sparsely distributed in Botswana; listed as indeterminate in South African Red Data Book. An uncommon transequatorial migrant in Nigeria; uncommon in Gabon; a common passage migrant across N Congo and much of Zaire; uncommon in Burundi; locally and seasonally scarce to casual in W Kenya; probably not common in Tanzania. Occurs in several protected areas, e.g. Bamingui-Bangoran and Manovo-Gounda-Saint-Floris National Parks (Central African Republic), Kabalega Falls National Park (Uganda), Akagera National Park (Rwanda), Ruvuvu National Park (Burundi) and Kafue National Park (Zambia).

Genus *HYDROPSALIS* Wagler, 1832

84. Ladder-tailed Nightjar

Hydropsalis climacocerca

French: Engoulevent trifle

Spanish: Chotacabras de Escalera

German: Staffelschwanz-Nachtschwalbe

Taxonomy. *Caprimulgus climacocercus* Tschudi, 1844, Peru. Validity of races *intercedens*, *pallidior* and *canescens* questionable, as all three occur along a 120-km stretch of the lower Amazon between Obidos and Santarém, and all remain virtually unknown. Five subspecies currently recognized.

Subspecies and Distribution.

H. c. schomburgki P. L. Slater, 1866 - E Venezuela and the Guianas.

H. c. climacocerca (Tschudi, 1844) - SE & E Colombia to S Venezuela, and S to N & E Bolivia.

H. c. intercedens Todd, 1937 - NC Brazil: known only from type locality at Obidos in W Pará.

H. c. pallidior Todd, 1937 - NC Brazil: known only from type locality at Santarém in W Pará.

H. c. canescens Griscom & Greenway, 1937 - NC Brazil: known only from lower Tapajós in W Pará.

Descriptive notes. 24-26 cm; male 42-46 g, female 45-52 g. Sexually dimorphic. Upperparts greyish-brown or brownish, streaked blackish-brown; buffish nuchal collar; wing-coverts brown or greyish-brown, boldly spotted buffish; scapulars blackish-brown, broadly edged buff on outer webs; white submoustachial stripe and white (male) or buffish (female) throat patch; underparts greyish-brown or brown, barred and spotted buff, becoming buff barred brown on belly and flanks. Male has broad white band across four outermost primaries and much white in tail; female has narrower white wing bands and

rarely shows white in tail. Iris dark brown, bill blackish, legs and feet brownish. Slightly smaller and paler than *H. torquata*, with duller nuchal collar and prominent white wing bands; male has much shorter tail. Immature similar to adult female. Racial variation often slight, involving size and overall coloration. Voice. Song, or perhaps call, is a repetitive, high-pitched "chip". Calls include soft, musical "chewit" or "cheeit" notes.

Habitat. Typically, rainforest, open woodland, secondary growth, riverine forest and grassland, on riverbanks, sandbars, and stones and rocks in rivers; also in areas with thickets. Lowland species, recorded from sea-level to 500 m.

Food and Feeding. Diet poorly studied, but probably feeds on insects. Foraging methods poorly documented. Forages by making short sallies from low perches or sandbars, hawking after prey along river edges.

Breeding. Poorly known. Breeds possibly late Jul to Aug (probably longer) in Colombia and Dec-Feb in Brazil (NW Amazonas); no data from other regions. Nest-site on mudflats, sand, or among driftwood, usually shaded by vegetation; no nest, eggs laid on sand or bare soil. Clutch 2 eggs, elliptical, olive-drab, speckled, spotted and scrawled grey and brown; incubation and fledging periods not known; downy chick not described.

Movements. None documented. Sedentary.

Status and Conservation. Not globally threatened. In Colombia, common along large rivers where there are sandbars and river islands. In Surinam, common along rivers where there are plenty of rocks and stones. No data available from other countries. Occurs in Amacayacu National Park (Colombia) and Tambopata Reserve (Peru).

Bibliography. Allen (1995), Blake (1950b), Butler (1979), Chebez (1994), Davis *et al.* (1994), Donahue (1994), Friedmann (1948), Griscom & Greenway (1937), Haverschmidt & Mees (1994), Hilty & Brown (1986), Hoy

(1987), Meyer de Schauensee & Phelps (1978), Parker *et al.* (1982), Remsen & Traylor (1989), Schubart *et al.* (1965), Sick (1993, 1997), Snyder (1966), Stotz *et al.* (1996), Todd (1937a), Tostain *et al.* (1992).

85. Scissor-tailed Nightjar

Hydropsalis torquata

French: Engoulevent à queue en ciseaux

Spanish: Chotacabras Tijereta

German: Scherenschwanz-Nachtschwalbe

Taxonomy. *Caprimulgus torquatus* J. F. Gmelin, 1789, Brazil.

Species name has normally been given as *brasiliensis*, but this name is based on a drawing and a written description, and is not clearly identifiable as present species, indeed some points would appear to preclude this: *torquata*, proposed by same author on the following page of the same publication, was consistently used in Brazilian literature until 1966, and should be reinstated. Two subspecies recognized.

Subspecies and Distribution.

H. t. torquata (J. F. Gmelin, 1789) - S Surinam, EC Peru and Brazil.

H. t. furcifera (Vieillot, 1817) - N & E Bolivia, S Brazil, Paraguay, N & C Argentina and Uruguay.

Descriptive notes. 25-30 cm (excluding outer tail feathers of male, which reach 27-36 cm in length); male 47-52 g, female 48-75 g. Sexually dimorphic. Upperparts brown streaked blackish-brown; broad tawny or buff nuchal collar; wing-coverts brown, heavily spotted buff and greyish-white, with distinct buffish line along scapulars; thin whitish submoustachial stripe; throat pale but no obvious white patch; underparts brown, barred and spotted buff, becoming pale buff or buffish-white barred brown on belly and flanks. Both sexes lack white markings on wings. Male has much elongated whitish outermost tail feathers edged

brown; female has shorter tail that lacks white. Iris dark brown, bill dark brown tipped black, legs and feet brownish. Slightly larger and darker than *H. climacocerca* with more rufous nuchal collar, lacks white wing bands and male has longer, darker tail. *Macropsalis forcipata* is larger, darker and longer-winged, and male has much longer tail. *Uropsalis lyra* is browner and paler; male also has much longer tail. *Uropsalis segmentata* is smaller, darker and more spotted, has no nuchal collar and no obvious scapular pattern, and again male has much longer tail. Immature plumages not yet described. Race *furcifera* is larger, even longer-tailed and often paler, with paler nuchal collar. Voice. Song of male is a repetitive series of short "tsip" notes given from perches and occasionally in flight. Flight call is a high-pitched "tsig".

Habitat. Typically, forest, woodland and *cerrado*; also espinilho grassland with scattered vegetation, *campo sujo*, eucalyptus and acacia groves, urban parks and suburban parkland. Recorded at c. 500 m.

Food and Feeding. Diet includes beetles, moths, flies, mayflies, bugs, ants and Orthoptera. Foraging methods poorly studied; forages by making flycatching sallies from perches.

Breeding. Poorly known. Breeds Nov-Jan in SE Brazil; no data from other regions. Territorial. Nest-site in vegetation on rocky hillside, or among small acacias; no nest, eggs laid on bare soil or granite. Male performs courtship displays on ground, stretching and closing wings, producing wing-clapping sounds during which often rises slightly into air; also short flights during displays, wing-clapping when realighting. Clutch 2 eggs, elliptical, creamy-white, pinkish-buff or light brown, densely scrawled grey and brown; incubation and fledging periods not documented; downy chick not described.

Movements. Poorly known. Some populations may be partially migratory, e.g. race *furcifera* disappears from many areas of Rio Grande Do Sul, S Brazil, during non-breeding season.

Status and Conservation. Not globally threatened. Probably not common in Surinam and possibly restricted to S, where at N limits of range; generally rare in Paraguay, though possibly common locally in N; in Brazil, uncommon in Atlantic forest region, rare and seasonal May-Oct in Mato Grosso, common in Rio Grande Do Sul; locally common in parts of N Argentina; no data available from other regions. Disjunct population in C Peru appears to be an isolated one. Occurs in several protected areas, e.g. Noel Kempff Mercado National Park (Bolivia), Serra da Canastra and Das Emas National Parks (Brazil), Costanera Sur Ecological Reserve (Argentina).

Bibliography. dos Anjos *et al.* (1997), Barnes *et al.* (1993), Belton (1984), Brooks *et al.* (1993), Canevari *et al.* (1991), Contreras *et al.* (1990), Davis (1993), Dubs (1992), Haverschmidt & Mees (1994), Hayes (1995), Klimantis & Moschione (1987), Madroño *et al.* (1997), Miserendino (1998), Narosky, S. *et al.* (1990), Narosky, T. & Yzurieta (1993), Navas & Bo (1991), Nellar (1993), Pacheco & Whitney (1998), Parker & Goerck (1997), Parker *et al.* (1982), de la Peña (1994), Remsen & Traylor (1989), Rodríguez (1984), do Rosário (1996), Saibene *et al.* (1996), Short (1975), Sick (1993, 1997), Stotz *et al.* (1996), Teixeira (1992), de Urioste (1994), Wetmore (1926), Willis (1992).

Genus *UROPSALIS* W. deW. Miller, 1915

86. Swallow-tailed Nightjar

Uropsalis segmentata

French: Engoulevent à queue d'aronde **Spanish:** Chotacabras Golondrina
German: Schwalbenschwanz-Nachtschwalbe

Taxonomy. *Hydrosalis segmentatus* Cassin, 1849, Bogotá.
Two subspecies recognized.

Subspecies and Distribution.

U. s. segmentata (Cassin, 1849) - Colombia (W slope of Andes and E Andes) and N Ecuador.
U. s. kalinowskii (Berlepsch & Stolzmann, 1894) - C Peru (slopes of E Andes) and W & C Bolivia.

Descriptive notes. 20-22 cm (excluding outer tail feathers of male, which reach 40-7-54 cm in length); 1 male 45 g, 1 female 50 g. Sexually dimorphic. Upperparts dark brown, heavily spotted tawny, no nuchal collar; wing-coverts dark brown, spotted and barred tawny and buff, no scapular pattern; lacks white submoustachial stripe, tawny throat patch faint to absent; underparts dark brown, spotted tawny and buff, becoming tawny-buff barred brown on belly and flanks. Both sexes lack white markings on wings. Male has greatly elongated outermost tail feathers edged white, female having shorter, darker tail. Iris brown, bill blackish, legs and feet brownish.

isish. Smaller, darker and plainer than *U. lyra*, without tawny nuchal collar and throat band much reduced or absent; male has shorter tail. Smaller and plainer than *Macropsalis forcipata*, lacking buff along scapulars and tawny nuchal collar; male shows much less white in tail. Smaller, darker and plainer than *Hydrosalis torquata*, lacking buff along scapulars and tawny or buff nuchal collar; male has longer tail. Immature similar to adult. Race *kalinowskii* is similar but male has shorter tail. **VOICE.** Song of male is a whistled "purr-r-sweeee" that rises, then descends in pitch; sings from ground. Calls include low churrs.

Habitat. Typically, forest clearings, glades and openings and along forest edges, often preferring areas with bamboo, coarse grass or shrubby vegetation; recorded in humid, cloudforest and elfin forest. Also found in *páramo*, clearings along tree-line, and on open or sparsely vegetated slopes. Generally recorded at 2300-3600 m, but recent record from 1950 m on Mt Pichincha, N Ecuador.

Food and Feeding. Diet poorly studied, but probably feeds on insects. Forages by making short sallies from ground or perches. When foraging, flies low over ground, and hunts over open, grassy slopes and along forest edges.

Breeding. Very poorly known. Breeds Aug-Sept and Jan-Feb in Colombia; no data from other regions. Males perform courtship displays in which they circle and chase several females. Eggs elliptical.

Movements. None documented. Possibly sedentary.

Status and Conservation. Not globally threatened. In Colombia, considered locally uncommon to fairly common in suitable habitat; locally fairly common in suitable habitat throughout rest of Andean range. Regularly recorded in Puracé National Park, Colombia. Recently recorded from W slope of Andes in Pichincha, Ecuador, where three males were located; this area is heavily clear-cut, with frequent landslides, possibly making it more suitable for present species. No data available from other regions.

Bibliography. Butler (1979), Fjeldså & Krabbe (1990), Hilty & Brown (1986), Mazar, Kirwan & Tobias (1998), Meyer de Schauensee (1982), Olrog (1968), Parker *et al.* (1982), Remsen & Traylor (1989), Roe & Rees (1979), Stotz *et al.* (1996), Vélez & Velázquez (1998), Vuilleumier (1969), Welford (1998).

87. Lyre-tailed Nightjar

Uropsalis lyra

French: Engoulevent lyre **German:** Leierschwanz-Nachtschwalbe **Spanish:** Chotacabras Lira

Taxonomy. *Hydrosalis lyra* Bonaparte, 1850, Bogotá.
Three subspecies recognized.

Subspecies and Distribution.

U. l. lyra (Bonaparte, 1850) - W Venezuela, W Colombia and C Ecuador.
U. l. peruana (Berlepsch & Stolzmann, 1906) - C & E Peru and W & C Bolivia.
U. l. argentina Olrog, 1975 - N Argentina and possibly S Bolivia.

Descriptive notes. 25-28 cm (excluding outer tail feathers of male, which reach 63-5-80 cm in length); 1 male 68-5 g, female 74-79 g. Sexually dimorphic. Upperparts brown, spotted greyish-white, buff, tawny and cinnamon; broad tawny or tawny-buff nuchal collar; wing-coverts brown, boldly spotted tawny and buff, no scapular pattern; tawny or buff band around lower throat; underparts brown, spotted and barred tawny, buff and cinnamon, becoming buff barred brown on flanks and lower belly. Both sexes lack white markings on wings. Male has extremely elongated outermost tail feathers tipped white; female's much shorter tail lacks white. Iris brown, bill blackish, legs and feet brownish. Smaller than *Macropsalis forcipata*, lacking buff along scapulars but with tawny or buff throat band; male has longer, darker tail. Larger, paler and more variegated than *U. segmentata*, with prominent nuchal collar and throat band; male has longer tail. Slightly paler than *Hydrosalis torquata*, and male has darker and much longer tail. Immature plumages not described. Races vary clinally in size; *peruana* is quite reddish in coloration; *argentina* has whiter markings on breast, and male's elongated outer tail feathers are tipped greyish, not white. **VOICE.** Song of male is a series of rising "wécou-tee" notes given from ground or perches. During courtship display flights, utters rapid "weep, weep, weepup"; calls include "weep, weep, weep" or "chip, chip, chip".

Habitat. Typically, humid cloudforest or rainforest, in clearings, openings and glades and along forest edges, and often near cliffs, rocky ravines or cave entrances; also open woodland, where often close to water. In Argentina, can also occur in scrub along edges of alder forest. Recorded at 800-3500 m.

Food and Feeding. Diet poorly studied, but probably feeds on insects. Foraging methods not fully described. Forages by making short sallies from ground or perches, hunting along forest edges and around clearings.

Breeding. Almost entirely undocumented. Breeds Jun-Aug and Dec in Colombia; no data from other regions. Territorial; males display to other males by hovering and flicking the elongated tail feathers to and fro, and perform courtship display flights at communal lek. No other information.

Movements. None documented. Most likely sedentary.

Status and Conservation. Not globally threatened. Local in Colombia, where recorded on Andean slopes, generally between 800-2500 m, from Valle, Antioquia, S to Cauca and Huila, and from Boyacá and Santander S to Huila; rare in Nariño, where only a few records from Pacific slope. In Ecuador, regularly recorded at Mindo, Tena and Chiriboga. In Peru, present at Tingo María. In Argentina, probably locally common in Calilegua National Park, Jujuy, where small breeding population discovered in 1997. Local throughout remainder of Andean range.

Bibliography. Boesman (1998), Butler (1979), Canevari *et al.* (1991), Chebez (1994), Fjeldså & Krabbe (1990), Fjeldså & Mayer (1996), Hilty & Brown (1986), Mazar, Pugnali & della Seta (1998), Meyer de Schauensee & Phelps (1978), Narosky & Yzurieta (1993), Olrog (1975), Parker, Bates & Cox (1992), Parker, Parker & Plenge (1982), de la Peña (1994), Remsen & Ridgely (1980), Remsen & Traylor (1983, 1989), Salaman & Gandy (1994), Stotz *et al.* (1996), Vuilleumier (1969).

Genus *MACROPSALIS* P. L. Sclater, 1866

88. Long-trained Nightjar

Macropsalis forcipata

French: Engoulevent à traine **Spanish:** Chotacabras Coludo
German: Hakenschwanz-Nachtschwalbe

Taxonomy. *Caprimulgus forcipatus* Nitzsch, 1840, Brazil.

Species name has commonly been given as *creagra*, but *forcipata* has priority by ten years; contrary to some claims, *forcipata* has been regularly used in literature during the past 50 years, by Brazilian ornithologists, and so should stand. Monotypic.

Distribution. SE Brazil, in Espírito Santo, Minas Gerais (possibly), Rio de Janeiro, São Paulo, Paraná, Santa Catarina (possibly) and Rio Grande do Sul; also NE Argentina (Misiones).

Descriptive notes. 28-31 cm (excluding outer tail feathers of male, which reach 48-68 cm in length). Sexually dimorphic. Upperparts brown, spotted and barred greyish-brown, tawny, buff and cinnamon; broad tawny or tawny-buff nuchal collar; lesser coverts brown, barred or spotted tawny, rest of wing-coverts brown, boldly spotted tawny and buff; shows buffish line along scapulars; no white submoustachial stripe, faint throat patch tawny; underparts brown, barred and scalloped tawny and buff, becoming buff barred brown on belly and flanks. Both sexes lack white markings on wings. Male has greatly elongated outermost

tail feathers, broadly edged whitish on inner webs; female has shorter, darker tail. Iris brown, bill blackish, legs and feet brown. Larger, darker and longer-winged than *Hydrosalis torquata*, and male has much longer tail. Larger than *Uropsalis lyra*, with well-marked scapular pattern, but throat band much fainter; male has shorter, paler tail. Larger and more variegated than *Uropsalis segmentata*, with prominent scapular pattern and nuchal collar; male shows much more white in tail. Immature plumages not described. **VOICE.** Call, given by both sexes, is a repetitive, high-pitched "tsip, tsip, tsip, tsip".

Habitat. Occurs mainly in forest and woodland, in second-growth forest, and at forest edge; in more N parts of range, tends to prefer forest in more mountainous regions. Recorded from sea-level up to 1800 m.

Food and Feeding. Diet poorly studied, but probably feeds on insects. Foraging methods poorly documented. Forages by flying close to trees and taking insects from leaves; hawks for prey in flight, and feeds on insects attracted to artificial lights; also recorded feeding from ground, beside a path, making short sallies and returning to same spot.

Breeding. Breeds possibly Nov-Jan in S Brazil; probable courtship recorded in late Sept, in NE Argentina; no data from other regions. Nest-site often shaded by vegetation, e.g. lichens and bushes; no nest, eggs laid on leaf litter on ground. Male performs courtship display on areas of bare ground, puffs out throat and raises tail at right angle to form conspicuous white V, can also hover around perched female with tail spread downwards; display areas used for up to 2 months. Eggs elliptical, pinkish-blue, speckled chestnut and buff; incubation mainly by female during day, period not known; female threatened at nest-site may perform distraction display; chick covered in greyish down, streaked buffish-chestnut and black; fledging period not known.

Movements. None documented. Possibly sedentary.

Status and Conservation. Not globally threatened. Currently considered Near-threatened. Endemic to rainforests of SE Brazil and NE Argentina. Possibly rare to locally common in SE Brazil, e.g. common in Paraná and São Paulo, rare in Rio Grande do Sul, rare in Itatiaia National Park; also present in Serra do Cipó and Serra da Canastra National Parks. Rare or perhaps very local in NE Argentina (Misiones); no data available from other regions. Throughout its limited range, habitat loss due to destruction of rainforests poses a serious threat.

Genus *ELEOTHREPTUS* G. R. Gray, 1840

89. Sickle-winged Nightjar

Eleothreptus anomalus

French: Engoulevent à faucilles

Spanish: Chotacabras Pantanero

German: Sichelschwinger-Nachtschwalbe

Taxonomy. *Amblypterus anomalus* Gould, 1838, São Paulo, Brazil.

Closest relative may be *Caprimulgus candicans*, which may even be congeneric (see page 305). Monotypic.

Distribution. S Brazil (Distrito Federal and Minas Gerais, patchily S to Rio Grande do Sul), C & S Paraguay (Concepción to Misiones) and N & NE Argentina (Misiones to Buenos Aires).

Descriptive notes. 18–20 cm; 1 male 43.5 g. Sexually dimorphic, with differences most readily apparent in flight. Upperparts pale greyish-brown, lightly spotted dark brown, boldly spotted blackish-brown on head; occasionally shows indistinct buffish nuchal collar; wing-coverts generally pale greyish-brown, barred blackish-brown and streaked pale buff, showing distinct cinnamon patch, distally edged whitish, on primary coverts; scapulars pale greyish-brown with irregularly shaped blackish-brown centres; pale buffish-white stripe above eye; no noticeable submoustachial stripe or white on throat; underparts darkish brown tinged cinnamon, barred brown, becoming pale buff indistinctly barred brown on lower belly and flanks. Male has distinctive wing shape with curved outer primaries tipped white and all but central tail feathers broadly tipped white or buffish-white; female browner. Iris dark brown, bill brownish or blackish, legs and feet brownish. Juvenile similar to adult female, although upperparts tinged cinnamon, especially on wing-coverts, and speckled or spotted white. **VOICE.** Calls include soft, repetitive “chip”, “tchup” or “tchut”, from ground or in flight. Flight call of female ■ harsh, nasal “gzee, gzee”.

Habitat. Edges of gallery forest, along streams or rivers through gallery forest, in monte (chaco-type woodland) or transitional woodland. In NE Argentina, recorded in grassland with areas of

chañar monte that are subject to periodic flooding. Also savanna and grassland, marshland, swamps, *campo*, scrubby edges of lagoons, and edges of streams, pools and flooded palm groves.

Food and Feeding. Diet poorly studied, but includes beetles, moths and ants. Foraging methods poorly documented. Forages in flight by fluttering and gliding low over vegetation in open country and over grassy tracks; when hunting, often rises suddenly to chase after prey.

Breeding. Poorly known. Breeds possibly Aug–Jan in SE Brazil (Aug in Paraná, Nov to early Jan in São Paulo) and Sept–Dec in NE Argentina.

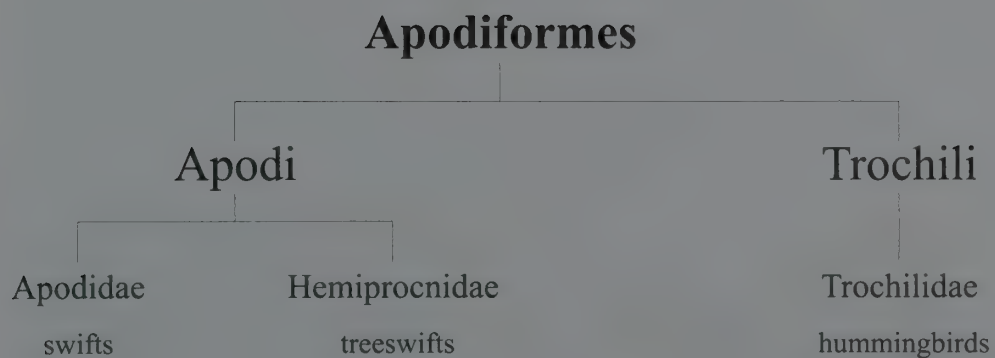

tina; no data from other regions. Territorial. Male performs courtship displays in flight, with wing-flapping sounds. Eggs elliptical or ovate, pinkish-buff or pale buffish, spotted and scrawled brown and grey; incubation and fledging periods not known; downy chick not described.

Movements. Very poorly known. May be migratory in parts of range, S populations moving N during non-breeding season, Apr–Aug.

Status and Conservation. Not globally threatened. Currently considered Near-threatened. Very scarce and little known throughout range, though possibly under-recorded in many regions. In Brazil, officially protected by legislation; several protected areas, e.g. Brasília National Park, Serra da Canastra National Park and Cambuí Biological Reserve, appear to hold populations. Probably rare in Paraguay, where listed as threatened; however, recent fieldwork suggests it may be a regular inhabitant of areas of marshy grassland in E Paraguay, with apparent scarcity possibly attributable to patchy distribution and inconspicuous nature of the species; nevertheless, few definite records. In Argentina, recorded in National Parks such as El Palmar, Diamante, Pilcomayo, Mburucuyá and Iguazú, but probably a summer migrant only, moving N during austral winters. Major threat throughout range appears to be loss of habitat due to drainage, fires, cultivation, ranching, and overgrazing and trampling by livestock; also in Curitiba region of Paraná, Brazil, sand extraction and building of roads and dams, and in NE Argentina possible creation of large eucalyptus and pine plantations by forestry industry. Increasing road traffic occasionally claims some victims; collision with overhead power cables also possibly responsible for some deaths.

Order APODIFORMES

Class AVES
Order APODIFORMES
Suborder APODI
Family APODIDAE (SWIFTS)

- Small to medium-sized aerial birds with long, narrow wings and short, thin legs, but strong toes with sharp claws; plumage generally rather drab.
- 9-25 cm.

- Cosmopolitan.
- Wide variety of habitats, usually not far from water.
- 19 genera, 92 species, 276 taxa.
- 6 species threatened; none extinct since 1600.

Systematics

The mainstream taxonomic view prevailing before the advent of "accessible" molecular biology was that the swifts were most closely allied to the hummingbirds (Trochilidae), with a few researchers holding out for an alliance with the nightjars and their relatives (Caprimulgiformes). Thus, the families Apodidae ("typical" swifts) and Hemiprocnidae (treeswifts) have normally been grouped along with Trochilidae in a single order, Apodiformes. In their ground-breaking work based on DNA-DNA hybridization analysis, C. G. Sibley and J. E. Ahlquist consider that, in the broadest sense, the owls (Strigiformes), the caprimulgiforms, the swifts and the hummingbirds form a monophyletic assemblage, and the traditional view that hummingbirds and swifts are close allies is further vindicated. In the arrangement proposed by these authors, the order Apodiformes, containing the families Apodidae and Hemiprocnidae, is placed with the Trochiliformes within the superorder Apodimorphae.

Divisions within the Apodidae are less certain. Two subfamilies are generally recognized. The 13 species of Cypseloidinae, comprising the genera *Cypseloides* and *Streptoprocne*, are the most ancient and least contentious: these forms do not use saliva in nest-building, and they have two carotid arteries and a primitive palate. The larger subfamily, the Apodinae, consists of three tribes. These are the Collocaliini, with the genera *Hydrochous*, *Collocalia*, *Aerodramus* and *Schoutedenapus*; the Chaeturini, containing the seven genera *Mearnsia*, *Zoonavena*, *Telecanthura*, *Rhaphidura*, *Neafrapus*, *Hirundapus* and *Chaetura*; and the Apodini, comprising *Aeronautes*, *Tachornis*, *Panyptila*, *Cypsiurus*, *Tachymarptis* and *Apus*. All members of these three tribes have a well-developed transpalatine process and one carotid artery, and all except the needletails (*Hirundapus*) use saliva in nest-building. The Chaeturini are sometimes given subfamily status as Chaeturinae. While *Schoutedenapus* is currently placed within the Collocaliini, our limited knowledge of this genus and its enigmatic members mean that its position remains far from certain.

Subdivision of the
Apodidae

[Figure: Ian Lewington]

The earliest swift-like bird, *Primapus lacki*, was described from early Eocene sediments in England and named in honour of the famous swift researcher David Lack. It was placed in the family Aegialornithidae, along with five other species described from late Eocene to Oligocene deposits in France. *Primapus* apparently died out at the end of the Eocene, although another swift genus, *Cypselavus*, described from the same French strata and originating in the Eocene, survived into the Oligocene. The Lower Eocene Green River Formation of Wyoming, USA, has yielded a small *Chaetura*-like swift, while "true swifts" of a modern genus occur in French deposits of the late Eocene (*Cypseloides mourerchauvirei*) and early Miocene (*Cypseloides ignotus*).

A. Karkhu considers that two major lineages of swift evolution can be identified and that current systematics should reflect this. First, the Paleogene, or early Eocene, taxa *Aegialornis*, *Primapus* and *Cypselavus* can be united with the genus *Hemiprocne* (modern treeswifts) in the family Hemiprocniidae. Second, the paleogenera *Procypseloides* and *Scaniacypselus*, along with the Paleogene apodiform family Jungornithidae, the Apodidae and the Trochilidae are united by the common possession of a humerus structure radically different from that of the Hemiprocniidae so defined. The first group forms Karkhu's suborder Hemiprocni, while the second, with the hummingbirds excluded, represents his suborder Apodi.

R. K. Brooke reviewed recent apodid evolution, speculating that the Cypseloidinae are the most primitive group, now restricted to a relict New World distribution, while the Apodini are the most advanced, with the Collocaliini and Chaeturini as intermediates. The rationale behind this treatment is based upon anatomical and morphological differences and the apparent development of elaborate and specialized nests and nest-sites.

Brooke's consideration of the evolution of the Chaeturini is an elegant argument based upon the degree of polytypism and patterns of distribution within New and Old World representatives of the tribe. Old World representatives are highly dissimilar, with generally fewer subspecies and disjunct distributions, as compared to their New World allies, which are very similar to one another, with a plethora of subspecies and more extensive, continuous ranges. Brooke argues that this picture suggests adaptive radiation in the New World from an "Old World stock".

The view that taxonomic conundrums within this family could be largely resolved by analysis of nest morphology has been dealt a severe blow with the realization that many species are facultative nest-builders, while a good example of the equivocal role of morphology comes from the Cypseloidinae, where it is apparent that tail spines, which were previously considered to indicate phylogeny, are in fact a function of body size and roosting habits.

The taxonomic uncertainty so prevalent in this family has its maximum expression in the swiftlets, formerly all placed in the

Swifts are well known as being amongst the most aerial of all birds. In common with several other bird families they regularly feed on the wing, but, much more remarkably, it is thought that they sometimes actually copulate in mid-air, although this is certainly very difficult to prove. They are also extraordinary in the habit of aerial roosting; to date this has been convincingly demonstrated for only one species, the Common Swift, which has been seen to collide with aircraft while roosting high in the sky. Popular belief has it that they fly faster than any other birds, but this is probably something of an exaggeration, although there is no doubt that their normal flight is fast. The structure of the wing is clearly visible in this Common Swift. Note the long, narrow primaries and the very short secondaries, an arrangement which facilitates fast flight and efficient gliding.

This Pacific Swift shows several morphological features of interest in the Apodidae, such as the sharp claws. Of particular note is the large eye, which is typically sunk back into the face, with a patch of dark, bristle-like feathering in front of it. These feathers can be moved by muscles in order to adapt to the angle of incidence of the sun's rays, and they almost certainly help to reduce glare, which could otherwise be a major problem for birds that spend much of their lives flying around in direct sunlight.

genus *Collocalia*, and which J. L. Peters described as one of the most difficult of all groups of birds. As recently as 1970, Brooke split *Collocalia* into three groups: *Hydrochous*, containing the large waterfall-dwelling Waterfall Swift (*Hydrochous gigas*); *Collocalia*, containing glossy, non-echolocating species; and *Aerodramus*, containing non-glossy species, including echolocating taxa. This proposal is supported by recent studies of phylogeny within the Collocaliini, and specifically of the correlation between phylogeny and behaviour. These studies concluded that comparisons of cytochrome *b* sequences strongly suggest that the Collocaliini are not monophyletic, although "evidence in support of a Collocaliini clade is provided by ectoparasitic lice...*Collocalia*, *Aerodramus*, and *Hydrochous* are all parasitized by the louse subgenus *Collodemyus* (genus: *Dennyus*), which is found in no other host". The researchers also noted that there was no evidence of consistency between nest-building behaviour and their molecular phylogeny, whereas echolocation showed better agreement. A holistic approach to taxonomy in this group, and the family as a whole, using molecular data, morphology and biology, will no doubt give a clearer picture of many of these issues.

Very recently, in 1998, J. Holmgren presented a parsimonious phylogenetic tree for the Apodiformes, "consistent with a hypothetical historical narrative and zoogeographical facts". This placed *Schoutedenapus* in the tribe Apodini and included the treeswifts as a tribe Hemiprocnini within the Apodinae. Holmgren suggested that, at a higher taxonomic level, behavioural characters might reveal an evolutionary conservatism in the swifts not unlike that found in the swallows and martins (*Hirundinidae*). Unsurprisingly, however, he concluded that all taxa should be fully analysed, using all available techniques, before any real consensus could be established.

Morphological Aspects

As anyone examining a swift would agree, both the genus name *Apus*, from the Greek *a-pous*, meaning "without foot", and the former name for the order, *Machrochires*, "with large hands" (referring to the outer wing), are well chosen.

The swift wing, when compared with those of other bird families, is instantly recognizable by its nine or ten long primaries and

its compressed block of eight to eleven very short secondaries. Remarkably, the longest primary can measure up to three times the length of the shortest secondary, compared with only twice the length in the evolutionarily convergent *Hirundinidae*. This is a function of the very long carpometacarpus, which considerably exceeds the length of the radius and ulna. Both the primaries and the secondaries produce a powerful forward force, with the primaries providing an additional downward force, while lift is produced mainly in the secondaries. This configuration gives members of this family great speed. The Chimney Swift (*Chaetura pelagica*) was among the fastest of 12 species monitored for flight speed using Doppler radar, while swiftlets entering cave breeding sites have been recorded flying at up to 111 km per hour. Various speeds much greater than this have been claimed for a number of larger species: notably, White-throated Needletails (*Hirundapus caudacutus*) have allegedly been recorded flying at 170 km per hour. The uniquely long and narrow wing shape is advantageous during flapping flight, but actually favours gliding, and this may explain the low flight-metabolism figures recorded for swifts. In addition, the tendency to glide reduces the need for powerful breast muscles, as shown by the figures for breast/body weight of 15.5% and 19.5% for Alpine Swifts (*Tachymarpis melba*) and Pallid Swifts (*Apus pallidus*) respectively, as compared with 26.5% for the pigeons (*Columbidae*), a group of typical flapping birds.

Swifts normally have ten rectrices, although there is a remarkable example of polyrectricity, a Common Swift (*Apus apus*) with 12 rectrices, but beyond this the general form of the tail is highly variable. A tail fork is a prominent feature of many Apodini, while the tails of swiftlets have only shallow furcation. Several species have an enhanced tail fork resulting from deep emargination and extension of the outer rectrices; this is most apparent in the genera *Panyptila*, *Tachornis* and *Cypsiurus*. In the tribe Chaeturini, and to a lesser extent in the Cypseloidinae, the rectrix rachides extend beyond the feather tips, causing the distinctive "spines" or "needles" after which many of these species are named. They are analogous with the stiffened tails of woodpeckers (*Picidae*) and treecreepers (*Certhiidae*), serving to support the birds when they alight on vertical surfaces. Some species within the Chaeturini have a remarkably short tail, notably the Neotropical Short-tailed Swift (*Chaetura brachyura*) and the Afrotropical Böhm's Spinetail (*Neafrapus boehmi*). This short-

Members of the Chaeturini, like these White-throated Needletails, are characterized by the unusual structure of the tail feathers, with the rachides bare at the tips and stiffened along their whole length, both of which features combine to help the birds cling to vertical surfaces. They are amongst the glossiest of all swifts, and it is interesting to speculate on possible aerodynamic functions of both the glossy plumage and the "spiny" tails.

fall in the tail is perhaps countered by a distinctive broadening of the secondaries, which probably enhances manoeuvrability.

The tiny feet of swifts belie their effectiveness. Anyone who has handled these birds will be aware of the strength of their feet and the sharpness of their curved claws. These features, together with calluses on the tarsi and stiff tail feathers, are essential for gripping onto vertical surfaces, though the feet are generally useless for perching. All but one of the swifts have four toes, the sole exception being the Papuan Swiftlet (*Aerodramus papuensis*), which has three, having lost the hallux, or hind toe. In an important revision of the literature on the arrangement of the toes in swifts, C. T. Collins noted that the Chaeturini and the Cypseloidinae possess a typical anisodactyl foot, with the hallux directed backwards and the second, third and fourth toes directed forwards; the Collocaliini also share this feature. At the same time, he revised views of the much-vaunted pamprodactyly in the Apodinae. This arrangement, with all toes pointing forwards, is commonly exhibited in museum specimens, but living birds adopt it only when the toes fail to gain purchase, as on a smooth, hard surface. In the typical grasping formation, the first and second toes (the hallux and innermost) are spread medially, together or slightly apart, and oppose toes 3 and 4 (the central and outermost), which are spread laterally. This arrangement is also shown by chameleons (*Chamaeleo*) and phalangeroid mammals such as the koala (*Phascolarctos cinereus*), a situation which appears to represent, as Collins states, "a particularly clear but overlooked case of convergence among these three classes of climbing vertebrates".

Evidence from blood-testing shows profound physiological adaptation to a high-altitude way of life. The haemoglobin is sensitized for optimum delivery of oxygen in conditions of low oxygen pressure. Erythrocyte dimensions are generally greater than in other bird families, facilitating exchange of oxygen, and oxygen affinities are significantly higher than those recorded in passerines.

The gape is very large, facilitating the aerial capture of insects, although the bill itself is quite tiny. The eyes of all species of swift are protected by coarse, bristle-like feathers located immediately in front of the eye; the angle of these feathers can be altered by muscles. These "bristles" are black, and this, coupled with the deeply recessed position of the eyes, suggests that they may also play a role in reducing glare directly onto the eye. Swifts are far-sighted and focus both monoptically and bioptically. They

have both central and lateral foveae. One species, the Spot-fronted Swift (*Cypseloides cherriei*), has particularly large eyes which account for an astonishingly high proportion (5.5%) of its body mass. It is also thought that this species, like its congener the White-chinned Swift (*Cypseloides cryptus*), may be able to use very basic echolocation.

Echolocation is highly developed in a number of swiftlet species. Unlike bats (Chiroptera), however, swiftlets do not apparently have the echolocating acuity needed to home in on insect prey. Rather, this facility gives them the advantage of being able to nest in dark cave sites, as well as to feed later into the evening than non-echolocating species, so that they can return to their caves after dark. The work of Lord Medway and J. D. Pye showed that the echolocating group of swiftlets might be diphyletic, with the majority uttering a double orientation click, while the Atiu Swiftlet (*Aerodramus sawtelli*) and the race *lowi* (at least) of the Black-nest Swiftlet (*Aerodramus maximus*) utter single clicks. These differences were believed to be the result of anatomical modifications, but our poor understanding of the mechanism that produces these sounds greatly restricts speculation and led these two researchers to conclude that it would be preferable to place all echolocating swiftlets in a single genus. C. T. Collins and R. Murphy considered that "a well developed kinesthetic or spatial memory would seem to be a necessary supplement to the echolocation capacities of swiftlets".

A distinguishing feature of all members of the subfamily Apodinae, except probably the needletails, is the use of saliva as a binding mechanism for nesting material. In the Edible-nest Swiftlet (*Aerodramus fuciphagus*) this is taken to extremes, saliva being used for the construction of the whole nest. In the breeding season, the sublingual glands of both sexes are greatly enlarged to facilitate the production of large amounts of this "nest-cement". This salivary glue is composed largely of glycoproteins, and holds remarkable properties that make it attractive to the human world in various ways (see Relationship with Man).

The plumages of all swifts are certainly dull, although there are exceptions to the black or brown theme. In two closely related Neotropical species, the Chestnut-collared Swift (*Cypseloides rutilus*) and the Tepui Swift (*Cypseloides phelpsi*), all adult males and some adult females have a bright chestnut-reddish throat. Many species are decidedly glossy in plumage. This reaches its extreme

in certain members of the Chaeturini, most notably the Philippine Spinetail (*Mearnsia picina*), the Purple Needletail (*Hirundapus celebensis*) and the White-throated Needletail, and also in the Collocaliini in the aptly named Glossy Swiftlet (*Collocalia esculenta*). One form of the last of these, *amethystina* from Waigeo Island, has brilliantly dark violet-blue upperparts. Nearly all swifts, however, show at least a slight gloss in fresh plumage. It is hard to determine the function of these feather glosses, although it is interesting to note that they are exhibited also by most hirundines. Perhaps the increased albedo of glossy feathers is important in protecting the plumage, which is so constantly exposed to direct light during aerial foraging, or could it be that the gloss has some effect on thermoregulation or aerodynamics?

In many migratory species, moult is completed on the wintering grounds, after migration. In some species, it starts before the onset of migration and is then suspended during migration, being completed on arrival in the tropics. Perhaps the most remarkable fact relating to the moult of swifts comes from the Common Swift, and presumably applies to other temperate-breeding species as well. After fledging, juvenile Common Swifts do not undergo a complete moult until their second winter in Africa; as a result, their remiges will be used for one and a half years before being replaced. In addition, moulting Common Swifts do not always replace the outermost primary on each wing, and therefore these feathers might not be replaced for up to two and a half years. When moult is recommenced in such individuals, second-winter or otherwise, it commences with the outermost primary.

Some swifts, notably in the genus *Chaetura*, moult during the breeding season. Studies of breeding Vaux's Swifts (*Chaetura vauxi*) show that moult strategies are individually variable. Some Vaux's Swifts in Oregon, USA, were recorded using communal roosts for part of each day in August and September, presumably while building up their reserves for migration and continuing their moult. The Chimney Swift finishes its primary moult by early October, while in the first stages of its migration.

Resident species may wait until the end of the breeding season before moulting, although some species of swiftlet that have extended breeding seasons employ similarly drawn-out moult strategies. The White-throated Swift (*Aeronautes saxatalis*) is unusual among migratory species in that it moults during the breeding

season, perhaps because in its relatively northern wintering grounds the period of peak food abundance is over before the swift arrives.

Habitat

Swifts are highly specialized feeders and breeders, requiring foraging areas with adequate concentrations of aerial plankton, while at the same time needing ease of access to their particular breeding and roosting sites. These two habitat characteristics are sometimes exclusive of one another and require that daily movements, on various scales, be undertaken. Those species that lay relatively large clutches, and whose chicks therefore have the most rapid growth rates, need to forage closest to the nest, while those with smaller clutches and slower rates of growth can forage at greater distances. Thus, for swifts generally, and for the former group in particular, the concept of nesting habitat is often restricted to the immediate vicinity of the nest-site (see Breeding), since the vulnerability of all swifts when not on the wing has led to nest-site security, especially inaccessibility to terrestrial predators, being of prime concern.

Swift habitat in its simplest expression is a site where prey can be taken. For many species, this means regular journeys well away from the breeding or roosting area. This is less of a problem for the large species than for the smaller ones. In the cordilleras of northern Venezuela, around the famous Henri Pittier National Park, the large and rapidly moving White-collared Swift (*Streptoprocne zonaris*) is able to utilize the wide range of habitats available within several kilometres of the highlands where it nests and roosts. When rain falls in the highlands, these swifts will move into the adjacent lowlands to feed, even foraging at building height over the streets of nearby cities.

The well-studied Common Swift has perhaps the most catholic habitat preferences of any swift. In the breeding season it is found from north-west Africa and the Middle East north to Arctic parts of Scandinavia and Russia, and sweeping east to the Pacific. Across this enormous breeding range it occurs in such disparate habitats as desert, Mediterranean scrub, steppe, farmland, suburbia and the centres of great cities. Wintering in sub-Saharan Africa, it can be seen over any habitat, even including forest, which is shunned by many swifts. This species, feeding from rooftop level to great

Plumage coloration is particularly drab amongst the Apodidae, and almost all species are covered in varying tones of blackish, dark brown or paler dull brown, sometimes with bluish or greenish gloss. Apart from two *Cypseloides* species with rufous throats and collars, the overall dark colouring is punctuated only by areas of white or whitish, most typically on the throat or rump, but sometimes elsewhere on the underparts, or on the forehead. The White-throated Swift has rather extensive white on its underparts, and is notable in showing a distinctive white trailing edge to the wing, most heavily marked on the secondaries.

Animals Animals]

Having channeled their evolutionary energies towards success in a highly aerial lifestyle, swifts are not adept at moving about on the ground. Nevertheless, their small feet are surprisingly strong and, with the sharp claws, are well designed to help the birds perch on vertical surfaces, though they are not suitable for grasping horizontal branches.

When clinging to a steep rock face, like this Alpine Swift, or to a vertical wall, like this Common Swift, the birds often use the tail to gain greater purchase, as also occurs in some tree-climbing families of bird, such as the woodpeckers (Picidae), woodcreepers (Dendrocolaptidae) and treecreepers (Certhiidae).

Indeed, members of the spintail tribe, Chaeturini, show a similar modification of the tail feathers as is to be found in these families, although swifts do not clamber about the surface in the same way, tending simply to stay put where they are perched. Swifts' clumsiness in moving about on the ground would make them ideal targets for terrestrial predators, which explains their habit of perching in such inaccessible sites. Visible on these two birds is the round-headed, broad-faced appearance, brought about in part by the birds' wide gape, which helps in their aerial foraging for insects, though the bill itself is short and rather weak-looking.

heights, typifies above all others the adaptive success of the family. If the food supply is adequate and suitable nesting sites exist, it will breed; and if adverse weather causes a temporary lack of suitable food, it will travel long distances to avoid such conditions before returning to its nest (see Movements).

Water is an important requirement for all life, but it is fundamental in the breeding cycle of many insect species. As a consequence, swifts are seldom found far from it. This is especially evident with species such as the Pallid and White-throated Swifts which penetrate arid interior habitats. The former is found around many oases in the central Sahara, while the latter, although breeding in the arid south-central USA and northern Mexico, always has meadowland, typically damp, within easy reach of its nesting sites. Water reaches its maximum prominence in the habitats of the largely waterfall-dependent New World Cypseloidinae and the South-east Asian Waterfall Swift. Again, however, both of these taxa occur over a great range of habitats adjacent to their secure roosting and breeding sites and presumably benefit from, among other things, the ease with which nesting materials such as liverworts and mosses can be gathered.

Some species have more specific habitat requirements. The palm-dependent genera *Cypsiurus* and *Tachornis* are seldom found far from their arboreal hosts, and the charismatic Böhm's Spintail is often found near baobabs (*Adansonia digitata*). Some swifts occur exclusively in and around forest and have shown little ability to adapt to the fragmentation of this habitat. The classic example must be Sabine's Spintail (*Rhaphidura sabini*), with its near-continuous distribution in the West African forest belt and relict East African outposts such as the forest of Kakamega in west Kenya.

General Habits

No group of birds is so fundamentally adapted to an aerial existence as the Apodidae. This has a profound effect upon all aspects of their lives.

Although superficially similar to the swallows and martins (Hirundinidae), and long associated with them in classifications, swifts belong to a quite different branch within the avian tree, and most of the similarities can be put down to convergent evolution for a highly aerial lifestyle. Most swifts can readily be distinguished by their long, narrow wings, which are swept back like sickles, and which indeed slash through the air to similar effect. It is perhaps the swifts' dashing style of flight which best separates them from the hirundinids. The White-rumped, Pallid, Pacific and Alpine Swifts all show slight variations on the "typical-swift" silhouette of the Apodini.

Most swifts are highly gregarious throughout the year, frequently exploiting short-term concentrations of food. They often form large mixed flocks with other swift species and other aerial feeders, primarily hirundines. Resource-partitioning occurs within such mixed feeding flocks as a result of size-specific and perhaps taxon-specific preferences in diet.

Exploitation of the aerial feeding space is clearly of great importance in flocking behaviour, but it also confers other advantages. Several raptor species regularly take swifts, not least some falcons (Falconidae). In North America White-throated Swifts are often caught by Peregrine Falcons (*Falco peregrinus*), while in the south-western Cape, South Africa, Little Swifts (*Apus affinis*)

accounted for 19% of 121 prey items taken by Eurasian Hobbies (*Falco subbuteo*). Even the large and powerful Alpine Swift has been taken by the Sooty Falcon (*Falco concolor*), while swiftlets are commonly included in the diet of Bat Hawks (*Macheiramphus alcinus*), which have been persecuted as a consequence, due to the economic importance of the swiftlets (see Relationship with Man). Swifts frequently mob small raptors while emitting alarm calls and undertaking rapid evasive movements.

The Common Swift also forms large flocks before migration, although actual migration is typically undertaken in smaller groups. Non-breeding and breeding birds leave colonies at the same time. Indeed, the cohesion of the colony may sometimes

Waterfalls are favoured by several apodids, such as the Great Dusky Swift. Some species are merely seen foraging in the vicinity, but others roost and nest beside the falls or actually behind the curtain of water.

When admiring the awe-inspiring power of the relentless cascades of water, it seems scarcely conceivable that such small birds should take such risks, but it would appear that they seldom come to harm, although there are rare records of birds being washed downstream. Nevertheless, if there is a rapid increase in water flow during the breeding season, the birds are sometimes unable to reach their nests.

DRK]

transcend species boundaries, as screaming parties from mixed colonies of Common and Pallid Swifts appear to be directed at groups of swifts from other, "rival" colonies.

At night most swifts rest, although parents at the nest continue to incubate their eggs or brood their young. Chattering can be heard all night from the colonies of certain species, and it is likely that no swifts are "heavy sleepers". Resident populations often roost at the nesting site, and swiftlets of several species spend the whole year roosting in or close to their nests. A good deal of roosting behaviour is, however, gregarious and use of roosts is not confined to those adults and their young that have used the site for breeding. One chimney nest-site of Vaux's Swifts contained a post-breeding roost of 16 birds, of which only one of 11 young present had been fledged at the site. Interestingly, D. Lack's classic Oxford study suggested that young Common Swifts did not return to the nest after fledging. However, fledglings of several species will return to roost at the nest with the adults, and in some species to rest during the day, for up to a week after their first flights.

The celebrated aerial roosting of swifts has been proved, with certainty, only for the Common Swift. It may also be practised by Pallid and Alpine Swifts, since these species, like the Common Swift, have exceptionally refined oxygen-collecting ability; this results from concentrations of haemoglobin surpassed only by hummingbirds and akin to those found in montane species living at over 2500 m. On the breeding grounds, aerial roosting is particularly frequent in first-year birds and typically involves occupation of the airspace at an elevation of 1000-2000 m, though roosting to 3000 m has been recorded. Aerial-roosting flocks initially involve screaming parties, which become close-circling, rapidly rising groups. In western Europe, this behaviour occurs in late evening in the warmest weather from the end of May; in periods of bad weather, roosting by non-breeders in potential nest-sites has been noted. As the breeding season progresses, breeding adults may also be found in the aerial-roosting flocks. Some newly fledged individuals are also believed to roost in this manner. Altitude is maintained by slow wingbeats with intermittent gliding, typically flying into the wind, which provides lift. This behaviour may prove to be frequent throughout the year. The Common Swift will also roost on walls, in tree hollows, on tree trunks or even on the outer foliage.

The length of the roosting period is subject to a number of variables. These can be broadly grouped as climatic, such as light

intensity and temperature, and therefore geographical location; age-related; and behavioural, including breeding and migratory status. All these factors are ultimately related to food supply and energetics.

Swifts are relatively late risers from terrestrial roosting sites, presumably owing to the diurnal pattern of prey density. The most northerly Common Swift populations roost longer after sunrise (which occurs earlier) than do those farther south. Equally, better weather brings an earlier start to the day's activities than poor weather, while birds with young roost later than those without young, presumably to take advantage of maximal prey densities while conserving adult fitness. Prior to their migration, temperate species extend the length of this "lie-in". Little Swifts are mainly early and late feeders and spend much of each day in pairs at their nests, to some extent presumably sheltering from the hottest period of the day. In this species, roosting time is photosensitive, with birds from poorly lit colonies roosting on average 10-13 minutes later than those from well-lit colonies.

The roosting behaviour of Chimney Swifts studied in Illinois, USA, has also been proved to be influenced by climatic variables. Swifts stayed in the roost-site longer and re-entered it earlier on cold or rainy days, and those with low wind turbulence. All these environmental variables affect the abundance of aerial insects. On average, these swifts left their communal nesting chimneys 11 minutes before sunrise in flocks of 70 birds, and re-entered the roost 20 minutes after sunset in flocks with a mean of 83 birds. The roosts consisted mainly of non-breeders, with up to 300 in a single chimney. One site in Portland, Oregon (USA), holds an autumn roost of Vaux's Swifts that numbers an estimated 20,000-30,000 individuals. Such pre-migratory roosts may help with conservation of fat reserves and even moult in some species. Indeed, it has been observed that Chimney Swifts can increase their body weight by up to 51% prior to autumn migration.

A pair of White-chinned Swifts has been observed roosting, the partners side by side, in the constant spray of a waterfall close to a nest. White-collared Swifts roost in similar situations, invariably attempting to stop others of their species from roosting near them by raising one or both wings, depending on whether both pair-members are present, to prevent "intruders" from landing. Perhaps the most intriguing roosting behaviour observed by M. Marín and F. G. Stiles, in their study of Cypseloidinae species, involved a pair of Spot-fronted Swifts one of which clung

Great Dusky Swifts typically nest on horizontal ledges close to a waterfall, or sometimes actually behind it. This choice of nest-site clearly gives the birds considerable protection from predators. Here hundreds of birds can be seen clinging, almost bat-like to the damp rock faces between two branches of the waterfall, their pale heads appearing white from a distance. The swifts also roost around waterfalls, again presumably for protection, and during the day they make feeding forays out over the canopy of the forest nearby. The Great Dusky Swift is locally common in suitable sites, from the lowlands to about 1000 m, mainly in Argentina, Brazil and Bolivia, and it may also occur in Peru and, more rarely, in Paraguay. It may be threatened in places by dam building along some of its rivers.

[*Cypseloides senex*,
Falls of Iguazú, Argentina.
Photo: Günter Ziesler]

Clustering close together and clinging on to the rock face with their sharp claws, these Great Dusky Swifts are protected from the direct spray by an overhang in the rock. Nests located at such sites are virtually impregnable to any potential predators. There tend to be plenty of mosses and liverworts nearby, and these the swifts collect to construct their nests. The nest itself, made of soft plant matter and stuck together with saliva, is usually built at the top of a cleft in the rock. It is a raised structure, exposed to the daylight, an unusual case amongst the Apodidae. The adults do not appear to mind being moistened by the spray of the waterfalls, but the nestlings are protected from chilling in these humid sites by a thick coat of down.

to a tiny ledge of rock, its wings hanging loosely, while its mate was "clinging to the shoulder or upper back of the first, with its tail also fully spread bracing it against the first"!

In particularly cold weather, swifts employ a number of warmth-saving strategies. Roosting pairs of Common Swifts ruffle their feathers, arch the back and often roost one on top of the other. Huddled groups have been noted in several species. Non-breeding Alpine Swifts roost on the outside wall of colonies, forming dense writhing clusters in response to cold weather. A flock of migrating Chimney Swifts roosting on the trunks of two palm trees formed a dense layer, with individuals touching, though not on top of each other as was the case in an open noc-

turnal roost of migrating Vaux's Swifts, when the air temperature was 25°C.

Radio-tracking technology has been used to investigate the roosting habits of wintering White-throated Needletails. One was tracked back to a low strip of sclerophyll woodland in the Gongiberoo Range, Australia, where it probably roosted in a hollow tree. Such sites are likely to be traditional, and this bird returned to the same place, with other needletails, on consecutive nights.

During unusually bad weather, swifts may form daytime roosts, presumably to rest and conserve heat. A particularly impressive instance was recorded after a period of cold weather in Morocco, when three dense clusters of Alpine Swifts, totalling some 350 individuals, were found clinging to a sheltered part of the city wall in Fez.

It has also been established that the White-throated Swift and, from available evidence, almost certainly the White-throated Needletail, too, can enter a torpid state similar to that well documented for certain nightjars, most famously the Common Poorwill (*Phalaenoptilus nuttallii*) of North America (see page 309). The needletail's temperature was recorded dropping from 38.5°C to 28°C, only 3°C above ambient, over two hours during the night, and in the morning it returned rapidly to 38°C in just a few minutes. Strongly variable body temperature has also been recorded in other swifts. Further data may prove such a phenomenon to be widespread in the family.

Roosting in mixed-species assemblages has been recorded, and is particularly common among the Cypseloidinae at waterfall sites. Furthermore, the Chimney Swift is one of several North American species from a variety of families that apparently occur in the roosts of Common Starlings (*Sturnus vulgaris*) and Common Grackles (*Quiscalus quiscula*).

Many aerial displays have been studied but, as R. B. Fischer observed in the 1950's, most swift displays, being aerial, appear destined to remain poorly understood. Fischer's work on Chimney Swifts revealed that aerial displays were affected by precipitation and, in particular, low temperatures; cessation of display as a result of such climatic conditions is most likely to occur early in the season. In his studies of Chimney Swift display, he recognized two distinct phases which he called "Early" and "Later". The former began when the swifts returned for the summer, flying in loose associations of 4-7 individuals without feed-

ing. Pairs would often break from these larger groups and fly together. Speculation suggested that this behaviour was in preparation for the synchronized behaviour which would ensure breeding success later. The second phase is characterized by "trio-flying", in which two males chase a female between various physical obstructions, all three birds constantly calling loudly. These flights may exceed five minutes in duration and at their peak may involve ascents to 150 m at increasing distance from the nearest nest-site. Rarely, one of the pursuing males will physically attack the other. One feature of this display is a sharp chipping call that was initially believed to be produced by the female, although later observations seemed to contradict this. However, it is interesting to speculate that, as with the Common Swift, a sexual shift in the tone of the call may exist in the Chimney Swift, thereby accounting for this apparent difference.

Various similar chasing displays are a feature of the behaviour of many swifts. Paired Short-tailed Swifts fly parallel to each other with extravagantly slow wingbeats while slowly uttering ticking notes, and White-collared, White-chinned and Chestnut-collared Swifts have been observed performing chasing displays similar to those documented for Chimney Swifts. A presumed female White-collared Swift was chased by up to three males before rejoining larger flocks. During chases, a posture known as "V-ing", with both wings held high above the body, may occur in power dives. Fischer also recognized a V-ing display when the following individual in a pair suddenly snaps into position; this may or may not be performed by the leading bird, too. It can be noted in trio-flying, but not during hot pursuit. This behaviour reaches its greatest expression in established pairs. Many other species produce similar displays. In Common Swifts the procedure is more pronounced, and is often repeated several times, the wings meeting over the back and producing an audible clap before being rapidly lowered beneath the body to meet again.

Communal screaming by fast-moving flocks rushing around the area of the colony is a familiar feature of a number of *Apus* species. In Common Swifts these displays are most frequent in the evening, though by no means restricted to this period, and often involve the whole colony, with individuals in nest-holes joining in the calling and often leaving their nests to participate.

The display is typically initiated by a single calling individual rapidly approaching the colony. It can take only a few seconds but consists of five or six circuits and be repeated quickly several times in succession. Before migration, these displays sometimes involve individuals from several colonies.

In this family, both the nests and the individual birds play host to a wide variety of invertebrate parasites. In Africa, the main species are hippoboscids flies (*Crataerina*, *Pseudolynchia*, *Ornithomya*), feather-lice (*Dennyus*, *Eureum*) and ticks (*Lelaptidae*, *Proctophyllodidae*, *Analgesidae*, *Eustathiidae*). Some of these swift parasites are endemic to particular groups, suggesting a considerable degree of co-evolution. As anyone who has handled swifts can testify, heavy parasitic infestations are not uncommon. The reasons for the unusually heavy parasite loads carried by this family may be related to preening difficulties caused by extreme anatomical adaptation to an aerial way of life.

Voice

Swifts are very vocal. Their calls are most frequently given during the breeding season, when the greatest variety can be heard. Although the calls of most swifts are superficially similar, recent studies have given researchers important insights into aspects of their behaviour and taxonomy.

This is nowhere more apparent than in the case of the high-pitched screaming of the Common Swift, such a familiar sound in Europe, where it typifies the summer to ornithologists and the general public alike. The excellent study of E. Kaiser has revealed that males utter a "ree" scream and females a high-pitched "swee". It has long been known that the pair-members duet to produce the distinctive "swee-ree" call, but Kaiser's work has enabled him to solve many behavioural problems. For instance, the screaming of non-breeding birds outside nest-holes which they are prospecting allows occupants to indicate that both of the pair are present; if the prospector still chooses to enter the nest, it will be attacked by the same-sex member of the pair. This clearly has implications for a whole range of breeding issues, and most importantly for pair formation. Kaiser has speculated that further research will show that

Swifts are in general highly gregarious in most of their activities, regularly foraging, nesting and roosting in the company of conspecifics. One of the species most famous for its communal roosts is Vaux's Swift, and at one roost-site in Portland, Oregon (USA), an estimated 20,000-30,000 birds gather together every autumn, using the site for several weeks at a time. The birds shown here, at a Mexican site, were part of a large group of Vaux's Swifts roosting in a well cut into the limestone bedrock.

[*Chaetura vauxi gaumeri*, Cozumel Island, Mexico. Photo: Robert Behrstock]

The Mottled Spinetail is particularly closely associated with baobab (*Adansonia digitata*) trees in dry woodland, although it can be seen in a range of woodland types. It normally roosts in baobabs, typically in groups of 5-11 birds, though over 100 birds have been recorded at such a site in Angola. The birds seen here were roosting inside a huge baobab tree of great antiquity, estimated as being some 2500 years old.

[*Telecanthura ussheri benguellensis*, Gona-re-zhou Game Reserve, Zimbabwe. Photo: Mark Homann]

all other species in the family can be sexed using call, at least those that are sexually monochromatic or that nest in the dark.

Perhaps the most fascinating of all vocal adaptations are the echolocating calls of certain swiftlets. These calls, which are paralleled only in the Neotropical Oilbird (*Steatornis caripensis*), were studied in a series of experiments by Medway and Pye (see Morphological Aspects). The echolocating calls of swiftlets are within the human spectrum of hearing and are harsh trills that accelerate and decelerate; they have been likened to running one's finger across the teeth of a comb. Unlike bats, echolocating

swiftlets lack the acuity to feed on insects using echolocation alone, and sight remains their primary sense for capturing prey. Echolocation does, however, enable swiftlets to navigate within deep cave systems and perhaps to feed later into the evening than other aerial bird species. It is possible that this has helped them to compete in a niche typically occupied by free-tailed bats (*Molossidae*), as this family of bats is poorly represented in those areas of the tropics where the swiftlets are present.

Two species in the Cypseloidinae, the White-chinned and Spot-fronted Swifts, have been recorded uttering calls that may have

As their common name suggests, Chimney Swifts are famed for nesting and roosting in chimneys, but they will also use natural sites, as here, where the birds are returning to roost in the hollow bole of a broken beech tree; it is nowadays rare to find this species nesting in such a site. Research has shown that the weather conditions can have a significant effect on the birds' behaviour at their roost. On cold or damp days, they tend to remain in the roost-site longer in the morning, and return to it earlier in the evening, probably in connection with fluctuations in the abundance of the aerial insects they feed on.

[*Chaetura pelagica*, Ohio, USA. Photos: S. Maslowski/FLPA]

The White-collared Swift is found from Mexico south to Brazil and Bolivia. Within this extensive range, it occurs in a fair variety of habitats from sea-level up to over 4000 m, from the coast up into the mountains. It generally nests in damp caves, typically behind waterfalls, where it may breed alongside Great Dusky Swifts (*Cypseloides senex*). The nest is a small pad of mud and plant material, with mosses and liverworts. In many areas breeding begins late in the dry season, timed so that the young are in the nest at a time when the insect supply is plentiful early in the wet season.

[*Streptoprocne zonaris bouchellii*,
River Tiribí, Costa Rica.
Photo: Manuel Marín]

echolocating implications. The poorly studied Scarce Swift (*Schoutedenapus myoptilus*) has also been noted as having a call resembling that of the swiftlets, and it is tempting to speculate that echolocation ability may extend beyond that group. When one considers the crepuscular feeding and cave-dwelling habits, both actual and analogous, of many swift species, the high-frequency, high-pitched trills of most swifts cry out for further examination.

Sounds akin to the drumming of snipes (*Gallinago*), produced by allowing certain feathers to vibrate, have been recorded in the Apodidae. Male Common Swifts have been noted producing brief "trrr...t" sounds while V-ing after aerial copulation, while Mottled Swifts (*Tachymarptis aequatorialis*) have been observed spreading the tail and moving it horizontally until the outer rectrix nearly touched the wing, where it vibrated, making a loud "prrrpt-prrrpt-prrrpt". This occurred while the birds were diving to the surface of a reservoir to drink.

Food and Feeding

All swifts feed exclusively on insects and spiders, taken mainly in the air. Their diets have been studied by analyses of stomach contents, droppings, pellets or food boluses, and all methods have revealed the importance of Hymenoptera (bees, wasps, ants), Diptera (true flies), Hemiptera (true bugs) and Coleoptera (beetles). Stinging insects are generally avoided, while mimics of stinging insects are taken. Work in Zaire has shown that Common Swifts feed almost entirely on stingless honeybee drones when foraging around hives. Nevertheless, an Alpine Swift was found, when examined, to have a number of stings lodged in its throat.

It has been suggested that smaller swifts typically take a greater variety of relatively small prey, while larger swifts tend to consume a larger number of a few species. This is due in no small part to the ability of larger species to take particular advan-

tage of swarming insects as a result of their extensive foraging areas, which may allow them to exploit a number of climatic zones in a short period of time. Indeed, this ability has led to a specialization among larger species generally to exploit concentrations of single species of insect. For instance, 800 winged ants were recorded in the stomach of a Venezuelan White-collared Swift, and 681 fire ants (*Solenopsis geminata*) were found in a single White-naped Swift (*Streptoprocne semicollaris*). Smaller swifts also feed on swarming insects, however, and data from prey analyses of many smaller species show that they will take advantage of temporarily bountiful prey sources. It is their more limited foraging ranges that reduce their consumption of such prey. These limited ranges reflect the need to stay close to larger clutches and comparatively many rapidly growing nestlings that require frequent feeding; in many of the larger swifts, with fewer, slowly growing offspring, the converse is true.

White-collared Swifts exploit the food sources disturbed by seasonal fires in South America. Even more opportunistic feeding behaviour was noted in southern Africa by W. R. J. Dean, who was followed for over 50 minutes by up to three Alpine Swifts; these caught cicadas (*Cicadidae*) that he flushed from around him as he walked through shrubland. White-throated Swifts have been noted following a combine harvester, apparently taking disturbed insects.

Although all swifts are selective with regard to both prey size and prey species, their gape size, which is essentially dependent on absolute size, remains a limiting factor. This helps reduce interspecific competition in much the same way as aerial stratification does in mixed flocks. The difficulty of comparing the diet of one species with that of another is confounded by geographical variation in diet. In north-west Italy, Pallid Swifts have been shown to take smaller prey with a greater number of dipterans and hymenopterans compared with Common Swifts, which took more aphids and coleopterans. At Gibraltar, on the other hand, Pallid Swifts have been noted taking significantly larger prey than

The swiftlets, comprising the genera *Hydrochous*, *Collocalia* and *Aerodramus*, form an assemblage of small, very similar, rather nondescript species. The taxonomy of this group is very confused, with uncertainty and dispute at generic, specific and subspecific levels. The forms currently split off into the genus *Aerodramus*, including the Australian Swiftlet, are amongst the drabest of the lot, but they are certainly not the least interesting. These are the famous cave-nesting forms that navigate amidst the gloom of their caves by means of echolocation, uttering a stream of metallic clicks as they fly. Their feats of navigation in the dark are all the more remarkable because the birds nest in sizeable colonies, with many nests clustered together in a small area, so that not only do the birds have to steer clear of the cave walls and projecting outcrops, but they must also avoid all of their neighbours flying busily around the nests. Australian Swiftlets breed in caves, or between large boulders or in gorges, where they typically form dense colonies.

ANT/NHPA]

Common Swifts. One study of Pallid Swifts in Morocco revealed a relatively high proportion of spiders, although it has been suggested that this might have been just a manifestation of the comparatively brief period over which samples were collected.

Seasonal prey differences may also prove to be acute in some species, though a Costa Rican study showed that there was no significant difference between the types of prey taken by Band-rumped Swifts (*Chaetura spinicauda*) in the wet season and those taken in the dry season. Bolus-content analysis in Common Swifts indicates that the decline of mass insect swarmings at the end of the breeding season leads to a sharp fall in the numbers of many nutritious insect species within the birds' foraging airspace, and to a subsequent increase in the number of beetles taken. Differences between the diets of adults and nestlings may also contribute to seasonal variations in prey taken.

A radio-tagging study of the breeding-season diet of Vaux's Swifts revealed that the adults foraged up to 5.4 km from their nests, primarily over land, with water used less frequently. Perhaps surprisingly, no variation in diet was recorded between the five study sites or during the course of the day. The 233 boluses examined contained the astonishing total of 24,133 spiders and insects.

Generally, the larger the swift is, the smaller the number of prey items it takes, with a corresponding increase in prey size. The Common Swift averages about 300-500 prey items per bolus, compared with 156-220 in the larger Alpine Swift. Studies of prey size in three *Cypseloides* swifts showed that most of the prey taken by the Spot-fronted Swift, the smallest species, was 1-4 mm long, compared with a general range of 8-11 mm for the Black Swift (*Cypseloides niger*), the largest species. Interestingly, the intermediate species, the White-chinned Swift, showed a bimodal pattern, with peaks of 41.3% of prey items in the 4-5 mm range and 38.4% around 11 mm long.

The above examples show that swifts, far from being the random "vacuum cleaners" of folk biology, are actually exact selectors of prey. Indeed, White-collared Swifts have been observed to be particularly choosy when feeding on leaf-cutter ant queens, as they discard the thin cephalothorax in the process of cutting off the fat abdomen. Many species swallow such indigestible elements and expel them as pellets. Several studies comparing the diets of swift species in areas where traps have been used to sample the insect fauna have found that the different species' diets do not translate exactly into the composition of insect life available.

Although most swifts lack the high manoeuvrability of hirundines, some do feed close to the canopy. In perhaps the greatest divergence from typical apodid foraging, hovering Papuan Spinetails (*Mearnsia novaeguineae*), Grey-rumped Swifts (*Chaetura cinereiventris*) and Chimney Swifts have been noted apparently taking food from foliage, and it has been suggested

that such behaviour may be more common and widespread within the family than is currently suspected. A flock of Chimney Swifts was seen feeding by diving basically tail-first through openings in the upper storey of a tree, in the manner in which they enter chimneys, fluttering briefly and gleaning insects from leaves lower down the canopy. Even more surprisingly, an individual of that species was once recorded apparently attempting to take a dragonfly (Odonata) from a Purple Martin (*Progne subis*), which was trying to position the insect in its mouth before swallowing it.

The Glossy Swiftlet has been shown to be as manoeuvrable as sympatric hirundines, allowing it to feed very close to the tree canopy. Its diet has been found to contain a larger proportion of homopterans and coleopterans than those of other tropical swifts, its foraging technique giving access to prey items that are generally unavailable to these other species. Even caterpillars have featured in the Glossy Swiftlet's diet.

Most swift species feed significantly higher than tree-top level, although, at least in Europe, the reduction in insect numbers above 100 m enforces a typical upper limit. Competition among various swift species, and with other aerial feeders, is generally avoided by differentiation in prey size and also by selection of different altitudinal strata. A study in Ecuador showed that, when similar species were foraging within the same column of air, the larger ones would occupy the higher strata. Similar results were obtained from Niah caves in Sarawak, where there was vertical stratification of three swiftlet species, and to some extent from Kariba in Zimbabwe, where the larger species generally fed in the higher strata.

Feeding is often concentrated during certain times of the day. For example, the Waterfall Swift is predominantly a crepuscular feeder, and several cave-dwelling species apparently feed late into the evening, thanks to their echolocating abilities (see Voice). Little Swifts tend to rest in the heat of the day (see General Habits), feeding both earlier and later. Truly nocturnal feeding has been recorded for the Alpine Swift and the Indian Swiftlet (*Aerodramus unicolor*), both of which have been seen exploiting the food source from around lights, while Alpine Swifts may apparently feed in total darkness. It is possible that nocturnal feeding is more widespread in the family than is currently thought.

Swifts drink regularly, by dropping to the surface of a body of water and dipping in the lower mandible. Surprisingly small areas of water are used for this purpose. Insects are also taken from the water's surface.

Breeding

Swifts generally pair for long periods and are apparently monogamous. A study of Pallid Swifts in Italy showed that mate

The fact that swifts are so aerially orientated and comparatively inexpert on the ground means that drinking, like many other activities, is performed on the wing, as demonstrated by this White-throated Needletail. A bird will skim down low over a stretch of water and dip its head to take a mouthful while in full flight, before rising up and often returning to repeat the process several times.

[*Hirundapus caudacutus*, Daclin, Heilongjiang, China.
Photos: Roland Seitre/Bios]

Swiftlets typically breed in large, densely packed colonies, with a great many nests clustered close together, as in this colony of Glossy Swiftlets in northern Borneo. Unlike those swiftlets placed in the genus *Aerodramus*, this widespread and common species apparently has no ability to echolocate, which is consistent with its general avoidance of the dark interiors of caves, its favoured nest-sites including cave entrances, cliff overhangs, hollow trees, and also buildings, always in places where there is sufficient daylight. In this species, each nest is a small cup made of a mixture of small roots, mosses and lichens, glued tightly to a vertical surface using the birds' saliva.

In contrast to these habits, many members of *Aerodramus* commonly nest in partial or total darkness, where they navigate by means of echolocation. Also, many make extensive use of saliva in forming the actual nest itself, and in some cases nests may even be constructed exclusively of saliva. Such nests are the most highly valued for the multi-million-dollar bird's-nest-soup business, a trade which has had serious impact on swiftlet populations in many areas.

Many swifts have adapted their ancestral habits to take advantage of the relatively new nest-sites available in man's constructions. Thus, some nest under the eaves of bridges, while many occupy suitable sites under the roofs of houses. This is the case of the Little Swift and also of its eastern counterpart, the House Swift (*Apus nipalensis*), which may actually be conspecific. These species form small, rather untidy agglomerations of bag-like nests constructed mainly of grass and feathers, cemented together with saliva, each with a small tunnel or slit as its entrance.

and nest-site fidelity were much lower than recorded for other European swifts. The advantage gained by the ability of faithful pairs to nest earlier than non-faithful pairs was, however, insufficient to manifest itself in significantly different breeding success. Paired individuals of many tropical species may stay together all year round, and some swiftlets are known to roost in pairs at the nest-site throughout the year. In the case of migrant species, bonds must be renewed annually. Among Common Swifts, for example, partners remain together throughout the tenancy of a nest-hole. Pair-bonding starts with non-breeding first-summer birds, which will go so far as to occupy a nest-site and build a nest, which they will defend in subsequent years.

For all swifts, the breeding season is related, primarily, to the abundance of insect life. This simple fact has a great impact on breeding biology. In the tropics it means that breeding coincides with the wet season, while in temperate zones summer breeding is invariably the rule. The length of time available for breeding has a profound effect on many aspects of breeding biology. Seasons are shorter for species that breed in the highest latitudes than for those breeding in climates which can support adequate insect populations for longer periods. For example, the Common Swift has a single clutch, while the more southerly Pallid Swift can produce two clutches. Production of two clutches is commonest in the tropics and has been reported for a number of species. In the case of the wide-ranging Little Swift, distinct breeding seasons are generally recorded in areas with the most marked seasonality, whereas in some equatorial regions year-round breeding can occur.

Studies of swiftlets breeding in the vast limestone caverns of Niah, in Sarawak, indicated that even in seemingly seasonless equatorial climates variations in the timing of breeding occur. Although the majority of Black-nest and Mossy-nest Swiftlets (*Aerodramus salangana*) breed between September and April, some breed throughout the year, as the climate is never too harsh. Glossy Swiftlets have three seasons within a year, and it was speculated that varying day-length might serve as a regulating mechanism. Observations of the number of swiftlets returning to and leaving from the caves suggested a degree of variation in food supply through the year, not least during the monsoon, when persistent downpours cause frequent prey shortages.

Although the broadly similar breeding seasons of the Black-nest and Mossy-nest Swiftlets suggest very similar biologies, the

former feeds at higher elevations than the latter and would perhaps be more likely to suffer from comparatively irregular food supplies. The Black-nest Swiftlet shows a number of adaptations to this dietary dilemma. Both the single egg and the hatchling can withstand long periods without brooding, with consequent temperature reductions, and the fledging period is protracted; in addition, both adults and juveniles can tolerate periods of relative starvation.

For the genus *Cypseloides*, the wet season brings not only abundant food, but also nesting material and suitable conditions for it to adhere to a substrate. Nesting therefore starts anything from one to three months after the beginning of the wet season. In the related genus *Streptoprocne*, the White-collared Swift begins laying late in the dry season, so that the young benefit from early wet-season insect abundance. On Penang, off the west coast of the Malay Peninsula, the Edible-nest Swiftlet's breeding season appears to show a very limited relationship with rainfall, suggesting a fairly constant supply of insect prey; indeed, the majority of eggs hatch in the dry season.

Swifts utilize a wide range of nest-sites. Most are in dark places, and many swifts in fact nest in pitch-black conditions. This is nowhere more apparent than in the echolocating swiftlets, which use their most distinctive sensory attribute to fly considerable distances into the total darkness of some cave systems. Although Common and Pallid Swifts generally choose holes as the safest type of nest-site, the eaves of buildings are often preferred, and the usage of sites probably varies with local availability. Nowadays the Common Swift nests almost exclusively in man-made structures.

Most species have precise nesting requirements. These have been investigated in great detail for the North American Black Swift, and they indicate why some swifts are often absent from what appears to be suitable habitat. Studies have revealed six constant features: water; inaccessibility; darkness; unobstructed flyways immediately in front of the nest; rock niches on which to build; and usually high relief. Clear access to the nest entrance is an important feature for many species. For example, the African Palm-swift (*Cypsiurus parvus*) has been found to require a flyway of 40 m; and the Mottled Swift nests only in dry granite sites with at least 6 m of clear airspace in approach, except in caves.

Other swifts depend in intriguing ways upon various bird and plant species. Horus Swifts (*Apus horus*) nest in colonies of bee-

Sitting still on its nest, this Spot-fronted Swift blends remarkably well into its surroundings, despite the highly distinctive white patches on its head; indeed, these too almost appear to imitate the background substrate, as a form of disruptive camouflage. This species typically nests in wet sites close to a waterfall, and, as here, the outside of the nest itself may be permanently wet. Favoured sites are rocky ledges with some protection offered by an overhang. The nest is plastered with mosses and liverworts on the outside, while the inside of the cup itself is normally lined with leaves or fern fronds.

eaters (Meropidae), kingfishers (Alcedinidae) and martins (Hirundinidae), while White-rumped Swifts (*Apus caffer*), and in some areas House Swifts (*Apus nipalensis*), use old nests of Red-rumped Swallows (*Hirundo daurica*). Both New World (*Tachornis*) and Old World (*Cypsiurus*) palm-swifts depend on various palm species. Indeed, the distributions of some of these swifts have increased as the result of an initial range expansion by some of their "host" species. The relationship between the White-rumped Swift and various hirundines is clearly one of antiquity, as Red-breasted Swallows (*Hirundo semirufa*) rarely breed in sites higher than 1 m above ground-level, thus avoiding nest parasitism by the swift; this implies a form of evolutionary "arms race". Perhaps most fascinating of all is the close correlation in the Californian range of Vaux's Swift with that of the Pileated Woodpecker (*Dryocopus pileatus*), the swift nesting in the roosting cavities of the woodpecker. It has even been suggested that Pileated Woodpeckers provide the majority of this swift's nest-sites.

The most typical nest construction is a self-supporting bracket, often attached to a vertical wall. Most swifts use saliva to hold nest materials together and to fix the nest to the substrate. The relatively immense amount of saliva required is produced in the sublingual salivary glands, which are enlarged in the breeding season (see Morphological Aspects).

There are several exceptions to the bracket-shaped nest. The two species of the genus *Panyptila*, the Great Swallow-tailed (*Panyptila sanctihieronymi*) and Lesser Swallow-tailed Swifts (*Panyptila cayennensis*), diverge greatly from this blueprint. Both species incorporate plant down into the nest-wall matrix, using saliva, to produce a material that is typically likened to felt. They make tube-like constructions, that of the larger species measuring up to 66 cm in length, which either hang from their base or are attached along their whole length to a vertical surface.

The three New World palm-swifts, the Antillean Palm-swift (*Tachornis phoenicobia*), Pygmy Swift (*Tachornis furcata*) and Fork-tailed Palm-swift (*Tachornis squamata*), site their nests on the outward-facing surfaces of dried palm fronds. The interior nest-wall is covered in downy seed cases, while the outer wall consists mainly of an untidy covering of loose feathers. The Old World equivalent of these three is the genus *Cypsiurus*, comprising the Asian (*Cypsiurus balasienensis*) and African Palm-swifts. Their nests are similarly, though more openly, constructed and

are typically placed on the upper surface of a palm frond. Both seem more adaptable than their New World cousins, since they have also taken to nesting close to the trunks of some palms, or on thatched roofs and other man-made structures.

The Cypseloidinae, and probably also the needletails, are unusual within the family in not using saliva in nest construction. Four large tropical species do not always build nests, but instead use unlined scrapes in the nest-site substrate. These are the New World White-collared and White-naped Swifts and the Old World Brown-backed (*Hirundapus giganteus*) and White-throated Needletails, and the same probably applies also to the other two, less studied *Hirundapus* species. The New World pair, however, will sometimes make nests, depending upon the circumstances of the site, and it has been suggested that further research into the needletails will reveal similar facultative tendencies.

Saliva reaches its maximum usage in swiftlet nests, and in one species in particular, the Edible-nest Swiftlet, the nest is con-

The Chestnut-collared Swift nests close to water, in shady sites near waterfalls, and sometimes in sea caves. Its nest is a neat cup-shaped structure, built mainly from mosses and liverworts, and attached by its mud base to a rock ledge. The usual clutch is of two eggs, which are incubated for about 25 days. Additional dry plant matter can be added to the lining while the nest is in use.

structured entirely of saliva. The African Palm-swift uses saliva to glue its eggs to the nest, as these are laid in a comparatively exposed position. After laying an egg, with her body pressed firmly against the nest flange, the female slips down over the egg until it is in contact with her breast, at which point she makes a retching action, places her head alongside the egg and applies saliva on the nest next to the egg. A similar process may occur in the Fork-tailed Palm-swift.

An assortment of vegetable matter is used to form the basis of many nests. This is typically collected from airborne detritus and is carried to the nest-site in the bill, though some species have been noted taking material from the outer branches of trees, using their feet. Various cypseloidine species have been observed clinging to water-splashed rock walls and collecting mosses and liverworts for use in nest construction. Nesting materials are frequently stolen from other birds, including other swifts of the same species.

Common Swifts defend their nest-sites, often tenaciously. Potential intruders will call from outside a nesting cavity to ascertain whether or not it is occupied. Entry may induce a conflict, which could carry on for hours and even be fatal. Recent studies into sexual differences in calls indicate that prospecting swifts can glean information regarding not only the occupancy of a nest-site but also whether a pair-bond has been formed, all without entering the nest.

Fighting occurs only after a threat display: one bird approaches the other, both wings raised and one tipped slightly to one side, exposing the strong feet; the relatively feeble bill is used only rarely, and then to little effect. Initial pair reunions invoke threat displays, although mutual preening occurs on reformation. Subsequent returns to the nest by one or other of the pair will elicit a greeting display which is believed to be a mild version of the full threat display. Similar displays are recorded for many other species. In the threat display of the Spot-fronted Swift, both the wings and the body are raised.

Aggression can be aimed at other species competing for the same nest-sites. Common Swifts invariably win these contests when faced with House Sparrows (*Passer domesticus*), though they are less successful against Common Starlings. The most dramatic conflicts involve Alpine Swifts and Feral Pigeons, the domesticated form of the Rock Dove (*Columba livia*). These last two species often breed peaceably alongside each other, but in one instance two adult Alpine Swifts were recorded attacking an airborne pigeon by attaching themselves to it, one on top and one beneath, and flying it directly into a pavement, causing the pigeon serious injury. Aggressive behaviour towards a variety of species has been noted close to colonies: for example, the Plain Swift (*Apus unicorn*) has been observed mobbing Northern House-martins (*Delichon urbica*), and several

Böhm's Spinetail is an Afrotropical swift with very specific habitat requirements, being associated particularly with baobab trees.

The nest seen here was situated in the heart of a large baobab, deep inside a vertical cavity. Access to this cavity was through a hole some 50 cm in diameter at the top of the trunk. The nest was constructed mainly from leaf petioles, and was sited about 5 m below the entrance hole, where it was in near-darkness.

This particular nest site is known to have been used in successive years. *Böhm's Spinetail* has also been recorded as nesting in deep man-made pits.

Several swift species are closely associated with palm trees, most notably those of Old World *Cypsiurus* and New World *Tachornis*, all of which regularly nest in palms. The African Palm-swift normally nests in rather a confined space, but it requires a clear approach route of some 40 m so that it can fly in close to the ground, and then swoop sharply upwards into the leaves. The nest itself, attached vertically to the side of a leaf, is made mainly of feathers, moulded into a small cup to cradle the eggs, which in turn are glued to it using the birds' adhesive saliva.

In the Black-nest Swiftlet, both sexes brood their chick, apparently relieving each other always at night. Sometimes the hatchling is left alone for a while, during which time its temperature naturally drops, but it appears to be adapted to withstand such treatment. The Black-nest Swiftlet is a colonial cave-nester, and is one of several swiftlet species whose nests are collected as a delicacy in Chinese cuisine, an activity with a long tradition, but which is now threatening a number of species. The dark nest of this species has a high proportion of translucent saliva, mixed with feathers, and is one of the nests most sought after by the traders.

individuals of this same swift species combined to chase away a much larger Alpine Swift.

Aerial displays (see General Habits) precede apparent aerial copulation. Some observers are sceptical as to whether this most famous of swift behavioural adaptations does actually occur, and conclusive proof would clearly be very hard to come by. What is thought to be aerial mating has been recorded for a number of species in several genera. In Common Swifts, the female flies in front of the male with her wings held close to the vertical, causing a forward plunge; the male rapidly follows and, as the female levels out into a horizontal flight on quivering wings, he will attempt, often unsuccessfully, to mount her, his wings held high and straight while hers are horizontal, in a shallow gliding descent. More rapid, steeper descents are not uncommon, and this display can occur without apparent mating. One impressive variation on this theme has been recorded for the American White-throated Swift, in which pair-members fly directly towards each other, unite and then "pin-wheel" towards the ground for several seconds.

In South Africa, in late October, M. van Gelder watched two African Palm-swifts tumbling out of the same palm 22 times during 30 minutes, "locked together and spiralling like a winged seed". Although on one occasion he thought that he could see cloacal contact, he was not certain whether this behaviour was copulation or territorial confrontation. Each time, the birds broke from physical contact just above the ground, and then circled back into the palm fronds to start again. A third bird was in close attendance on three occasions, though van Gelder was certain that the tumbling always involved the same two birds. A week later, he noticed that a nest was being built in this particular palm tree. He remarked that, if this had been aggressive territorial behaviour, it seemed strange that the adversaries had co-operated to the extent of not falling to the ground.

Scepticism as to whether these aerial contacts do involve copulation is intensified by the knowledge that the Common Swift is also recorded mating at the nest, as are many other species. Some species, for example many of the swiftlets, are thought to mate only at the nest. M. Marín and F. G. Stiles speculate that

aerial copulation could involve a greater risk of failure, and therefore infertility of eggs, which would certainly be disadvantageous for species which lay small clutches.

Within the apodid family, egg colour is uniform: dull white, seemingly without exception. The eggs of Alexander's Swift (*Apus alexandri*), resident in the Cape Verde Islands, were originally described as white, finely freckled red-brown, but this was apparently based on a misidentification. Swift eggs are relatively small, but have a high yolk content. They vary in size from about 15.5 x 10 mm in the Fork-tailed Palm-swift to 43 x 28.5 mm in the White-collared Swift. Clutch size varies considerably, from a single egg in some swiftlets to seven or more in some *Chaetura* and *Hirundapus* species. The role of both clutch size and egg size is important in responses to unpredictable weather. It has been shown that egg formation in Common Swifts is sensitized to weather-related fluctuations in insect abundance, since females have difficulty in accumulating sufficient energy reserves during poor weather. Larger, older nestlings outcompete younger siblings. Egg size correlates well with nestling survival, as chicks from larger eggs fledge more quickly than those from small eggs, and it has been speculated that size variation in eggs within a clutch is an adaptive strategy serving to optimize sibling competition, facilitating brood reduction in times of inclement weather.

In all species that have been studied in detail, the two sexes share equally in nesting duties. This is presumably another adaptation to the variability of food supply. The inability so far shown by various swift species successfully to raise artificially increased broods shows that nestling survival is finely balanced, and that breeding can place considerable cost upon the adults. According to the model presented by J. Maynard-Smith, such a situation of shared responsibilities evolves when two parents can raise twice as many fledglings as one would have been able to, or when the chance of a deserting parent re-mating is small.

The work of M. J. Tarburton at Chillagoe, in Queensland, revealed a unique incubation strategy. The Australian Swiftlet (*Aerodramus terraereginae*) lays two clutches per season, each of one egg. The second egg is laid 50 days after the first, and is incubated by the developing chick from the first clutch. The

Young swifts hatch naked and in most species they remain so until the flight and contour feathers start to appear, only a very few species growing an interim covering of downy feathers. These Common Swift nestlings are only a day or two old, and their eyes are still closed, but the first signs of the incipient feather tracts are clearly visible on the back of the right-hand chick. The young are fed on a rich diet of insects, which are brought back by the adult in the form of a bolus, and regurgitated directly into the throat of the hungry nestling. If necessary, Common Swift nestlings are able to survive for weeks with very little food, partly by their laying down layers of fat when food is plentiful.

[*Apus apus apus*,

Oxford Scientific Films]

chick's incubating posture is identical to that of the adult and is apparently stimulated by the presence of the egg, although, given the cramped conditions within the nest, there may be little option for alternative behaviour. The nestling incubated the egg throughout the day and probably during the night, despite the adult being present at the nest. The chick's brood patch is also closely similar to that of the parent. There was no significant difference between the incubation periods for the first and second eggs, indicating similar levels of efficiency for the two strategies. In those nests where the first nestling fledged before the second egg hatched, incubation of the latter was completed by the adults. Laying of the second egg, however, is generally timed so that it does not hatch before the first chick fledges. It has been estimated that this strategy saves over three weeks in the total length of the breeding season. Among the intriguing questions raised by this discovery is the possibility, as yet unknown, of hormonal changes in the nestling of the kind associated with incubation in adults. This strategy is considered to be an extreme adaptation to the limited and variable food supply at Chillagoe. All swifts have relatively long nestling periods, again an adaptation to a capricious supply of food. The brooding of the second clutch by the nestling of the first allows swiftlets at Chillagoe nearly to match the annual production of White-rumped Swiftlets (*Aerodramus spodiopygius*) in relatively food-bounteous Fiji.

Large, or rapidly laid, clutches recorded in three *Chaetura* swifts and the White-rumped Swiftlet have been attributed to more than one female laying in the same nest. In one of these species, the Chimney Swift, extra-parental co-operation has long been proven. A third adult, presumed not to be a parent, was observed to be sharing a nest-site and participating in some nestling duties such as feeding, which it performed more frequently than the parents, and brooding. R. W. Dexter's study showed that three adults at a nest was typical, although four were recorded in six out of 22 cases. The additional birds were often first-years, perhaps even the young of the occupying adults from the previous season; in other cases they were very old adults. Helpers were more often males than females. Some of these

scenarios were maintained for more than one season. What seems at first sight an example of apodid altruism is probably a behavioural mechanism benefiting the helper as much as the brood and parents. Helpers are typically first-year birds that would not be able to breed successfully and so do not defend a nest-site; they therefore require a secure roosting site. By undertaking certain nesting responsibilities they are allowed access to a safe roosting environment. As Dexter speculated, some of these visitors are probably just awaiting an opportunity to obtain a mate.

Clutch size in tropical swiftlets has been discussed at length by Tarburton, and it has some general implications for the whole family. Comparison between Australian and White-rumped Swiftlets suggests that food reliability and quantity determine clutch size. In Tarburton's two-year study there were very different levels of rainfall. In the dry year, when there were fewer insects available, the feeding rate was reduced, while in the wet year, with more insects, adults could not supply food successfully to the young of artificially increased clutches. In species that lay more than one clutch in a season, clutch size may vary: for example, Pallid Swifts breeding in Tunisia average 2.89 eggs in the first clutch and 1.95 in the second. Studies of Edible-nest Swiftlets in Malaysia, however, revealed no significant differences between first, second and third clutches.

Swifts are naked when they hatch, most remaining so until their remiges and contour feathers erupt. However, while no swift species has natal down, the members of Cypseloidinae and Apodini show a fluffy nestling plumage of downy semi-plumes. In the case of the African Palm-swift, this adaptation is a result of the exposed nest-site, where the recorded temperature ranges from 15°C to 41°C. The Black and the Chestnut-collared Swifts both choose sites that are cooler and damper than the surrounding habitats, and their young are brooded continuously until the down appears, as with the three *Apus* species.

Weather affects the breeding biology of many swifts. Temperature, sunshine, wind velocity and precipitation all influence

In many areas the Chimney Swift does indeed nest in chimneys, as implied by its common name, but a range of natural sites is also used, including old woodpecker nesting holes. The nest itself is a very flimsy-looking half-cup made from short twigs, firmly cemented together and to the brickwork with adhesive saliva, and normally placed high up in some shady situation.

The normal brood consists of four or five young. Food pellets brought in to the nestlings have been shown to contain over 200 insects each, on average.

The chicks stay in the nest until they are about 30 days old, when they are ready to fly.

Towards the end of their nestling period, the young birds may creep out of the nest and hang tightly on to the nearby walls.

[*Chaetura pelagica*,
Indiana, USA.

Photo: R. Austing/FLPA]

feeding conditions and prey abundance. These factors change throughout the breeding season, affecting laying and hatching dates in the early stages, and nestling growth rates and, ultimately, the timing of fledging in the last phase. At a colony of Common Swifts in Nîmes, in south France, correlation of breeding success with 13 years of meteorological data suggested that rainfall and temperature were less important than north-north-west winds, which had a strong adverse effect on the abundance and ease of capture of prey, and hence on breeding success.

A similar study of Pallid Swifts in north-west Italy indicated that inclement May weather caused females to delay laying until June, although clutch size was not affected by either rain or temperature. The potential length of the breeding season plays a large part, as such a postponement is not an option for the Common Swift nesting farther north. In the latter, up to two days' delay in egg-laying has been noted, and this can be slightly longer if the clutch has not been started. Weather conditions do have some effect on the clutch size of the Common Swift, because in cold seasons two-egg clutches are more successful than those with three eggs. Furthermore, the Pallid Swift's fledging success declines during either very dry or very wet seasons, though the Mediterranean's more equable climate gives that species greater immunity to the weather than the more northerly Common Swift.

The nestling period of Common Swifts averages 42 days, though in poor summers it can extend to 56 days. If the weather is particularly bad towards the end of the breeding season, premature first flights can occur. Australian Swiftlets show the greatest weight gains after periods of rain. Nestling periods across the family are generally long in comparison with those of similar-sized birds, and do not show correlation with size. This long period in the nest is thought to be, in part, a function of the need for full independence after fledging. The longest known nestling period is that of the Spot-fronted Swift, which spends 65-70 days in the nest.

Brood-feeding varies quite considerably, even within a species. A swift brings back to the nest a bolus of insect food, which it then regurgitates directly into the throat of its young. This bolus

may be divided between chicks. It has been observed that, in the Apodidae as a whole, there are significantly more feeding visits per day the shorter the nestling period is.

Many variables affect brood-feeding rate, perhaps most notably the weather. Common Swift nestlings, and to a greater or lesser extent probably all those species breeding in areas where prey abundance varies, can survive long periods, even weeks, with little food. Their weight may drop by half under such conditions. Studies by D. M. Bryant and C. J. Hails showed that those species feeding at the greatest heights, and therefore on the most unpredictable supplies, stored the most fat while in the nest. In many species, a greater number of chicks in the nest stimulates an increase in feeding frequency, while in others the feeding rate varies with nestling age. In White-rumped and Chimney Swifts, feeding visits become more frequent prior to sunset, although the quantity of food decreases.

Experiments in which brood sizes of Common Swifts were manipulated to increase parental effort to different levels showed that, although greater brood size caused the adults to increase their feeding rate, food per chick decreased and both chick weight and parent weight fell. The parents with the largest broods dropped to a dangerously low weight, to which they responded by ceasing to feed their young. In all five nests where the brood was increased to four, and in two out of five where it was increased to three, brood reduction was observed. In these cases, the parents could not successfully raise their larger broods without risking their own survival; their decision to feed only themselves allowed them to survive and feed their remaining nestlings. Again, the tightrope between survival and mortality that results from the nature of the apodid diet is revealed. Although in this case the food-allocation problem resulted from experimental manipulation, swifts must cope with these problems regularly when faced with poor weather.

As previously noted, swift nestlings may be very fat. A high fat level helps them to survive lower feeding rates brought on by inclement weather. This situation, however, produces a physiological dichotomy. As A. Turner puts it, swifts must "juggle the demands of first being fat nestlings and then slim master flyers".

In the last week before fledging, nestlings lose weight to reach the perfect wing-loading and thereby effect a 10% increase in flight efficiency, with subsequent energy reductions and manoeuvrability enhancements.

The young of several species have been noted performing a variety of wing exercises before leaving the nest. In Böhm's Spinetail, which is recorded nesting in deep man-made pits, young birds have been seen clambering up the wall close to their nest, rapidly beating their wings, with frequent resting periods during which they supported themselves by using the tail. Another type of exercise is akin to human press-ups, with the body raised from the floor by outstretched and downward-inclined wings; at first, nestlings can hold this position only briefly, but as they grow they are able to prolong it, and it has been speculated that this may indicate readiness to leave the nest. Young African Palm-swifts are particularly precocious. They are restless within hours of hatching, and as early as the fourth day they climb away from the egg chamber onto the supporting flange, and from there up above the nest onto the palm frond.

Swift nests are kept clean by the combined efforts of parents and nestlings. Young White-rumped Swiftlets defecate over the rim of the nest from the first day of hatching, and the chicks of other species behave in a similar way, though not necessarily from such a young age. In the case of very young Chimney Swifts, the adults either remove the faeces from the nest or ingest them. Nests of Common Swifts become more soiled as the season progresses, as old faeces are not removed from the nest and eventually even fresh ones are ignored with greater regularity. Eggshells and dead eggs are typically ejected from the nest, although not apparently in the case of the three swiftlets in the study at Niah, in Sarawak. African Palm-swifts crush the shell into tiny pieces, which then fall from the nest.

Nest parasites are a feature of all swift species. Studies of White-rumped Swiftlets in Fiji revealed that louse fly (*Myophthiria fijiarum*) infestation was related to nesting density, chicks in the most isolated nests being free of the flies while the greatest fly numbers occurred where nests were touching. However, such ectoparasites may cause very little harm to their hosts. An ingenious experiment in England, at Oxford University, in which populations of the flightless louse fly (*Crataerina pallida*) and the

chewing louse (*Dennyus hirundis*) were artificially altered to produce a bimodal loading, showed that reproductive success and individual survival rates were independent of the level of ectoparasites. This is believed to be due to the fact that these parasites colonize new hosts by infecting offspring of adults (vertical transmission), so that any harmful impact upon the host will affect the survival of the parasite, too, by reducing the number of hosts available. However, particularly heavy infestations of biting lice can imperil swifts, especially if they are physiologically stressed, such as in the case of exhausted individuals on migration.

A number of predators will take both adult and nestling swifts. Young Atiu Swiftlets are sometimes killed by crabs, which even apparently knock the nests off the walls on some occasions. Various predators, ranging from African Red-winged Starlings (*Onychognathus morio*) to Spotted Eagle-owls (*Bubo africanus*), have been known to prey on the eggs or nestlings of the African Palm-swift.

Fledging success within the family varies from 26% in the latter species, with its comparatively vulnerable nest-site, to 96.1% in the Chimney Swift. Overall breeding success for African Palm-swifts is, however, only 17%, the same as for Black-nest Swiftlets, which produced only 0.2 young per breeding effort at Niah, a testament to the disruptive nature of nest-harvesting (see Relationship with Man). The effect of the weather upon nesting success of temperate-breeding species seems to vary, studies of Chimney Swifts suggesting that nestling survival relies less on suitable weather conditions than is the case with the Common Swift. It is interesting to speculate on what role helpers have to play in this reduced intimacy with climatic conditions, although the breeding success of the Chimney Swift does not seem to vary with the presence or otherwise of these helpers.

Swifts are long-lived birds with low mortality rates. The oldest ringed Alpine Swift was 26 years of age, while Common Swifts of 21 years and Chimney Swifts of 14 years have been recorded. As in many other families, mortality is much higher in the first year. On Gibraltar, a colony of Pallid Swifts showed a first-year mortality rate of 67.3%, compared with a subsequent annual rate of 26%. For Common, Chimney and Chestnut-collared Swifts, annual survival rates of, respectively, 81-85%, 83-85% and 71-81% have been recorded.

Alpine Swifts have adopted man-made nest sites to a much lesser extent than Common Swifts (*Apus apus*). Their natural nest-sites are mountain ledges, coastal cliffs and caves, but they do regularly nest on buildings in southern European towns and cities, as here in Italy on a wooden beam in the roof of a school building. Indeed, some cities, notably Istanbul, have very large urban populations of Alpine Swifts. Like most of the members of Apodidae, the Alpine Swift is a long-lived species, the oldest recorded bird having reached an age of 26 years.

When threatened on the nest, a young swift will often raise its wings in an aggressive display, as demonstrated by this Black Swift. Young swifts are raised on a very rich diet of insects, which promote rapid growth. The frequency of feeding depends very much on the success of foraging, and thus on the weather.

The nestlings of some species are, if necessary, able to survive for weeks with very little food, largely due to their tendency to lay down layers of fat during periods when food is plentiful: during spells of bad weather the birds draw on these reserves in order to maintain their rhythms of growth. One direct consequence of this strategy is that in normal conditions the chicks grow decidedly fat, which in time would clearly be a distinct disadvantage for the day when they launch themselves into mid-air and embark on a highly aerial way of life. In order to meet this problem, over the last week or so of the nestling period they start to lose weight. During this same period, the birds perform a series of wing exercises in order to bring themselves into trim. One of the most remarkable of these involves a form of press-up, in which the bird stretches out its wings and tries to lift its body off the ground!

Movements

The extreme seasonal variability of insect abundance in the temperate zone forces long-distance migration on the majority of those species breeding outside the tropics. Within the tropics, post-breeding dispersal and altitudinal and pursuing movements are commonplace, while diurnal foraging movements on a variety of scales are a feature of this family. All species usually migrate in flocks, which may be small or large. Migration can be very rapid: one Common Swift is known to have migrated 1275 km in four days, while the larger and even faster Alpine Swift was proved on one occasion to have moved 1620 km in three days.

Some migration occurs at night. At Fraser's Hill, in Malaysia, several migrant species of swift have been captured after being attracted to bright security floodlights. Migration occurs on a broad front, with little funnelling at narrow sea-crossings. Indeed, it is believed that Black Swifts that have bred in North America may migrate from Central America into South America over the eastern Pacific, basically cutting the corner, and Chimney Swifts leaving eastern North America pass regularly over the Caribbean, earning their specific name *pelagica*. Migration often takes place at high altitude, and becomes apparent only when poor weather forces flocks down.

Long-distance movements by temperate-breeding species are not confined to annual migrations. Swifts will undertake major

An unusual sight in modern times is to see Common Swifts using a "natural" nest-site, for instance, as here, a hollow in a broken tree. The extraordinary success of this species in adapting its nesting habits in order to make use of man's buildings has led to its nesting almost exclusively in man-made sites nowadays. In some areas, humans have even taken more active steps to help the local swift populations by setting up specially designed nestboxes; these tend to be rather narrow and also prove attractive to bats.

[*Apus apus apus*, Sweden.

Ardea]

movements to escape adverse weather at any time of the year, and these occur on a number of scales. For instance, Common Swifts fly ahead of storm fronts before they cross them, returning to their breeding grounds in the relatively clement weather behind the front. It has also been noted that swifts take advantage of the relative abundance of aerial plankton in these situations, caused by updraught associated with convection. Escaping from low-pressure systems can take much longer, not least because swifts can react to an oncoming cold front that is still 500 km away. These movements are presumed to be triggered by various meteorological factors which in turn bring about a reduction in food supply. The birds fly into the wind, hence in the Northern Hemisphere circling in a clockwise fashion, usually into the warmer areas south or south-west of the depression. One of the most celebrated examples of such food-driven nomadism comes, again, from the Common Swift, whose mass movements around depressions in the breeding season to avoid rain can entail round trips of up to 2000 km. Tens of thousands of Common Swifts can be involved in a single group, leaving the breeding grounds for days or even weeks, and birds from southern England have been known to feed as far afield as Germany at such times; many of these individuals will be non-breeders, but parents are often involved, utilizing their fledglings' ability to survive long periods without food (see Breeding). Black Swifts in North America are known to undertake similar flights, which may be common throughout the family, particularly among those species that occur in temperate climates.

Various strictly tropical species also undertake annual migrations, as well as more nomadic wanderings. The White-collared Swift and some African species have been noted making pursuing movements, taking advantage of the abundance of insects disturbed by savanna fires during the dry season. For Common Swifts, at least, arrival on the sub-Saharan wintering grounds does not signal the end of their travels: complex intra-African migrations, often involving escape movements, take place throughout the winter.

Diurnal movements to suitable foraging habitat are typically much shorter, and often involve a daily flight from a roosting or nesting site lacking adequate food supplies, or perhaps to a particular site with an abundance of food. This phenomenon is readily seen in the area around the Rift Valley lake of Naivasha, in

Kenya. During the day, huge numbers of Nyanza Swifts (*Apus niansae*) and lesser numbers of Mottled Swifts feed over the lake, where there is an abundance of insect prey; in the evening, they return in their tens of thousands to the nearby, though relatively arid, savanna-filled Hell's Gate Gorge to roost. Similarly, many swiftlets breeding on offshore islets undertake daily journeys over the seas to suitable feeding habitat.

As with so many aspects of behaviour in this family, the timing of migration can be greatly affected by the impact of climatic vagaries upon the aerial plankton which forms the diet of all swift species. The most striking example came from Finland in the autumn of 1986. Most of the Common Swifts had left as usual by late August, but as many as 2000 adults apparently "returned" in mid-September; they commenced the moult that they usually undergo on their wintering grounds and eventually died, either from starvation or as a result of the November frosts. It is thought that the unusually bad weather in the autumn of that year prevented the birds from accumulating sufficient fat deposits for them to undertake their long southward migration. Another case of mass mortality was recorded on the small and remote Islas del Cisne (Swan Islands) in the Caribbean, 180 km off Honduras, when a flock of some 200-300 Chimney Swifts died over the course of a week in October. The low level of insect life on the islands was indicated by the emaciated state of the birds collected.

The extreme mobility of swifts has assisted their colonization of the globe. Even many of the comparatively sedentary swiftlets inhabit oceanic islands that have never formed part of any continental landmass, while the family enjoys a near-cosmopolitan distribution. It is fair to state that, with the exception of some island groups, every site that can support some species of swift does so. The near-ubiquity of the Apodidae stands testament to avian dispersive power. Vagrancy is the most obvious manifestation of this attribute, and it is perhaps our only means of observing fluctuating distributions, and changing migratory pathways, in the geological instant that is our lifetime.

Sometimes, these episodes of vagrancy will lead to colonization, perhaps even rapid colonization, of a new area, if conditions are right, as can be seen in the case of the White-rumped Swift in Spain, the Pallid Swift in southern Europe, and the African Palm-swift in southern Africa. On other occasions, the arrival of an individual thousands of kilometres away from its typical

areas of occurrence will tempt observers to form elaborate theories that fit only a regional view of the issue.

In short, the poorly termed phenomenon of vagrancy is nothing more than individual variation in migratory behaviour, writ large. It acts, unconsciously, as a mechanism that allows for range expansion. The global environment is not renowned for periods of equilibrium, and on a superficial level one might say that any species attempting to hold back the inevitability of extinction will respond to this environmental change, or that a species that sits still will hasten its own demise. The work of P. Berthold and others has proved the high heritability of migratory-goal direction, and this may help to explain patterns of vagrancy. Those individuals that take the opportunity to sample life away from the strongholds of their species are very likely to produce no offspring, but they may presumably gain temporarily from a lack of competition for resources. If they survive long enough to breed, the chances of their offspring undertaking a similar journey will be higher than if these had had different parents.

The history of, for example, the Plain Swift, which breeds primarily in the Canaries and Madeira, would seem to be similar to that which has been proposed for the Hawaiian Goose (*Branta sandvicensis*). Common Swifts and their recent ancestors must have strayed to the Canaries on countless occasions throughout the Quaternary, as they do regularly to this day. The evolution of the Plain Swift is proof that some did, indeed, stay long enough to breed in the hospitable climate of those islands. Subsequent natural selection in isolation, no doubt exacerbated by the founder effect, accounts for the morphological differences between the two species. Interestingly, Common Swifts are now believed to be nesting on Gran Canaria, where a few have been present during the breeding season in recent years.

Spectacular cases of vagrancy have been recorded for a number of species. Trans-Atlantic vagrancy is well established among swifts and, unlike in most other landbirds, has involved westward as well as eastward movements. Alpine Swifts have been recorded in the Caribbean on at least three occasions, while there have been several Chimney Swifts in Europe, as well as records from Greenland and Tenerife. White-throated Needletails have been found in Europe on more than a dozen occasions, as well as in the Aleutians and the Seychelles. The latter archipelago has in fact been visited by several continental swift species. Common Swifts have reached

the Pribilof Islands, off Alaska, and many oceanic archipelagos, including the sub-Antarctic Prince Edward Islands. Pacific Swifts (*Apus pacificus*) from eastern Asia have occurred at least ten times in Alaska and, more remarkably, twice in Britain. The western North American Vaux's Swift has strayed on a number of occasions to the eastern seaboard, the Ashy-tailed Swift (*Chaetura andrei*) has been recorded on the remote Falkland Islands, and a Black Swift, probably of Caribbean origin, strayed as far north in the USA as Martha's Vineyard, in Massachusetts. Other notable incidents of overshooting have been recorded for the southern Mediterranean White-rumped Swift, which has occurred in Scandinavia, while Alpine Swifts are annual vagrants to the British Isles. Seemingly sedentary, island-bound species are also capable of the odd surprise, Antillean Palm-swifts having been found in the Florida Keys and on Puerto Rico.

Relationship with Man

Few families have such an ambiguous relationship with man as the Apodidae. On the negative side, human destruction of habitat has greatly diminished foraging areas for some species, while over-harvesting in the lucrative bird-nest trade is taking its toll on South-east Asian swiftlet populations, and insecticides and herbicides have severely reduced both the range and the number of insect prey in many areas. At the same time, many species have found ready-made nest-sites in buildings or benefited from the spread of palm trees, essential as nesting sites for some swifts.

Many species have taken advantage of artificial sites, and some no longer use traditional sites to any extent. For example, in a report of a Chimney Swift nesting in a hollow silver maple (*Acer saccharinum*), the observers noted that fewer than ten incidents of tree-nesting had been recorded in the previous 100 years. The use of buildings has not only improved nesting success, perhaps as a result of nest-site security, but has also facilitated range expansions in several species.

The extent of this evolutionary opportunism and the near-total conversion of many species to artificial nest-sites are leading to problems closely akin to those experienced by many bat species. In the case of the Common Swift, roofing repairs are seldom undertaken with the welfare of the birds in mind. Ex-

The Alpine Swift is one of the great migrants among the Apodidae, its breeding grounds stretching north into southern Europe and up to Central Asia, with most birds wintering in tropical Africa. It tends to migrate at high altitude, and it is frequently the case that its movements are observed only when wet weather or wind forces the birds down. Even on a local scale, its mobility is notable, and birds regularly cover long distances, estimated at perhaps 1000 km each day. One migrating Alpine Swift was recorded as covering 1640 km in a matter of only three days.

tending roofing felt, inserting concrete fillets under tiles, and putting anti-insect meshing into air-bricks may benefit the human inhabitants, but such actions have contributed in many parts of Europe to a decline in swift populations.

A British Trust for Ornithology initiative, "Concern for Swifts", has highlighted the dilemma, and as a result some local council authorities have introduced "swift-friendly" measures such as incorporating swift boxes into eaves. In some places, such as Amsterdam, in the Netherlands, it has long been an offence to obstruct the nest entrances of swifts. However, such measures, though welcome indeed, are unlikely to reverse the downward trend unless legislation, preferably at a supranational level, is introduced.

It is doubtful that any wild birds are so financially important as the swiftlet species that produce the so-called edible nests. These nests, composed primarily or, in the case of the aptly named Edible-nest Swiftlet, entirely of saliva, have long been considered a delicacy in Chinese cuisine and form the main ingredient of the famous bird's-nest soup. This trade in nests dates back at least to the late Ming and early Ching dynasties of seventeenth-century China. Some claim a far longer history and believe that these nests may have been consumed in China as long ago as AD 500, while there is some evidence that trade with Sarawak may go back to the year AD 700. It is apparent, however, that in recent decades the populations of these birds have not managed to match the insatiable demands of this multi-million-dollar industry.

Over-harvesting and destructive harvesting have long been problems. Estimates from Gomantong Caves, in Sabah, during the 1959 collecting season suggested that 190,000 eggs and nestlings were destroyed as harvesters simply threw them from the nest to the cave floor. Insensitive practices have caused a decline in the famous Niah Cave colonies of Sarawak, which at one time were thought to number 4,500,000 birds; estimates from the late 1980's and early 1990's put the Niah population of Black-nest Swiftlets at somewhere between 150,000 and 298,000 birds. As might be expected, falling swiftlet populations have reduced the annual nest harvests. Yet there is little wonder that the trade is perpetuated, as the export value of this commodity to the Sarawak economy was US\$10,400,000 in 1995, with some owners of the customary rights for Niah earning up to US\$20,000 per annum solely from this source. The main producer, Indonesia, is thought to export nests worth as much as US\$1,060,000,000 per annum.

On a global scale, in 1989, a total of 19,900,000 swiftlet nests was traded across state boundaries, and that in addition to those nests used in the countries of origin. The vast majority of this trade is centred upon Hong Kong. A staggering 18,700,000 and 17,500,000 nests were imported into Hong Kong in 1990 and 1991, respectively, with a relatively small proportion being sold to other countries; indeed, in 1989, as many as 25,000,000 nests were consumed in Hong Kong alone. The cost of these nests is truly astronomical. In the early 1990's, good-quality nests could fetch over US\$1225 per kilogram, although figures of US\$367-611 were more typical. During the 1980's, between 81,000 and 160,000 kg of nests imported into Hong Kong had a value of between US\$5,000,000 and US\$39,000,000. Astonishingly, it is now thought that prices could be as high as US\$36,000 per kilogram. To put this into perspective, between 80 and 120 nests make up 1 kg and it is thought that Indonesia alone may harvest 200 tonnes annually, which would represent at least 16,000,000 nests. Not surprisingly, such exploitation of nests has had a severe impact on the populations of a number of swiftlet species (see Status and Conservation).

With such huge figures involved, it is equally predictable that "dirty business" surrounds some of the operations. In 1998, the *Bangkok Post* denounced the enormous sums being made by the concessionaires and also the Thai government department that issues the concessions, while no benefits whatsoever passed to the local human populations. Indeed, the locals are actually banned even from landing on such islands, a prohibition which, it is claimed, is sometimes enforced even by means of "legalized murders" that are subsequently passed off as self-defence. As if this were not enough, in 1996 the largest concessionaire declared exports of 700 kg, whereas the records

The Brown-backed Needletail breeds in the Indian Subcontinent, Sri Lanka and the Greater Sundas. It is a partial migrant, some of its populations or individuals making regular movements, while others essentially stay put all year round. It is a very large swift with a bulky body, a protruding head and prominent tail spines; the characteristic white undertail-coverts and flanks are clearly visible in flight.

[*Hirundapus giganteus indicus*,
Khao Yai National Park,
Thailand.
Photo: Morten Strange]

of the Customs Department showed that the overall figure for this company, together with its smaller competitors, was way up at 9000 kg! Collectors apparently harvest the nests twice during the season, so that the swiftlets are forced to build three nests if they are to have any hope of breeding, while another consequence is that their salivary glands are so exhausted that the third nest is often stuck together with blood and other materials too. Despite legal protection and purported control of the trade, it seems difficult to imagine that the swiftlets can sustain such an onslaught indefinitely.

The swiftlets' much-sought saliva may turn out to have other uses for humans too. It has recently been suggested that one particular water-soluble glycoprotein found in this saliva may prove to be a useful adjunct to existing drugs used in combating immunodeficiency in AIDS, as it is thought to promote cell division in the immune system.

Finally, turning to quite a different matter, it is hard to estimate the beneficial effects of swifts, or indeed of any insectivorous species. Their readiness to take advantage of short-term concentrations of food indicates their special potential as natural pest-controllers. Large numbers of Little Swifts and Asian Palm-swifts have been observed feeding on certain insect pest species during infestations in southern India, but dusting of the areas over which these swifts were voraciously feeding with a cocktail of pesticides caused a massive reduction in the frequency of foraging. Studies of House Swifts in Yunnan showed that 67.5% of all insects eaten by this species were agricultural pests, while only 13% were beneficial, and studies of Pacific Swifts in China have yielded similar results.

Status and Conservation

Six species of swift are currently considered threatened, but differing taxonomic views swell this figure to eight, while another three taxa are listed as Near-threatened and three more as Data-deficient. Although as many as five of these 14 swift taxa are not given full specific recognition by all authorities, this should not in any way reduce the importance of the case for the conservation of each. Management programmes for their protection are typically hindered by lack of detailed biological data.

Of the six species classified as Vulnerable, the White-chested Swift (*Cypseloides lemosi*) was described as recently as 1962, when it was observed in the field and collected in the Upper Cauca Valley of south-west Colombia. Recent sightings in north-central Colombia, as well as farther south in north-east Ecuador and north-west Peru, suggest, however, that its distribution may prove to be more extensive than was previously thought. The species' ecological requirements are unknown, although it has been noted foraging over eroded grassy hills with scattered scrub. This habi-

tat is believed to be increasing in area, perhaps as a result of deforestation in the region.

The Seychelles Swiftlet (*Aerodramus elaphrus*) is threatened not only by the lack of sites, but also by an unfortunate cocktail of problems: predation by introduced species, especially cats, and Common Barn-owls (*Tyto alba*), as well as human disturbance, both accidental and deliberate. Although only six colonies are known, it is considered likely that undiscovered colonies exist and the total population, based on 1996 and 1997 figures, is thought to number roughly 2500-3000 birds, with about 2263 individuals on Mahé (including some 500-600 at La Gogue), about 79 pairs on Praslin and 35-45 pairs on La Digue. A recent increase on the last of these may be the result of changed hydrological conditions or of immigration from Felicite, where a colony has disappeared.

Confined to the Philippines, Whitehead's Swiftlet (*Aerodramus whiteheadi*) is a Vulnerable species whose true rarity was clouded for many years owing to the misallocation of other taxa within this species. It is known only from Mount Data, on Luzon, where four specimens were taken in 1899, and Mount Apo, on Mindanao, where three specimens were collected in 1904. After an absence of some 90 years, a series was recently collected from South Cotabato, on the latter island. This species is believed to be threatened by habitat loss.

The Atiu Swiftlet, which may yet prove to be a race of the White-rumped Swiftlet, was discovered in 1973, when the single known cave, on Atiu Island in the Cook Archipelago, contained 60 nests. A census in 1987/88 revealed a total of 190 nests in two caves. Although the swiftlet's numbers are believed to be stable, disturbance by tourists, even on such a remote island, may present a problem.

Schouteden's Swift (*Schoutedenapus schoutedeni*), known from only five specimens, is one of several rare species inhabiting the Itombwe Forest area of eastern Zaire, and it too is listed as Vulnerable. It has not been recorded since 1959, and the difficulties of field identification suggest that further information would need to be gleaned by trapping. As so little is known of its sole congener, the comparatively abundant, though confusingly named, Scarce Swift, it seems likely that, if Schouteden's Swift does still exist, it may be many years before it surrenders its secrets.

The Dark-rumped Swift (*Apus acuticauda*), also listed as Vulnerable, was first collected in Nepal, although there is some speculation that the specimen may actually have come from India. It is known with certainty to breed only in the Khasi Hills of Meghalaya, north-east India. In the past, at least, it appears also to have bred in Assam, on the strength of a series of specimens collected in the Lushai Hills; these birds were apparently breeding at a different time of year from those in the Khasi Hills, on

A Common Swift returns to its nest on the 16th floor of a modern building in Milan. In this case the swifts are making use of the narrow air-conditioning vents set into the brickwork. These offer a safe, inaccessible site for their nests, and in many respects might be considered structurally similar to part of a natural cliff. From here the birds make regular flights in the surrounding airspace, searching for flying insects; this bird is returning with its crop full of food for the young.

[*Apus apus apus*, Milan, Italy.

Photo: Paolo Fioratti/Oxford Scientific Films]

the basis of the different timing of moult. The species was recently recorded in Bhutan, in the springs of 1996 and 1997, and it is still occasionally reported from Thailand in the winter. The lack of biological study of this species, however, gives little indication as to how stable this small population may be.

Another South American *Cypseloides* species, the indistinct Rothschild's Swift (*Cypseloides rothschildi*) of north-western Argentina and perhaps elsewhere, is listed as Near-threatened, although very little is known of any aspect of its ecology or current status, and even its distribution remains most inconclusively defined. This is due in no small part to the great difficulty of identifying it in the field.

The Waterfall Swift is another Near-threatened species. It is restricted to the Sundaic region, where it is known from a small number of sites. Its stronghold is the Cibereum Waterfall in the Gunung-Gede/Pangrango National Park, in western Java, where 60-80 birds were recorded in August 1985; the species is also regularly seen at the Letter W waterfall near Gunung Kerinci, in Sumatra, with up to eight seen in 1991. It may prove to be more widespread in Sumatra: as well as more historical records, a group of eight was recorded at Gunung Leuser in the north in July 1986, with seven during October, and two were seen at Brestagi in February 1994. In addition to historical Bornean specimens, this species has been recorded in recent years from the Mount Kinabalu National Park, in Sabah.

Like the Seychelles Swiftlet, the other island swiftlet of the Indian Ocean, the Mascarene Swiftlet (*Aerodramus francicus*), is also rare, but it is currently classified as Near-threatened. While seemingly restricted by a lack of suitable breeding sites, it is actually relatively abundant within its small range, although a number of colonies on Reunion are threatened by the activities of speleologists.

One of the most contentious taxonomic cases is that of the White-fronted Swift (*Cypseloides storeri*), currently listed as Data-deficient, from the sierras of south-west Mexico. Since its description as a new species in 1992, based on a bird collected from the tent of the describing scientists, and the subsequent discovery of further specimens in museums and a mummified individual collected from a dried stream bed, there has been much debate as to this form's relationships and even its migratory status. One of the major players in this debate has recently documented a probable field sighting of this swift. Even if it does prove to be a race of the White-chinned Swift, or merely just a geographically isolated population, its apparent rarity in this region still justifies further study.

The Data-deficient Mayr's Swiftlet (*Aerodramus orientalis*) is another enigmatic species, known from only three specimens. These were collected from such widely separated island locations as New Ireland in the Bismarck Archipelago in 1935, Bougainville in the western Solomon Islands in 1979, and Guadalcanal in the eastern Solomons in 1962. The lack of any additional data makes it difficult to know whether this geographical pattern indicates a mere relict of a much wider range or whether the species might be found on intervening islands. Interestingly, in July 1987, a large unidentified swiftlet was recorded on New Georgia in the central Solomons, and small numbers of a large swiftlet thought to be Mayr's were recorded in mid-May 1989 on Manus, in the Admiralty Islands (western Bismarck Archipelago).

Of the forms listed as threatened but not herein considered full species, the race *vulcanorum* of the widespread Himalayan Swiftlet (*Aerodramus brevirostris*), commonly known as the Volcano Swiftlet, is considered Vulnerable. Historically it was confined to volcanic peaks in Java, but all recent records are from a single locality, Gunung Gede. The restricted nature of its habitat requirements and its limited distribution imply that it has never been truly common. Its predilection for nesting within the craters of active volcanoes ensures that periodic extinction is the fate of many colonies.

The Tahiti Swiftlet, the nominate race of the Polynesian Swiftlet (*Aerodramus leucophaeus*), is restricted to Moorea, where it may be only a vagrant, and Tahiti. It too is classed as a Vulnerable form, one which formerly occurred also on Huahine Island, and which has declined throughout the twentieth century. It is believed that the loss of both chicks and eggs to the introduced Common Myna (*Acridotheres tristis*) may be a sig-

nificant contributory factor in this decline. In 1984, an estimate of only 200-500 individuals was made, and a survey between 1986 and 1991 located this swiftlet in only six out of 39 suitable valleys on Tahiti.

The Bioko Swift, the race *sladeniae* of the African Swift (*Apus barbatus*), is classed as Data-deficient and, like some of the preceding species, is known from only a handful of specimens. It has been collected from a wide area: the Obudu Plateau in south-east Nigeria, Mount Kupé in western Cameroon, the island of Bioko (Fernando Póo), and Mount Moco in Angola. Six of the ten specimens are from Bioko, where they were collected in December 1903 and early January 1904, and it has been suggested that this form may be only a vagrant to the island from which it was named, rather than a resident. It may also occur in Liberia. The scarcity of field sightings, coupled with the taxonomic uncertainty of this swift, justifies its categorization.

Other, less threatened species are afforded protection by various national laws, and in some cases by international treaties. Within Europe, the Plain Swift is designated a Species of European Conservation Concern, Category 4, since over 50% of its population is found within the European Community. The Pallid and Alpine Swifts are given Provisional threat status. The Guam Swiftlet (*Aerodramus bartschi*) is protected by the US Federal Endangered Species list 1984. The recent decline in the Sri Lankan population of the Indian Swiftlet, despite strong laws with severe, though welcome, consequences (see below), is a salutary reminder that legislation alone will not be enough to protect any species, let alone the rarer ones.

The collecting of and trade in nests of swiftlets (see Relationship with Man) has led to serious concerns for the future of some species, at least locally. In response to the dwindling populations at Niah, a complete ban on harvesting was imposed between 1989 and 1991, with a further four-year extension from 1993. Despite this, the downturn in numbers continued, due in no small part to considerable poaching. It goes without saying that, if such high-profile sites cannot be adequately protected, then smaller sites, with no monitoring, must suffer enormously. Indeed, along the Andaman coast of Thailand, poaching is rife on the myriad small limestone islands honeycombed with suitable caves for nest-sites. Many of the islands are leased to collectors, and in the early 1990's one businessman paid US\$1,500,000 for the rights to collect on approximately 60 islands. The conflict between the authorized collectors and the poachers may have considerable human cost, too, with many reports of shoot-outs between the adversaries, not to mention the danger of climbing to the roof of massive caverns, supported only by bamboo structures.

A decline in the population of Edible-nest Swiftlets has occurred on the Nicobars since the Indian government began settling people on these islands in the late 1960's. Traditional "swiftlet-friendly" harvesting practices have been replaced, and further problems have been caused by the activities of poachers from Thailand. In addition, those caves that have witnessed declines in this species have seen increases in Glossy Swiftlets and a bat species. R. Sankaran believes that inclusion in Appendix I or at least Appendix II of the Convention on the International Trade in Endangered Species (CITES) would be helpful, but notes that "protection alone may not help populations to recover because an increase in numbers will be possible only if the Edible-nest Swiftlets outcompete the other two and regain nesting space".

National protection in Sri Lanka, where Indian Swiftlets have been protected by law since 1963, with an amendment made in 1993 increasing the penalties for disturbance, has not stemmed the illegal trade that resumed as recently as 1993, despite a record fine of US\$370,000 in 1995. This fine resulted from the seizure of nests weighing 44 kg, bound for the Far East.

None of the swiftlet species producing edible nests has protection under international law. In November 1994, at the Ninth Conference of Parties signed up to CITES, Italy proposed that all of these species should be placed on Appendix II, but this was later withdrawn. Despite the gloomy scenario so far depicted, it seems that there may, ultimately, be some hope. So-called swift houses, purpose-built structures for swiftlets to nest in, have been developed in Indonesia and used with great effect. The struc-

The Seychelles Swiftlet is restricted to the islands of Mahé, La Digue and Praslin in its namesake island group, where it nests in caves. The total population is believed to be of the order of 2500-3000 birds, and like some other rare Seychelles birds it is threatened by the introduction by alien predators, notably cats and Common Barn-owls (*Tyto alba*). The Seychelles Swiftlet forages widely over the forests and wetlands in search of insects.

tures are first occupied by Glossy Swiftlets, which act as surrogate parents to the eggs of Edible-nest Swiftlets which are placed inside. The hatchlings of the latter species return as adults to the artificial structures and establish colonies.

Beyond the bird's-nest trade, swifts are not otherwise commonly the target of deliberate human interference unless they occur in densities that allow for easy capture. There is a record of a swift being killed with a bow and arrow in Zaire, and in Thailand swiftlets have been picked out as targets by catapult-users. Such opportunistic human predation probably has little impact upon swift populations. In the Philippines, however, large numbers of Purple Needletails are apparently killed on occasions when feeding around bee hives, and Common Swifts in Malawi are netted and eaten. Similarly, the huge flocks of Scarce Swifts that sometimes feed low over the ground are exploited as a food source by people using nets, and are even killed by being struck with sticks. In some Liberian villages, thatched constructions 3-5 m high are provided for the use of African Palm-swifts, at least in part to enable the villagers to take and eat the young. In Spain, a technique for catching swifts for food involved flying a kite trailing a hook baited with grass, which the swifts took for nesting material, facilitating their capture.

Accidental death resulting from human activities is more frequent. Swifts sometimes collide with man-made obstructions such as telephone wires. There is also an example of a Great Dusky Swift (*Cypseloides senex*) hitting a plane, a hazard which has also proved fatal for aerial-roosting Common Swifts. A worrying case from Africa concerns African Palm-swifts dying after drinking chlorinated water from a swimming pool. How many other birds die in this way? Species that nest and roost in chimney sites often suffer from burning and asphyxiation. Members of a small colony of Short-tailed Swifts breeding in one Bolivian chimney fell into the fireplace on a number of occasions.

More disturbingly, there is some evidence that swifts are the recipients of dangerous levels of pesticides, in much the same way as are various raptors. On the Pacific island of Guam, the endemic Guam Swiftlet has been recorded with body-tissue concentrations of DDE averaging 0.27 ppm. The notorious pesticide DDT is soluble in body fat and forms the highly stable compound DDE. This pesticide is one of several that have been proved to reduce breeding success in a number of birds of prey. When one considers the relative position of swifts in the food chain, and their longevity, it stands to reason that pesticides pose a risk to this family.

Several forest species show signs of contracting ranges. In some instances, they can no doubt feed with similar success over second-growth as opposed to primary forest, but the removal of mature trees with suitable niches for nesting has presumably affected many forest species. The importance of such mature trees is illustrated by the case of African Swifts, which will continue to use large trees for nesting and roosting despite the clearance of other trees around them. It has even been postulated that the complete removal of old growth from forest in parts of western North America may lead to the regional extirpation of Vaux's Swift.

Most controversial is the effect of potential human-induced climate change on swift populations. The role of temperature and precipitation in providing suitable breeding conditions, primarily an adequate arthropod food supply, is undeniable. If current models of climate change are to be believed, a global change in climate would undoubtedly have a profound effect upon these birds. Observers looking for evidence of global warming could point to the spread of such traditionally tropical species as the House Swift, the Little Swift and the White-rumped Swift into relatively northern, and indeed also southerly, climes. Such biogeographical evidence, however, suffers from the same deficiencies as the meteorological evidence. Our database covers but a brief instant of geological time. Intuitively, we believe that human activities must affect the climate and the patterns of avian distribution, but have the ranges and populations of swifts, seemingly climatic litmus papers, waxed and waned throughout the Quaternary?

Subfamily CYPSELOIDINAE

Genus *CYPSELOIDES* Streubel, 1848

1. Chestnut-collared Swift

Cypseloides rutilus

French: Martinet à collier roux German: Rothalssegler Spanish: Vencejo Cuellirrojo

Taxonomy. *Hirundo rutila* Vieillot, 1817, Guyana.

Forms superspecies with *C. phelpsi*. It has recently been suggested that present species, probably along with less studied *C. phelpsi*, be included in *Streptoprocne* due to similarities in clutch size, development of young, and plumage, and these details would certainly suggest a close link with that genus: species formerly placed in *Chaetura*. Race *brunnitorques* rather similar to nominate, and may be synonymous. "*Chaetura nubicola*" is synonym of present species. Three subspecies currently recognized.

Subspecies and Distribution.

C. r. griseifrons (Nelson, 1900) - W Mexico.

C. r. brunnitorques (Lafresnaye, 1844) - SE Mexico to Bolivia.

C. r. rutilus (Vieillot, 1817) - Venezuela to Guyana and Trinidad.

Descriptive notes. 13 cm; 21 g. A medium-sized swift with a broad, shallowly forked tail and rather broad wings; blackish plumage, slightly paler below; most apparent features are dull red throat and collar; some brown feathers admixed on ear-coverts and on centre of throat. Female has shallower tail-fork on average than male, with collar partial or lacking; birds lacking collars tend to have generally paler plumage. Juvenile very similar to collarless form of female in both plumage and structure. Race *brunnitorques* probably averages longer-winged; *griseifrons* is paler than *brunnitorques*, with sootier upperparts and

underparts as well as pale-fringed forehead, superciliary area and lores.

Habitat. Mainly montane, occurring up to 3400 m in Andes. Typical altitudinal range: Ecuador, W slope 500-3000 m (nesting up to 2300 m), E slope 500-2000 m; Mexico 1500-3000 m; will feed over lowlands, especially when rain falling in highlands, on occasions right down to sea-level. Main habitats defined as montane evergreen forest, secondary forest and second-growth scrub. Feeds over both forested and cleared areas, frequenting ravines and more gentle landscapes.

Food and Feeding. Specimens collected N Venezuela contained numerous *Crematogaster* ants. Highly gregarious. Often flocks with other swifts, especially *Streptoprocne zonaris* with which forms large pre-roosting flocks. Tends to forage in upper strata of mixed swift flocks, at least in Ecuador. In S Colombia (Cauca), recently seen feeding in mixed flocks with *S. zonaris*, *C. niger borealis*, *C. lemosi*, *C. cryptus* and *C. cherriei* on immense swarms of various small beetles during late Sept to early Oct.

Breeding. In Trinidad mainly May-Aug; in Colombia collected in breeding condition early Jun; in Costa Rica egg-laying mid-May to early Jul, not starting with first rains but delayed until heavier rains May/June; in Trinidad if another nesting attempt made during season, interval between ending of previous attempt and laying first egg of new clutch 0-25 days, majority 6-15. Closely associated with water, 50-300 cm above which it nests in shaded sites with humidity never falling below 95%; sea caves used in Trinidad; strong nest-site fidelity. Nest form varies with substrate, typically half-cupped with shallow central depression; consists almost entirely of mosses and liverworts with mud used at base or point of attachment; dry mosses and liverworts used as nest lining and may be added while nest in use; sited on tiny ledge, rock protrusion or niche on rock-face which can be overhanging or vertical. Mean nest measurements, Costa Rica: height 126 mm, width 104 mm, front to back 98.5 mm, central depression 31 x 66 mm. Two eggs; incubation 24-26 days; interval between deliveries of food to chicks typically at least 100 minutes; fledging 40-42 days. Average breeding success 36-40% with 0.9-1.3 young fledged per breeding effort.

Movements. Partial migrant. Resident South and Central America from Honduras N. Situation in Honduras, at least, may be equivocal as not known if wintering population there has bred farther N. Central American populations not reported in South America. Limited withdrawal in winter from N Mexico, especially high-altitude interior during Oct-Feb, at least, with apparent migrant flocks observed W Mexico, mid-Mar to May. Specimens from Guatemala taken from mid-Jul to Oct.

Status and Conservation. Not globally threatened. In general, considered to be a rather local species, apparently more abundant within its South American range, where it can regularly be encountered, often in larger numbers, than within its Central American distribution. However, species is locally common in Costa Rica and it appears to have been recorded more often in recent years from Panama. Recent research in Ecuador shows it to be at its greatest densities on the west temperate slope. Occurs in several protected areas throughout its extensive range, e.g. Monteverde Biological Reserve (Costa Rica), La Planada and Rio Nambi Reserves (Colombia), Podocarpus National Park (Ecuador) and Asa Wright Nature Centre (Trinidad); also regularly recorded at Macchu Picchu (Peru).

Bibliography. Beebe (1947, 1949), Belcher & Smoother (1936), Best & Clarke (1991), Best *et al.* (1993), Binford (1989), Bloch *et al.* (1991), Collins (1963, 1967a, 1967b, 1972a, 1974, 1980b), Fjeldså & Krabbe (1990), Gilliard (1941), Herklots (1961), Hilty & Brown (1986), Howell & Webb (1994, 1995a), Howell *et al.* (1997), Kiff *et al.* (1989), Krabbe & Somoza (1994), Marín (1993), Marín & Stiles (1992), Meyer de Schauensee & Phelps (1978), Monroe (1968), Navarro, Peterson, Escalante & Benítez (1992), Orton (1871), Phillips (1962), Remsen, Traylor & Parkes (1986), Ridgely & Gwynne (1989), Ridgway (1911), Rowley (1966, 1984), Salaman & Gandy (1994), Sick (1993, 1997), Slud (1964), Snow (1962a), Snow & Snow (1964), Snyder (1966), Stiles & Negret (1994), Stiles & Skutch (1989), Stotz *et al.* (1996), Vallety & Avers (1997), Wendelken & Martin (1986), Wetmore (1968a), Whitacre (1989), Whitney *et al.* (1994).

2. Tepui Swift

Cypseloides phelpsi

French: Martinet des tépui German: Phelpssegler Spanish: Vencejo de Tepui
Other common names: Phelps's Swift

Taxonomy. *Cypseloides phelpsi* Collins, 1972, Cerro Auyan-tepui, Bolívar, Venezuela.

Forms superspecies with *C. rutilus*. It has recently been suggested that these two species should be included in *Streptoprocne* due to similarities in clutch size, development of young, and plumage, and these details would certainly suggest a close link with that genus. Monotypic.

Distribution. S Venezuela (Amazonas, Bolívar), NW Guyana (Merume Mts) and mountains of Brazilian border with Venezuela (NE Roraima).

Descriptive notes. 16.5 cm; male 20-23 g, female 19-23 g. Medium-sized swift with stocky body, long, relatively broad wings, and broad, moderately forked tail, deeper than *C. rutilus*; very black plumage with bright orange throat and collar. Female has paler orange collar and throat. Juvenile has shallower tail-fork and prominent pale fringing across whole underparts. **Habitat.** Main habitats have been defined as montane evergreen forest, tropical lowland evergreen forest and low, seasonally wet grassland. Recorded within breeding range at 400-1400 m, and from 1100 m as a vagrant. Often recorded in mixed flocks with *Streptoprocne zonaris*.

Food and Feeding. Not known.

Breeding. Late spring to early summer breeding season has been postulated. Recorded nest is truncated cone consisting of live moss sited on vertical wall, 1.5 m above floor, of small cave among boulders at edge of small stream.

Movements. Resident in Pantepui. Record from Aragua, N Venezuela, suggests some degree of dispersal.

Status and Conservation. Not globally threatened. Restricted-range species: present in Cordillera de la Costa Central EBA and Tepuis EBA. Commonly encountered in Venezuela in Cerro Tamacuari region (Amazonas); also regularly recorded at La Escalera (Bolívar).

Bibliography. Barrowclough, Escalante *et al.* (1995), Barrowclough, Lenino & Sweet (1997), Collins (1972a), Dickerman & Phelps (1982), Gilliard (1941), Meyer de Schauensee & Phelps (1978), Navarro, Peterson, Escalante & Benítez (1992), Sick (1993, 1997), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Whitacre (1989), Willard *et al.* (1991).

3. Black Swift

Cypseloides niger

French: Martinet sombre German: Schwarzsegler Spanish: Vencejo Negro

Taxonomy. *Hirundo nigra* J. F. Gmelin, 1789, Hispaniola.

Previously placed in genus *Nephocetes*. Forms superspecies with *C. lemosi*, *C. rothschildi* and *C. fumigatus*. Darkness of plumage varies within range of nominate; proposed race *jamaicensis*, from S West Indies, now considered synonymous with nominate. Three subspecies currently recognized.

Subspecies and Distribution.

C. n. borealis (Kennerly, 1858) - W North America S to SW USA; winters in South America.

C. n. costaricensis Ridgway, 1910 - C Mexico S to Costa Rica; winters S of Mexican Isthmus.

C. n. niger (J. F. Gmelin, 1789) - West Indies to Trinidad.

Descriptive notes. 18 cm; 35-45 g. Rather a large swift with shallow, though distinctly, forked tail; long, broad wings and stocky body; dark plumage with white fringes to underparts, though these are sometimes lacking. Female has broader white fringing to underparts. Juvenile shows broad, white, rather spotty fringes on underbody. Race *borealis* is larger with strikingly black plumage, notably paler, grey head, especially forehead, and more prominent white fringing on underparts; *costaricensis* is generally darker and smaller than *borealis*.

Habitat. Occurs mainly at 1200-3000 m in Mexico; breeds 555-1400 m in S California,

and from close to sea-level up to 2600 m in British Columbia. In West Indies prefers forested highlands. In continental N America occurs over variety of open highland habitats. Occasionally seen in lowlands. Post-breeding flocks occur up to 3350 m in C Sierra Nevada, California. Main Neotropical habitats defined as edge of montane evergreen forest and secondary forest.

Food and Feeding. Studies reveal Hymenoptera predominate in diet; 276 prey items from 2 adults consisted of 4 species of Hymenoptera, including 200 individuals of a species of winged ant. Diet provided by adults to young in British Columbia was dominated by ants (Formicidae), nestling stage being timed to coincide with swarms of flying ants. Rain in highlands can force feeding to occur in lowlands. Highly gregarious, sometimes in flocks numbering thousands. In some areas parents breeding in mountainous areas travel many kilometres to lowland feeding sites. Race *borealis* collected at 1800 m in S Colombia where it was feeding in mixed flocks with *Streptoprocne zonaris*, *C. rutilus*, *C. lemosi*, *C. cryptus* and *C. cherriei* on immense swarms of various small beetles during late Sept to early Oct.

Breeding. Collected in breeding condition Costa Rica May-Jul and Dominica Jun-Jul; mating Jun, Cascade Mts (SW Canada, NW USA), with breeding behaviour Jul to early Aug; eggs in British Columbia from late Jun, in California mid-Jun to late Jul (peaking end Jun to early Jul), and in Costa Rica late May; small colony in Veracruz, Mexico, had nests with nestlings Jul; active colonies in Colorado Jul-Aug; nests with young in Montana late Jul. Single-brooded. Nest-sites have 6

On following pages: 4. White-chested Swift (*Cypseloides lemosi*); 5. Rothschild's Swift (*Cypseloides rothschildi*); 6. Sooty Swift (*Cypseloides fumigatus*); 7. Spot-fronted Swift (*Cypseloides cherriei*); 8. White-chinned Swift (*Cypseloides cryptus*); 9. White-fronted Swift (*Cypseloides storeri*); 10. Great Dusky Swift (*Cypseloides senex*); 11. White-collared Swift (*Streptoprocne zonaris*); 12. Biscutate Swift (*Streptoprocne biscutate*); 13. White-naped Swift (*Streptoprocne semicollaris*).

requirements: most often high relief, water, inaccessibility, darkness, unobstructed flyway immediately in front, and rock niche to build nest on. In British Columbia, nests found on canyon walls near water, especially waterfalls; typically nests on rock ledge beneath overhanging moss. Nest a pad of moss with lesser amounts of twigs and pine needles, bound with mud; ferns and seaweed also used depending on availability. One nest measured 140 mm wide, 100 mm back to front and 20 mm deep. May copulate in flight. Clutch normally 1 egg, occasionally 2; no replacement laying, if egg lost; incubation 23-27 days; young fed once or twice daily, typically at dusk by each parent; fledging period c. 45 days with brood dates in British Columbia from mid-Jul to mid-Sept.

Movements. Definite wintering grounds for any race uncertain. May be resident in Greater Antilles, though breeding visitor only to Puerto Rico from late Mar to mid-Aug. Present in Lesser Antilles from Mar/Apr to Aug/Sept. Records in Jun from Guyana and in Jul from Trinidad apparently contradict theory that nominate race winters in Guyana. Absent in winter from Costa Rica, no certain records Nov-Mar, and majority, at least, leave Mexico N of Isthmus from Oct to Feb. Race *borealis* now known to winter somewhere in South America, as recorded late Sept to early Oct in Cauca, S Colombia. Migration from Central America to South America may be in part over Pacific, records offshore including 135 km off Guatemala's Pacific coast. Main spring arrivals: S California mid-May, British Columbia mid-late May to Jun. Main return migration: British Columbia late Aug to mid-Sept, S California late Aug to Oct. Rarely recorded from SE Farallon Is (42 km W of San Francisco) mid-Jun and early Aug to early Oct. Race *borealis* occurs on Mexican Pacific slope Apr-May and Aug-Sept and offshore from Baja California S. Migration may occur Costa Rica Apr to early May and Sept to early Oct. Often migrates in large flocks, with groups of 300-400 noted during spring migration in California. Summer escape movements associated with passage of cyclones in British Columbia. Vagrant to E USA N to Massachusetts.

Status and Conservation. Not globally threatened. Abundance varies throughout range. Locally frequent to common in Mexico, rare and very localized in California, fairly common to locally very abundant in coastal British Columbia. Recent survey work revealed a significant downward trend (-9.1% p.a.) in Canadian population over 1966-1995, though an apparently larger significant upward trend (+24.3% p.a.) in US numbers during 1980-1995. Estimated S Californian population in 1985 and 1986 was 28 and 26 adults respectively, though largest Californian colony more recently has held over 20 pairs. High breeding success noted in this population; small numbers apparently due to lack of suitable nesting sites.

Bibliography. 4. White-chested Swift

Cypseloides lemosi

French: Martinet à plastron blanc **German:** Brustflecksegler **Spanish:** Vencejo Pechiblanco
Other common names: Giant Swift

Taxonomy. *Cypseloides lemosi* Eisenmann and Lehmann, 1962, Santander, Colombia. Previously placed in genus *Nephaocetes*. Forms superspecies with *C. niger*, *C. rothschildi* and *C. fumigatus*. Monotypic.

Distribution. SW Colombia in upper Cauca Valley, departments of Valle and Cauca. Also recently recorded in NC Colombia, NE Ecuador and NW Peru.

Descriptive notes. 14 cm; 29 g. A medium-sized swift with long, broad wings and a distinctly forked tail; blackish plumage, especially upperparts where forehead only slightly paler, with diagnostic white chest patch. Female has shallower tail-fork; chest patch reduced, or sometimes even missing; variable extents of pale fringing on underparts. Juvenile similar to female but with shallower tail-fork.

Habitat. All previous records, including tentative Ecuadorian sightings, were at 1050-1300 m, but species recently seen at 1800 m in Cauca, C Andean foothills, foraging over undulating plain cut through by R Blanco and R Cauca. Collected over highly eroded grassy hills with sparse scrubby cover. Seen once over level pasture. Main habitats defined as secondary forest and second-growth scrub.

Food and Feeding. Observed in, and collected from, either monospecific flocks or flocks including *C. rutilus*, *C. cryptus* or *Streptoprocne zonaris*. All published Colombian records of flocks have been of 20-25 birds. First of recent probable records from Ecuador was of 2 seen in flock of c. 150 *Cypseloides* swifts feeding in early morning at elevation of 50-100 m. Recently observed feeding in mixed flocks with *Streptoprocne zonaris*, *C. rutilus*, *C. niger borealis*, *C. cryptus* and *C. cherriei* on immense swarms of various small beetles during late Sept to early Oct in S Colombia.

Breeding. Not known.

Movements. Recorded in range from Feb to May and Oct and suspected to be resident.

Status and Conservation. **VULNERABLE.** Restricted-range species; present in Colombian Inter-Andean Valleys EBA. Known from only a handful of specimens and field sightings. Located near Cerro Munchique in 1962, and again more recently, and a population may persist there. Recently recorded from several new sites, where status remains unclear: 12 birds at Río Suárez, NC Colombia, in 1989; probable records from Napo Province, NE Ecuador; and first Peruvian record, Cordillera del Condor, NW Peru. Very little known of species' ecological requirements; until this lack of data has been rectified, effect of expanding area of eroded habitat within range will remain unknown. It has been suggested that use of agrochemicals may be affecting populations.

Bibliography. Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Eisenmann & Lehmann (1962), Hilty & Brown (1986), Meyer de Schauensee (1982), Navarro, Peterson, Escalante

& Benítez (1992), Olrog (1968), Schulenberg & Awbrey (1997), Stattersfield *et al.* (1998), Stiles & Negret (1994), Stotz *et al.* (1996), Wege & Long (1995).

5. Rothschild's Swift

Cypseloides rothschildi

French: Martinet de Rothschild **German:** Rothschildsegler **Spanish:** Vencejo Parduzco
Other common names: Giant/Great Swift

Taxonomy. *Cypseloides rothschildi* Zimmer, 1945, Tucumán, Argentina.

Forms superspecies with *C. niger*, *C. lemosi* and *C. fumigatus*. Sometimes considered conspecific with *C. fumigatus*, and possibly *C. cryptus*. Older name for species, "*C. major*", is preoccupied by a synonym of *C. senex*. Monotypic.

Distribution. NW Argentina, in Salta, Tucumán and Santiago del Estero. Speculated to occur in Bolivia and Peru; single record from Cuzco, Peru.

Descriptive notes. 15 cm. A medium-sized swift with long, broad wings and a short, rather square tail; very uniform mid-brown all over. In the hand, separable from *C. fumigatus* by soft tail, which lacks stiffened or protruding father shafts; paler plumage and longer wings on average.

Habitat. In general, not very well known. Species is believed to occur exclusively within an altitude range of 500-2000 m. A flock of swifts, believed to be of present species, was recorded over an arid intermontane valley at 1500 m in W Santa Cruz, Bolivia. Main habitat has been defined as montane evergreen forest.

Food and Feeding. No information available.

Breeding. No information.

Movements. Resident. It has been suggested that Cuzco record does not refer to dispersal or vagrancy but that species' range includes Peru, but others believe it may winter N to Bolivia and Peru. A flock, c. 30, possibly of this species was recorded in Santa Cruz, Bolivia, in mid-Mar.

Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species; present in Argentina and South Bolivian Yungas EBA. No precise information regarding population size or trends. Species can sometimes be seen along road between Salta and Humahuaca, Argentina.

Bibliography. Canevari *et al.* (1991), Collar *et al.* (1994), Eisenmann & Lehmann (1962), Fjeldså & Mayer (1996), Narosky & Yzurieta (1993), Navarro, Peterson, Escalante & Benítez (1992), Nore & Salvador (1985), Olrog (1963a), de la Peña (1994), Remsen & Ridgely (1980), Short (1975), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Zimmer (1945b, 1953b).

6. Sooty Swift

Cypseloides fumigatus

French: Martinet fuligineux **German:** Rauchsegler **Spanish:** Vencejo Negruczo

Taxonomy. *Hemiprocne fumigata* Streubel, 1848, Brazil.

Forms superspecies with *C. niger*, *C. lemosi* and *C. rothschildi*. Sometimes considered conspecific with *C. rothschildi*, and possibly *C. cryptus*. Monotypic.

Distribution. E Bolivia (Santa Cruz) through E Paraguay (Oriente) and extreme NW Argentina (Misiones) to SE Brazil (Espírito Santo S to Rio Grande do Sul).

Descriptive notes. 15 cm; 44 g. A medium-sized swift with a short, square tail and rather long wings; plumage generally sooty black-brown all over, with a tendency towards a paler forehead.

Habitat. Main habitats have been defined as montane evergreen forest, tropical lowland evergreen forest, southern temperate forest and second-growth scrub. Recorded at 700-2100 m. Closely associated with waterfalls and could be found over any nearby habitat within range.

Food and Feeding. Species has usually noted foraging in small groups of 3-6 birds, and has

been seen in association with *Chaetura* and *Streptoprocne* swifts. Up to 100 individuals noted at a single roost in Paraguay.

Breeding. Collected in breeding condition Rio Grande do Sul in early Oct and early Nov. Nests on canyon walls. Nest is conical structure of moss, pebbles and mud, lined with ferns. One egg.

Movements. Resident. Observations suggest that in Oriente, Paraguay, it may be partially migratory, with influx of birds in spring.

Status and Conservation. Not globally threatened. Probably commoner than previously supposed, as a result of identification difficulties. Scarce resident in E Paraguay, though regular at Aguara Nu, Mbaracayú Forest Nature Reserve, where population apparently swells with arrival of spring migrants. Not uncommon in NW Argentina and SE Brazil; range could extend through regions of S Brazil between mapped areas. Occurs in Serra dos Orgãos, Itatiaia and Aparados da Serra National Parks, Brazil.

Bibliography. Anon. (1993a), Belton (1984), Brooks, Barnes *et al.* (1993), Brooks, Clay *et al.* (1995), Canevari *et al.* (1991), Chebez (1994), Clay *et al.* (1998), Dabbene (1981), Eisenmann & Lehmann (1962), Hayes (1995), Lowen, Bartrina, Clay & Tobias (1996), Lowen, Clay *et al.* (1997), Narosky & Yzurieta (1993), Navarro, Peterson, Escalante & Benítez (1992), Olrog (1979b), Pacheco *et al.* (1996), Reboratti (1918), do Rosário (1996), Sick (1993, 1997), Stotz *et al.* (1996), Tobias *et al.* (1993), Whitacre (1989), Zimmer (1945b).

7. Spot-fronted Swift

Cypseloides cherriei

French: Martinet à points blancs **German:** Diademsegler **Spanish:** Vencejo Cuatro-ojos
Other common names: Cherrie's Swift

Taxonomy. *Cypseloides cherriei* Ridgway, 1893, Volcán de Irazú, Costa Rica.

Monotypic.

Distribution. Scattered and poorly known: Costa Rica (Cordillera Central on Pacific slope); N Venezuela (Aragua, coastal cordillera); NC & SW Colombia (San Gil, Santander; Changuayaco by Cerro Munchique and Las Guacas near Popayán, in W Andes of Cauca) and N Ecuador (Pichincha, W slope of Andes).

Descriptive notes. 14 cm; 23 g. Small swift with short square tail and relatively short wings; blackish plumage with striking head pattern; white supraloral patch, post-ocular streak and pale fringes over eye-patch. Browner individuals may be first-summer or have retained juvenile plumage. Juvenile as fresh adult but fringing on underbody broader, remiges narrowly fringed greyish white, and post-ocular spot smaller.

Habitat. Not recorded outside mountainous areas; all localities 1100–2200 m. Main habitat defined as montane evergreen forest. Occurs in forested uplands with deep valleys. In Costa

Rica especially favours deep gorges; also recorded foraging over brushy savanna at Helecheles. **Food and Feeding.** Of 719 prey items analysed, from 2 boluses and 2 stomachs, 87% were Hymenoptera and Hemiptera. In Costa Rica occurs singly or in pairs, often in association with *C. rutilus*. Tends to forage in higher strata of mixed swift flocks. A number have been recorded after sunset during thick fog, at Rancho Grande, Venezuela, where they were attracted to lights. It has been suggested that *Cypseloides* feed later than other sympatric genera and can experience problems reaching suitable roosting areas when caught in inclement weather. Recently observed feeding in mixed flocks with *Streptoprocne zonaris*, *C. rutilus*, *C. cryptus*, *C. lemosi* and *C. niger borealis* on immense swarms of various small beetles during late Sept to early Oct, in department of Cauca, Colombia.

Breeding. In Venezuela active nests recorded Jul–Aug; in Ecuador c. 18-day-old chick in nest in mid-Jun and hatching period for that country thought to be late Apr to early Jun; in Costa Rica egg-laying late May to mid-Jul, stimulated not by first rains of season but by heavier falls of May/June; strong nest-site fidelity. Widest variation in nest-site of all well-studied *Cypseloides*; form also differs with site type, though typically cupped or half-cupped depending on width and angle of support; nest 1–5 m above water; typically moderately to fully saturated, though some drier, consisting of mosses and liverworts with lining of dry bamboo leaves and ferns; where bryophytes not readily available coarse vegetable fibres employed to great extent in construction and as lining. Most substantial in wettest situations with greatest volume of mud in base, though normally less substantial with only bare minimum of material to form nest cup; typically on rock knob or narrow ledge sloping outwards at 45° and protected by overhang; mean height 56 mm, width 104 mm, front to back 68 mm, depression 18 mm deep × 64 mm wide × 40 mm front to back. Two nests in Ecuador were 3 m apart with Andean Cock-of-the-Rock (*Rupicola peruviana*) nest close by. Single egg; incubation period in Costa Rica 26–28 days; nestling period 65–70 days.

Movements. No indication of migratory behaviour.

Status and Conservation. Not globally threatened. Despite paucity of sightings, specimens and recorded localities, present species may prove to be more widespread and abundant than currently thought, though it certainly appears to be one of the rarer Neotropical swifts.

Bibliography. Beebe (1949), Chantler (1998), Collins (1967c, 1968b, 1980b), Hilty & Brown (1986), Kiff (1975), Marín (1993), Marín & Stiles (1992, 1993), Meyer de Schauensee (1982), Meyer de Schauensee & Phelps (1978), Navarro, Peterson, Escalante & Benítez (1992), Olog (1968), Slud (1964), Stiles & Negret (1994), Stiles & Skutch (1989), Stotz *et al.* (1996), Whitacre (1989), Zimmer (1945b).

8. White-chinned Swift

Cypseloides cryptus

French: Martinet à menton blanc **German:** Weißkinnssegler **Spanish:** Vencejo Barbiblanco
Other common names: Zimmer's Swift

Taxonomy. *Cypseloides cryptus* Zimmer, 1945, Inca Mine, Peru.

Forms superspecies with *C. storeri*, and the two are sometimes considered conspecific. Another proposal suggests that present species might be conspecific with *C. rothschildi* and *C. fumigatus*. Monotypic.

Distribution. Scattered and poorly known: in Central America, occurs primarily on Caribbean slope lowlands of Belize, Honduras, Nicaragua, Costa Rica and Panama; recorded from Andes and associated lowlands in Peru, Ecuador, Colombia and Venezuela; also cordilleras of N Venezuela, and tepuis of S Venezuela and Guyana.

Descriptive notes. 15 cm; 35 g. A medium-sized swift with a rather squat appearance and a relatively short, square tail; generally blackish with pale grey areas on chin, distal part of forehead, and lores, as well as line over eye, though this is very hard to see in field. Brown individuals, possibly still in juvenile plumage, have a reduced chin patch. Tail relatively shorter than in smaller *C. cherriei*.

Habitat. Main habitats defined as montane evergreen forest and tropical lowland evergreen forest. Prefers uplands with gorges and waterfalls, which it uses for both roosting and breeding. Taken at Helecheles, Costa Rica, between

1000–1500 m in habitat containing brushy savanna, some agriculture and humid primary forest. Occurs between sea-level and 3000 m.

Food and Feeding. Analysis of prey items from 4 stomachs and 2 boluses showed that 92% were Hymenoptera. Two females collected from N Venezuela contained many *Azteca* ants, and one of these also many *Crematogaster* ants. Less highly gregarious than other species, though often with other *Cypseloides* and *Streptoprocne* swifts and more occasionally other genera. Feeds in higher strata when foraging with other swift species. Recently seen feeding in mixed flocks with *Streptoprocne zonaris*, *C. rutilus*, *C. niger borealis*, *C. lemosi* and *C. cherriei* on immense swarms of various small beetles during late Sept to early Oct in S Colombia.

Breeding. In Costa Rica egg-laying from early May to early Jun prompted not by first rains of wet season but by heavier rains May–Jun; strong nest-site fidelity. Site closely associated with falling

water and typically protected by permanently wet *Pilea* sp., occasionally mosses or liverworts. Permanently saturated nest consists of mosses and liverworts with highest percentage of mud in base; shallow bowl or half-cup, mean measurements 76.5 mm front to back, 107 mm wide, 48 mm high; depression 49.5 mm front to back × 65.5 mm wide × 13.5 mm deep. Single egg; incubation period, Costa Rica, c. 30 days; nestling period 55–58 days.

Movements. Resident.

Status and Conservation. Not globally threatened. Generally uncommon, with rather scattered distribution, and definitely known from very few sites, e.g. in Colombia from Cauca and Córdoba, in Venezuela from Táchira, Aragua and Bolívar. At best-known breeding site in Costa Rica, low density of species is apparent.

Bibliography. Beebe (1947, 1949), Chantler (1998), Collins (1968b), Eisenmann & Lehmann (1962), Hilty & Brown (1986), Howell, S.N.G. & Webb (1995a), Howell, S.N.G., Dowell *et al.* (1992), Howell, S.N.G., Snetsinger & Wilson (1997), Howell, T.R. (1957), Kiff (1975), Marín (1993), Marín & Stiles (1992), Meyer de Schauensee & Phelps (1978), Monroe (1968), Navarro, Peterson, Escalante & Benítez (1992), Ridgely & Gwynne (1989), Slud (1964), Snyder (1966), Stiles & Negret (1994), Stiles & Skutch (1989), Stotz *et al.* (1996), Wetmore (1968a), Whitacre (1989), Zimmer (1945b).

9. White-fronted Swift

Cypseloides storeri

French: Martinet de Storer **German:** Weißstirnsegler **Spanish:** Vencejo Frentiblanco
Other common names: White-faced Swift

Taxonomy. *Cypseloides storeri* Navarro *et al.*, 1992, Puerto del Gallo, Guerrero, Mexico.

Forms superspecies with *C. cryptus*. Much debate surrounds status of this form (see page 416); considered a race of *C. cryptus* by some authorities. Monotypic.

Distribution. SW Mexico in mountains of Michoacan, Guerrero and Jalisco.

Descriptive notes. 14 cm; 39.5 g. Medium-sized swift with short square tail and squat body; sooty black-brown with greyish chin, lores and forehead. Structure and plumage very like *C. cryptus*; in hand, these two species may be identified by tail/tarsus ratio, present species 36.5 and *C. cryptus* 34–36; present species also differs from latter by whitish, not sooty, post-orbital feathers and more abruptly terminating face pattern.

Habitat. Collected at 1500–2500 m in forested areas with numerous waterfalls and ravines. Guerrero habitat classified as montane cloud-forest, whereas Michoacan forest where collection occurred is transitional between pine-oak and dry tropical deciduous. Possibly sighted with large numbers of *Streptoprocne semicollaris* and *C. rutilus* entering waterfall roost site. Probable individual observed at Tacambaro was seen flying over hills and fields cut through by a narrow steep-sided canyon at 1200 m.

Food and Feeding. Not known. A presumed individual of this species was observed in a flock of c. 100 swifts comprising 80–90 *C. rutilus*, 4 *C. niger* and 1 *Chaetura vauxi*.

Breeding. No information.

Movements. Lack of information makes migratory status equivocal. May be resident or breeding visitor during Jul–Sept, possibly May.

Status and Conservation. Not globally threatened. Data-deficient. Restricted-range species: present in Sierra Madre Occidental and Trans-Mexican Range EBA and Sierra Madre del Sur EBA. Known from only 5 specimens and 1 probable sight record. Lack of sightings of unidentified dark *Cypseloides* within range combined with paucity of museum specimens suggests rarity.

Bibliography. Anon. (1998a), Chantler (1998), Collar *et al.* (1994), Hernández-Baños *et al.* (1995), Howell (1993d), Howell & Webb (1995a), Howell *et al.* (1997), Navarro, Benítez *et al.* (1993), Navarro, Peterson, Escalante & Benítez (1992), Peterson & Navarro (1993), Stattersfield *et al.* (1998), Stotz *et al.* (1996).

10. Great Dusky Swift

Cypseloides senex

French: Martinet à tête grise **German:** Rußsegler **Spanish:** Vencejo Canoso

Taxonomy. *Cypseloides senex* Temminck, 1826, Brazil.

Due to differences in tail and foot structure, species has been placed in genus *Aerornis*, either alone or with *Streptoprocne semicollaris*. Monotypic.

Distribution. C & S Brazil, E Paraguay (Oriente) and N Argentina (Misiones); may also breed in Serranía de Huanchaca, NE Bolivia, where recently recorded.

Descriptive notes. 18 cm; 60–98 g. Large swift with square or slightly rounded tail, long broad wings and bulky body; brown with paler head (forehead can appear quite whitish) and slightly paler rump. Juvenile has comparatively pale median primary coverts.

Habitat. Breeds and roosts around waterfalls, feeding over nearby habitats. Recorded from lowlands to 1000 m. Recent record from Bolivia was at 180 m altitude.

Food and Feeding. Feeds high over forest canopy during day. Gregarious, often associating with *S. zonaris*.

Breeding. Colonial, nesting on horizontal ledges adjacent to or behind waterfalls, often in direct sunlight. Nests are disc-shaped cones of moss and pebbles bound together with mud.

Movements. Equivocal migratory status. Generally believed to be resident. Some authors have suggested transequatorial migration on strength of “probable” sightings from Iquitos, Peru. Records from Bolivia in Noel Kempff Mercado National Park and Serranía de Huanchaca may refer to undiscovered breeding populations.

Status and Conservation. Not globally threatened. Generally common to locally abundant, though scarce to uncommon in Paraguay. Large numbers breed at Falls of Iguaçu, in area on Brazil–Argentina border; also present in several other protected areas, e.g. Noel Kempff Mercado National Park

(Bolivia), Ybicuí National Park and La Golondrina and Estancia Itabo Private Nature Reserves (Paraguay) and Serra da Canastra National Park (Brazil). Future of certain sites may be threatened by dam building.

Bibliography. Allen (1893), Brooks *et al.* (1993), Canevari *et al.* (1991), Chebez (1993b, 1994), Dubs (1992), Hayes (1995), Hayes & Scharf (1995a), Hilty & Brown (1986), Narosky & Yzurieta (1993), Navarro, Peterson, Escalante & Benítez (1992), de la Peña (1982, 1994), Saibene *et al.* (1996), Schubart *et al.* (1965), Sick (1993, 1997), Stotz *et al.* (1996), Whitacre (1989), Whitney *et al.* (1994), Zimmer (1945b).

Genus *STREPTOPROCNE* Oberholser, 1906

11. White-collared Swift

Streptoprocne zonaris

French: Martinet à collier blanc **German:** Halsbandsegler **Spanish:** Vencejo Acollarado
Other common names: Collared/Antillean Cloud/Giant White-collared/Ringed Swift

Taxonomy. *Hirundo zonaris* Shaw, 1796, Brazil.

Recent research has shown that race *albicincta* is far more restricted in range than previously thought. Nine subspecies recognized.

Subspecies and Distribution.

S. z. mexicana Ridgway, 1910 - S Mexico to Belize.

S. z. bouchellii Huber, 1923 - Nicaragua to Panama.

S. z. pallidifrons (Hartert, 1896) - Greater Antilles and locally in Lesser Antilles (Saba, Grenadines, Grenada).

S. z. minor (Lawrence, 1882) - Cordillera of coastal N Venezuela, recorded to Trinidad.

S. z. albicincta (Cabanis, 1862) - lowland Venezuela (S of Andes and cordilleras), Guyana and possibly Surinam and French Guiana.

S. z. subtropicalis Parkes, 1993 - middle elevations in Andean highlands from Mérida (Venezuela) and Colombia to Peru.

S. z. altissima Chapman, 1914 - high elevations of Andes in Colombia and Ecuador.

S. z. kuenzeli Niethammer, 1953 - high elevations of Bolivian Andes and NW Argentina.

S. z. zonaris (Shaw, 1796) - S Brazilian and Bolivian lowlands, and C & E Paraguay.

Descriptive notes. 22 cm; 104 g. Large swift with sturdy body, broad wings and shallowly forked tail; blackish plumage broken by distinctive white collar. Juvenile shows extensive white fringing to body feathers and mottled collar. Race *subtropicalis* is smaller and more deeply black, with broader white collar; *albicincta* is small, with broad breast band and restricted buff fringing; *mexicana* large with greyer underparts and broad breast band; *bouchellii* blacker than latter with narrower breast band; *minor* with narrow, often mottled, breast band and greyish throat; *pallidifrons* with face and sometimes throat contrastingly pale,

and buff-fringed marginal coverts, especially juvenile; *altissima* very large with very broad collar, black plumage, slightly paler throat and white-fringed marginal coverts; *kuenzeli* has brownish underparts and distinct pale fringing on marginal coverts and superciliary area.

Habitat. Within large range often montane or submontane, to 4350 m in Andes, and from sea-level to 2500 m in Mexico; breeds only on those Caribbean islands with terrain over 2000 m. However, does occur over variety of lowland and highland habitats, coastal and interior. Widest altitudinal range of any Ecuadorian swift: 300-4000 m, to 4200 m on E slope, equally abundant throughout. Main habitats defined as montane evergreen forest, tropical lowland evergreen forest, secondary forest and second-growth scrub. Least abundant in arid regions. Over open, scrubby habitat, Rio Negro Preserve, Costa Rica, and over broadleaved forest, pine ridge and savanna, Hill Bank, N Belize. During habitat study in Villavieja area, Colombia, found over wide range of habitats, including residential, with exception of rice fields.

Food and Feeding. Two digestive tracts obtained in Mexico contained 842 and 538 individual insects with 1 spider, Orders Hemiptera, Hymenoptera, Coleoptera, Lepidoptera and Diptera and suborder Homoptera were found in both tracts, and 811 and 471 of the prey items respectively were 1 ant species (*Azteca foreli*), indicating importance of swarming insects. Highly gregarious, often seen in large flocks with other swift genera. Frequently associates with *Chaetura vauxi* in Sierra de Tuxtla, Mexico, in flocks of 10-200. Forages daily over wide range, and localized weather-stimulated migrations are well established. Will feed low over cities if rain falling in typically favoured upland habitats nearby. Feeds higher than other swift species when present at same site in Ecuador.

Breeding. Adults in breeding condition, Rio Grande do Sul, early Oct; sexually active, Bolivia, Oct; eggs recorded in Ecuador, Jan; egg-laying begins in Costa Rica mid-Apr, peaking late Apr and finished by mid-May, probably stimulated by first rains; egg-laying at Mexican colony, early May; pullus recorded Tolima, Colombia, Apr and Venezuelan Andes, May-Jun. In Costa Rica nest-building starts in dry season. Nests singly or in colonies of up to 12 pairs. Nest-sites require darkness and solid, more or less horizontal, surface, typically caves next to or behind waterfalls; caves vary in size up to 1 m wide at entrance and several metres deep, entrances often screened by vegetation; often nests in spray of falling water. Typical nests are disc-shaped pads with shallow central depression, of mud and vegetable matter, mainly rootlets, mosses and liverworts, sometimes lined with vegetable fibres, fine mosses or even dry leaves; nest base typically wet, upper nest moist; occasionally no nest structure employed and eggs laid directly onto substrate; mean height 95 mm, central depression mean width 147 mm, depth 10 mm. Two eggs; incubation period c. 30-35 days; chicks apparently fed only once per day; nestling period c. 45-55 days.

Movements. Partly migratory, with various forms of dispersal in different populations. Some altitudinal dispersal into lowlands from Andean populations, May-Aug, in Peru. Noted in so-called "fire-following" movements, i.e. systematic exploitation of seasonal savanna fires in campo regions of South America. Chaco habitats in Bolivia used by non-breeding birds. Status in Argentina away from Andean breeding range of *kuenzeli* uncertain: may occur across N Argentina outside breeding season. Rare visitor to Grenada, May-Oct. Known to occur in S Petén, Guatemala, only in winter. Irregular visitor to Mexico N to Colima and Jalisco, Dec-Mar. Recorded in USA from California to Florida.

Status and Conservation. Not globally threatened. Locally common to abundant throughout much of extensive range, though race *pallidifrons* of West Indies scarce in parts, and species rare in some areas of Central America, especially on Pacific coast; extremely rare in N Belize, though abundant in suitable habitat in Costa Rica; uncommon in some parts of Andes. Occurs in numerous protected areas throughout extensive range, e.g. Braulio Carrillo, Volcán Irazú and Volcán Poás National Parks and Monteverde Biological Reserve (Costa Rica), Río Nambi National Reserve (Colombia), and Serra dos Órgãos and Itatiaia National Parks (Brazil); also in Ybicuí National Park (Paraguay), where uncommon.

Bibliography. Andrie (1967), Barbour (1943), Beavers *et al.* (1991), Becker & López (1997), Beebe (1947), Belton (1984), Best & Clarke (1991), Best *et al.* (1993), Binford (1989), Bloch *et al.* (1991), Canevari *et al.* (1991), Contreras *et al.* (1990), Cooper (1997), Cuello & Gerzenstein (1962), Erickson *et al.* (1989), Fjeldså & Krabbe (1990), Gardner (1972), Garrido & de la Cruz (1990), Hardy & Clench (1982), Haverschmidt & Mees (1994), Hayes (1995), Herklots (1961), Hilty & Brown (1986), Howell (1993b), Howell & Webb (1994, 1995a), Johnson (1967), Kepler (1972), Kirwan (1996b, 1996c), Krabbe & Sornoza (1994), Kratter *et al.* (1993), Lasley (1984), Lee *et al.* (1996), Marín (1993), Marín & Carrión (1994), Marín & Stiles (1992), McKay (1980), Meyer de Schauensee & Phelps (1978), Monroe (1968), Munves (1975), Nellar (1993), Parkes (1993), de la Peña (1982, 1994), Peres & Whittaker (1991), Raffaele *et al.* (1998), Remsen, Traylor & Parkes (1986), Ridgely & Gaulin (1980), Ridgely & Gwynne (1989), Ridgway (1910, 1911), Rogers (1939a), do Rosário (1996), Rowley & Orr (1962, 1965), Russell (1964), Saibene *et al.* (1996), Salaman & Gandy (1994), Sick (1948c, 1993, 1997), Slud (1964), Snow (1962a), Snyder (1966), Stiles & Skutch (1989), Stotz *et al.* (1996), Thomas (1993), Turner (1981), Valley & Whitman (1997), Wetmore (1957a, 1968a), Wetmore & Swales (1931), Whitacre (1989, 1992), Whitacre & Ukrain (1982), Zimmer (1945, 1953b).

12. Biscutate Swift

Streptoprocne biscutate

French: Martinet à collier interrompu **Spanish:** Vencejo Nuquiblanco Brasileño
German: Schildsegler

Taxonomy. *Chaetura biscutate* P. L. Sclater, 1865, Rio de Janeiro and Ypanema, São Paulo, Brazil. Two subspecies recognized.

Subspecies and Distribution.

S. b. seridoensis Sick, 1991 - Seridó, NE Brazil.

S. b. biscutate (P. L. Sclater, 1865) - Minas Gerais S to Rio Grande do Sul, E Brazil; also recorded in Paraguay and N Argentina.

Descriptive notes. 22 cm; 85-100 g. Large swift with long broad wings, sturdy body and square tail; black-brown with white nape and white upper-breast patches; paler fore-face and sometimes throat. Grey-white fringing to plumage in adult. Race *seridoensis* smaller than nominate.

Habitat. Main habitats have been defined as tropical lowland evergreen forest, montane evergreen forest, southern temperate forest, second-growth scrub and tropical deciduous forest. Roosts and breeds in dry caverns; foraging noted around waterfalls. Occurs between lowlands and c. 2500 m; breeds at 1600 m in

Ibitipoca Park.

Food and Feeding. Highly gregarious, frequently feeding in numbers around waterfalls. Where sympatric with *S. zonaris*, such as Itatiaia Mts, Rio de Janeiro, the two species do not readily associate.

Breeding. Season in Minas Gerais, Oct-Dec; birds in breeding condition, Rio Grande do Sul, early Oct. Nests on horizontal ledges in large dry caverns; nest is shallow, bowl-shaped disc of lichens, mosses and dry leaves.

Movements. Not fully understood. Breeding areas of Seridó roosting population (*seridoensis*) undiscovered. Nominate race arrives Minas Gerais from Aug, with some still present Feb, but wintering grounds unknown; possibly a transequatorial migrant.

Status and Conservation. Not globally threatened, though it has been suggested that population requires monitoring. Common to abundant, Rio Grande do Sul. At Seridó, 90,000-100,000 roosted at 1 cave at Serra do Bico da Arara in Aug 1978, and 1200 were reported roosting in 15 caves in 1984. Occurs in Chapada dos Guimarães and Aparados da Serra National Parks (Brazil). First record for Paraguay from Aguaraçu, Nov 1997.

Bibliography. de Andrade *et al.* (1985), Belton (1984), Canevari *et al.* (1991), Chebez (1994), Clay *et al.* (1998), Erickson *et al.* (1989), Hilty & Brown (1986), Norez & Yzurieta (1985), Olrog (1979b), Pacheco *et al.* (1996), do Rosário (1996), Saibene *et al.* (1996), Sick (1991, 1993, 1997), Stotz *et al.* (1996), Whitacre (1989).

13. White-naped Swift

Streptoprocne semicollaris

French: Martinet à nuque blanche **Spanish:** Vencejo Nuquiblanco Mexicano
German: Weißbackensegler

Taxonomy. *Acanthylis semicollaris* DeSaussure, 1859, San Joaquín, near Mexico City.

Previously placed in monospecific genus *Semicollum*, largely on the basis of nesting behaviour, but recent research has invalidated this opinion. Alternatively, has at times been linked with *Cypseloides senex* in genus *Aerornis*. Monotypic.

Distribution. W Mexico, in highlands of Chihuahua, Sinaloa, Nayarit, Hidalgo, Morelos and México.

Descriptive notes. 22 cm. Very large swift with heavy body, long broad wings and large square tail, appearing more rounded when fully spread; black-brown with distinct white nape patch. Juvenile probably has pale-fringed plumage and reduced nape patch.

Habitat. Essentially montane, mainly in arid inland regions where recorded to 3600 m. In Mexico at 1500-3000 m, though to sea-level in NW. Main habitats defined as pine-oak forest, tropical deciduous forest and second-

growth scrub. On occasions occurs to sea-level and also in small numbers over coastal slopes of Sierra Madre del Sur. Typically around deep gorges, cliffs and high crags, over forested slopes and brushlands, though also recorded over towns.

Food and Feeding. Upper portion of digestive tract of 1 specimen contained 1072 individual insects: 683 Hymenoptera, 391 Homoptera, 20 Hemiptera, 6 Diptera and 2 Coleoptera. Presence of 681 fire ants (*Solenopsis geminata*) illustrates importance of swarming insects.

Breeding. Eggs present in nests studied in late May. Nests colonially in caves mostly on solid, more or less horizontal, substrates; colonies up to 12 pairs recorded. Nest structure not always employed, with eggs laid in shallow, purpose-built depression, though 26 of 32 nests recently studied were structures mainly of mud with considerable plant material, circular or 40-75% circular truncating towards substrate slope; most nests lined with plant matter. Two eggs; chicks apparently fed only once per day.

Movements. Previously regarded as strictly resident. In Mexico, some withdraw from high cold altitudes in winter, as absent from Distrito Federal, Aug-Mar. Records from outside normal range in Chiapas, S Mexico, and flocks recorded in Apr-May 1993 in Belize suggest some form of dispersal.

Status and Conservation. Not globally threatened. Fairly common to locally common. Apparent break in range between the two main distributional blocks may reflect lack of suitable nesting and/or roosting areas. Regularly recorded at a number of sites, e.g. San Blas (Nayarit), Coajomulco and Cañón de Lobos (Morelos), Temascaltepec (México), Tacámbaro (Michoacan) and Sierra de Atoyac (Guerrero).

Bibliography. Anon. (1998a), Hernández-Baños *et al.* (1995), Howell (1993b), Howell & Webb (1994, 1995a), Land (1970), Mallory (1994), Monroe (1968), Ridgway (1911), Rowley & Orr (1962), Stotz *et al.* (1996), Whitacre (1989, 1992), Wilson & Ceballos-Lascurain (1993).

Subfamily APODINAE

Tribe COLLOCALIINI

Genus *HYDROCHOUS* Brooke, 1970

14. Waterfall Swift

Hydrochous gigas

French: Salangane géante **German:** Riesensalangane **Spanish:** Salangana Gigante
Other common names: Giant Swiftlet

Taxonomy. *Collocalia gigas* Hartert and Butler, 1901, Semangko Pass, Selangor, Malaysia. Genus possibly closest to *Aerodramus*, and these two commonly merged into *Collocalia*; however, large size and differences in breeding biology favour isolation of present species, although some researchers have considered these differences marginal and of doubtful taxonomic significance; other opinions suggest present species may not be closely related to the swiftlet genera. Monotypic.

Distribution. Mountainous areas of Peninsular Malaysia, Sumatra, Borneo and W Java.

Descriptive notes. 16 cm; male 37 g, female 35–39 g. A fairly large swift, appearing rather more like some of the Apodini swifts than the swiftlets, with deeply forked tail; uniformly dark brown above, slightly paler but still very uniform below. Not capable of echolocation.

Habitat. Typically found over mountainous rainforest in areas of waterfalls; known from c. 800 m in Malay Peninsula, c. 440 m in Sumatra and c. 300–1500 m in W Java.

Food and Feeding. Analyses of stomach contents from W Java show prey variable, presumably depending on availability: one stomach contained mainly flying ants, lesser numbers

of Diptera, including sizeable tipulid, a small beetle and a small bug. Others recorded predominance of Diptera. Believed to feed at times on winged termites. Gregarious, often with *Hirundapus giganteus* and to lesser extent *Collocalia linchi* on Java. Though lacks ability to echolocate, has acute poor-light vision and may be mainly a crepuscular feeder. Data suggest this species more likely to be seen foraging during day on Java in rainy season, Oct–Mar.

Breeding. Recorded Oct–Jan in W Java; egg taken late Apr in Malay Peninsula. Nest in latter location of liverworts, collected by birds by pulling with beak while still in flight, and to lesser extent mosses agglutinated with feathers and saliva into truncated cone and attached with same adhesive to rock substrate, on small ledge within spray of waterfall; 90 mm high with depression 12 mm deep × 37 mm wide. Clutch typically 1 egg.

Movements. Believed to be resident, though equivocal. Recorded at night from Fraser's Hill, W Malaysia, and on offshore islands, N Borneo.

Status and Conservation. Not globally threatened. Currently considered near-threatened. Restricted-range species; present in Sumatra and Peninsular Malaysia EBA and Bali Forests EBA. Rare and local, though exact status unclear with few population counts: 60–80 together at well-known breeding site (Gunung-Gede/Pangrango National Park) in W Java, Aug 1985. Counts of up to 8 at site near Gunung Kerinci, in Kerinci-Seblat National Park, SC Sumatra. Said to be common around Mt Pangrango in early 20th century. May be more widespread in Sumatra than currently thought, as 2 records (groups of 7 and 8) from Gunung Leuser and record of 2 from Brestagi. Distribution in Borneo similarly may be more extensive than currently thought. Recorded in Panti Forest Reserve, Johor Province, Malaysia, in Nov 1996.

Bibliography. Genus *COLLOCALIA* G. R. Gray, 1840

15. Glossy Swiftlet

Collocalia esculenta

French: Salangane soyeuse **German:** Glanzkopfsalangane **Spanish:** Salangana Lustrosa
Other common names: White-bellied Swiftlet; Beavan's Swiftlet (*affinis*); Philippine(!)/Grey-rumped(!) Swiftlet (*marginata*)

Taxonomy. *Hirundo esculenta* Linnaeus, 1758. China; error = Ambon.

May be conspecific with *C. linchi*; some authors place race *natalis* in *C. linchi*. Philippine birds commonly split off as a separate allospecies, *C. marginata*, largely on basis of grey rump. Much of variation appears to be clinal. Birds from Halmahera sometimes separated as race *nubila*, but this is

best considered a synonym of *spilura*. Populations on Salayar I and in Tanimbar Is are not currently assigned to any given subspecies; birds from Palawan and Calauit, tentatively placed in *marginata*, may belong to an undescribed race. First six races listed have been considered to form a distinctive western subgroup. Thirty-two subspecies recognized.

Subspecies and Distribution.

- C. e. affinis* Beavan, 1867 - Andaman and Nicobar Is.
- C. e. elachyptera* Oberholser, 1906 - Mergui Archipelago (Myanmar).
- C. e. cyanoptila* Oberholser, 1906 - Malay Peninsula, Sumatra and most of its satellites, and lowland Borneo.
- C. e. vanderbilti* Meyer de Schauensee & Ripley, 1941 - Nias I (off W Sumatra).
- C. e. oberholseri* Stresemann, 1912 - Batu Is and Mentawai Is (off W Sumatra).
- C. e. natalis* Lister, 1889 - Christmas I (Indian Ocean).
- C. e. septentrionalis* Mayr, 1945 - Babuyan, Calayan and N Camiguin Is (N Philippines).
- C. e. isonota* Oberholser, 1906 - N Luzon (N Philippines).
- C. e. marginata* Salvadori, 1882 - C Luzon S to Palawan and Bohol (W & N Philippines).
- C. e. bagobo* Hachisuka, 1930 - Mindoro, Mindanao and Sulu Archipelago (S Philippines).
- C. e. spilura* G. R. Gray, 1866 - N Moluccas.
- C. e. manadensis* Salomonsen, 1983 - N Sulawesi to Sangihe and Talaud Is.
- C. e. esculenta* (Linnaeus, 1758) - C & S Sulawesi through Banggai and Sula Is to C & S Moluccas.
- C. e. minuta* Stresemann, 1925 - Tanahjampea I and Kalao I, in N Flores Sea.
- C. e. sumbawae* Stresemann, 1925 - Sumbawa, Sumba and Flores (W Lesser Sundas).
- C. e. perneglecta* Mayr, 1944 - Sawu, Alor, Wetar, Kisar, Romang and Damar (E Lesser Sundas).
- C. e. neglecta* G. R. Gray, 1866 - Dao, Roti, Semau and Timor (S Lesser Sundas).
- C. e. amethystina* Salomonsen, 1983 - Waigeo I (off NW New Guinea).
- C. e. erwini* Collin & Hartert, 1927 - W New Guinea, c. 1600 m and above.
- C. e. numforensis* Salomonsen, 1983 - Numfor I (in Geelvink Bay, W New Guinea).
- C. e. nitens* Ogilvie-Grant, 1914 - lowland New Guinea, occasionally to 2500 m, and satellite islands.
- C. e. misimae* Salomonsen, 1983 - Louisiade Archipelago.
- C. e. stresemanni* Rothschild & Hartert, 1914 - Admiralty Is (Manus, Rambutyo, Nauna, Los Negros).
- C. e. kalili* Salomonsen, 1983 - New Hanover, New Ireland and nearby Djaul I (C Bismarck Archipelago).
- C. e. spilogaster* Salomonsen, 1983 - Tabar Is (Tatau) and Lihir Group (NE Bismarck Archipelago).
- C. e. hypogrammica* Salomonsen, 1983 - Green Is including Nissan (E Bismarck Archipelago).
- C. e. tametamele* Stresemann, 1921 - New Britain and nearby Witu Is, and Bougainville I (NW Solomons).
- C. e. becki* Mayr, 1931 - C & NE Solomons (including Malaita).
- C. e. makirensis* Mayr, 1931 - Sañ Cristobal I (SE Solomons).
- C. e. desiderata* Mayr, 1931 - Rennell I (S Solomons).
- C. e. uropygialis* G. R. Gray, 1866 - Santa Cruz Is and Vanuatu (including Torres Is and Banks Is).
- C. e. albidior* Salomonsen, 1983 - Loyalty Is and New Caledonia.

Descriptive notes. 9–10 cm; 8–11 g. Tiny, highly polytypic swiftlet with square tail; generally highly blue-glossed above with brown throat, white belly, mottled flanks and dark undertail. Races *stresemanni*, *natalis*, *tametamele*, *desiderata*, *uropygialis*, *marginata* and *septentrionalis* show varying amounts of white on rump; *manadensis* and *spilura* very dark below, effectively lacking whitish belly; races W of line dividing Philippines, Borneo and Sumatra from Sulawesi and Java have plain rectrices, those E generally have white rectrix spots. Species not capable of echolocation.

Habitat. Appears over a variety of habitats, often associated with human habitation. Prefers humid areas to arid ones. In lowland rainforest zone of Papua New Guinea recorded over forest, forest edge and non-forest. In New Guinea noted from sea-level to 4500 m in Carstenz Massif, more typically to 3600 m, and to 1500 m in Sumatra, though more normally in lowlands. Below 400 m in forest interior on Santa Isabel (Solomon Is). In Wallacea found from sea-level to 1200 m on Sangihe, over 1600 m on Flores, over 1000 m on Sumba and at c. 2000 m on Timor over all habitats.

Food and Feeding. In Malaysia mean foraging heights for preferred forested habitat and open country 52.8 m and 68.0 m respectively; 33% of foraging observed within 10 m of vegetation. Same study revealed following dietary percentages: Hymenoptera 55.2% (Formicoidea 29.6%, Apocrita 2.9%, Meliponidae 13.7%), Diptera 2.1% (Acalypterates 1.3%), Coleoptera 34.0%, Isoptera 1.8% and others 6.9%, with mean prey size 4 mm. At Niah feeds for longer periods on tiny stingless bees (Meliponidae) than sympatric congeners. Often forms large loose flocks. Associates readily with other swiftlets, swifts and hirundines. Forages within forest if aspect open enough. On Sangihe possible niche separation noted, this species often feeding between trees beneath canopy level while *Aerodramus infuscatus* feeds above canopy.

Breeding. Season mainly Feb–Mar Andaman and Nicobar Is. Egg-laying Mar–Aug, peaking Apr, in protracted breeding season, Kuala Lumpur, peninsular Malaysia; also Selangor Feb–Nov, Sumatra Mar and Jun, Flores Mar–Sept, Sumbawa Apr–May, Sumba May, S Sulawesi Nov, Buru Sept, Vanuatu Jun–Feb. Young almost fledged late Sept, Taliabu, Sula Is. Nests in Philippines as follows: Sibuyan Jun, N Luzon and Panay May, Negros May and Sept, and Mindanao Apr–May. In New Guinea breeds apparently in both wet and dry seasons, probably peaking in latter. At Niah, Sarawak, egg-laying occurs in 3 seasons annually: Mar–Apr, mid-Jun to mid-Jul and Oct–Nov, well synchronized both between and within small groups of nests. Nests singly or in colonies, often vast. Nest in New Guinea cup of moss, rootlets, lichens and other vegetable matter attached by saliva to vertical or very steep surface; on Andaman Is shallow, flat-bottomed half-cups 70 mm × 50 mm externally with central depression 20 mm deep, entirely of vegetable matter, attached bracket-like to substrate with brownish saliva. Wide variety of sites including buildings, shallow caves, mouths of large caves, dense overhanging rocks, holes in rocks, hollow trees, among roots of large trees; sometimes dense nest clusters formed; all sites well lit due to lack of echolocation ability; nest-building takes 19–36 days. Two eggs typical, particularly in *cyanoptila*; interval between eggs 2 days; both sexes brood; incubation period 19–24 days, mean 21.5 days. Fledging period varies: where both

On following pages: 16. Linchi Swiftlet (*Collocalia linchi*); 17. Pygmy Swiftlet (*Collocalia troglodytes*); 18. Seychelles Swiftlet (*Aerodramus elaphrus*); 19. Mascarene Swiftlet (*Aerodramus francicus*); 20. Indian Swiftlet (*Aerodramus unicolor*); 21. Philippine Swiftlet (*Aerodramus mearnsi*); 22. Moluccan Swiftlet (*Aerodramus infuscatus*); 23. Mountain Swiftlet (*Aerodramus hirundinaceus*); 24. White-rumped Swiftlet (*Aerodramus spodiopygius*); 25. Australian Swiftlet (*Aerodramus terraereginae*); 26. Himalayan Swiftlet (*Aerodramus brevirostris*).

young survive, 34-50 days, mean 42 days; where both hatch but only 1 survives, 31-46 days, mean 38.5 days; and where only 1 hatches, 28-44 days, mean 36 days; young fed several times daily. Average breeding success 57% with 1-1 young fledged per breeding effort.

Movements. Resident. Australian record as likely to represent undiscovered population as to imply dispersal or vagrancy, though this view not universally supported and there are a number of records from islands in Torres Strait. Recorded only outside breeding season in S Brunei.

Status and Conservation. Not globally threatened. Often abundant, though tends to be scarce or even absent in arid areas of New Guinea. Common in many parts of Sumatra; uncommon in some areas of W New Britain and Solomon Is; common throughout Vanuatu. Malaysian colony at Ampang Reservoir near Kuala Lumpur had c. 10,000 pairs in 1978/79. In Nicobar Is, species is apparently increasing at expense of *Aerodramus fuciphagus*, which is declining as result of overharvesting. Occurs in many protected areas throughout extensive range, e.g. Mount Kinabalu National Park (Borneo) and Gunung-Gede/Pangrango National Park (Java).

16. Linchi Swiftlet

Collocalia linchi

French: Salangane linchi **German:** Linchisalangane **Spanish:** Salangana Linchi
Other common names: Cave Swiftlet

Taxonomy. *Collocalia linchi* Horsfield and F. Moore, 1854, Java.

May be conspecific with *C. esculenta*; some authors place race *C. e. natalis* in present species. Older synonym for species, *C. fucivora* (Streubel, 1848), is a forgotten name. Four subspecies recognized.

Subspecies and Distribution.

C. l. ripleyi Somadikarta, 1986 - N & S Bukit Barisan, Sumatra.

C. l. dodgei Richmond, 1905 - Mt Kinabalu (Sabah).

C. l. linchi Horsfield & F. Moore, 1854 - Madura, Bawean and Nusa Penida Is and Java.

C. l. dedii Somadikarta, 1986 - Bali and Lombok.

Descriptive notes. 10 cm. A tiny swiftlet with a square tail; plumage very similar to that of *C. esculenta* but green-glossed and lacks rectrix spots; in the hand, differs from *C. esculenta* by absence of feather tuft on hind toe, though this feature and perhaps even plumage gloss seem equivocal. Race *dodgei* has shorter wings and tail; *ripleyi* considerably shorter tail and more pronounced dark shafts to abdomen feathers; *dedii* longer wings and tail, with darker plumage. Species not capable of echolocation.

Habitat. Occurs from sea-level up into highlands, over both forest and open country. In Sumatra and Borneo, occurs only at high altitude. On Lombok recorded from sea-level up to over 500 m.

Food and Feeding. Gregarious. Will forage in crowns of emergent trees, particularly fruiting figs.

Breeding. Self-supporting bracket-shaped nest consisting of thin pieces of vegetable matter, species used depending on availability. Two white elongate eggs.

Movements. Resident.

Status and Conservation. Not globally threatened. Believed to be extinct on Malay Peninsula. Apparently rarest in Sumatra. Race *dodgei* seen in good numbers on Mt Kinabalu in 1988. Common on Java and satellite islands. Practice reported from Java of converting house-based colonies of this species into colonies of *Aerodramus fuciphagus* to profit from edible-nest harvest will reduce number of colonies.

Bibliography. Andrew (1985), Clayton *et al.* (1996), Coates & Bishop (1997), Duckworth & Kelsh (1988), Hellebrekers & Hoogerwerf (1967), Inskipp *et al.* (1996), Junge (1936), Lee *et al.* (1996), MacKinnon (1988), MacKinnon & Philipps (1993), van Marle & Voous (1988), Mason (1989), Medway (1962d, 1966), Medway & Pye (1977), Meyer de Schauensee & Ripley (1940), Peters (1940b), Richmond (1905), Salomonsen (1983), Smythies (1981), Somadikarta (1982, 1986), Spennemann (1928), White & Bruce (1986).

17. Pygmy Swiftlet

Collocalia troglodytes

French: Salangane pygmée **German:** Zwergsalangane **Spanish:** Salangana Chica

Taxonomy. *Collocalia* [sic] *troglodytes* G. R. Gray and Mitchell, 1845, Philippines. Monotypic.

Distribution. Philippines including Palawan, but not Sulu Archipelago.

Descriptive notes. 9 cm. Tiny swiftlet with square tail; black upperparts with neat, well-defined white rump band; mottled underparts with brown throat, whitish belly and dark undertail-coverts. From Philippine races *marginata* and *septentrionalis* of *C. esculenta* by pure white, not mottled, grey-white band. Uncertain whether or not species is capable of echolocation.

Habitat. A lowland species, most frequently encountered over forest and inland water.

Food and Feeding. Typically forages in small groups.

Breeding. Season on Mindanao, May and Jul; on Bohol, Apr; Negros, Apr; Luzon, young in nest in Sept. Half-cupped, self-supporting, bracket-shaped nest of vegetable matter bound with hard, white, translucent saliva; edibility uncertain.

Movements. Resident.

Status and Conservation. Not globally threatened. Fairly common to common. Recently recorded as common in Rajah Sikatuna National Park, Bohol. Commonly represented in collections of swiftlets taken from Philippines over many decades.

Bibliography. Brooks, Dutton *et al.* (1996), Brooks, Magsalay *et al.* (1995), Danielsen *et al.* (1994), Delacour & Mayr (1946), Dickinson (1989b), Dickinson, Kennedy & Parkes (1991), Dickinson, Kennedy, Read & Rozendaal (1989), Evans, Dutton & Brooks (1993), Gogorza y González (1987), Kutter (1982), Lee *et al.* (1996), Manuel (1937), McGregor (1903, 1906, 1907b, 1909), Medway (1966), Medway & Pye (1977), Meyer de Schauensee & duPont (1962), Oberholser (1906), duPont (1971), duPont & Rabor (1973b), Rabor (1938b, 1954, 1977), Rand & Rabor (1960), Salomonsen (1983).

Genus AERODRAMUS^o Oberholser, 1906

18. Seychelles Swiftlet

Aerodramus elaphrus

French: Salangane des Seychelles **German:** Seychellensalangane **Spanish:** Salangana de Seychelles
Other common names: Seychelles Cave Swiftlet

Taxonomy. *Collocalia fuciphaga elaphra* Oberholser, 1906, Mahé Island, Seychelles.

Genus often merged into *Collocalia*. Forms superspecies with *A. francicus*, and sometimes considered conspecific. Monotypic.

Distribution. La Digue, Mahé and Praslin, Seychelles. Formerly occurred on Felicite.

Descriptive notes. 11 cm; 10.5 g. Small swiftlet with forked tail; brown upperparts with rump marginally paler, underparts paler mid-brown. In hand has copious white rami of back feathers, and longer wings and larger bill than *A. francicus*. Available information suggests species probably capable of echolocation.

Habitat. Occurs over wide variety of habitats, including forest and wetlands, from lowlands up into highlands.

Food and Feeding. Flying ants predominated in a study of food brought in to young. Species is gregarious, foraging over various types of habitat.

Breeding. May breed throughout year, and certainly extended as colonies visited early Jul 1970 contained eggs and young of various ages; season initially thought to relate to SE monsoon from Jun to Nov. Nests in caves, at 1 site created by a number of huge granite boulders in a valley where 2 colonies of 14 and 23 nests in 1970. Bracket-shaped, self-supporting nest of grey-green lichen strands agglutinated with saliva, strong, yet dry and flexible; nest hinge dark brown with large quantity of saliva; nest 55 mm high × 105 mm wide, with depression 35 mm front to back. One egg typical. Replacement clutches and fresh clutches after successful fledging within 14 days; incubation period 25-30 days; fledging period 42 days.

Movements. Resident. Recorded as a wanderer to Aride.

Status and Conservation. VULNERABLE. Restricted-range species; present in Granitic Seychelles EBA. Lack of additional suitable sites may limit both population and distribution. Disturbance and vandalism have caused concern, and fitting of metal grilles across cave entrances has been recommended. Vulnerable also to alien predators, especially cats and Common Barn-owls (*Tyto alba*). Recent increase on La Digue may be due to changed hydrological conditions or immigration from former colony on Felicite. Overall population believed to number 2500-3000 birds. Mahé population estimated at 2263 (±371) individuals using capture-recapture technique in Mar 1997, while La Gogue colony estimated at 500-600 nests in Jan 1996. It is likely, especially in Morne Seychelles National Park, that undiscovered cave colonies exist. Only known Praslin population is Mt Cabris colony where there were 79 nests in Apr 1997; cave of colony at L'Amitié has been destroyed, and colony believed to be at Fond d'Azore cannot be located. Two colonies above La Réunion had 35-45 nests in 1997.

Bibliography. Benson (1967b), Bullock (1990), Clayton *et al.* (1996), Collar & Andrew (1988), Collar & Stuart (1985), Collar *et al.* (1994), Diamond & Fearn (1980), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Evans (1977), Gaymer *et al.* (1969), Gerlach (1997), Lee *et al.* (1996), Loustau-Lalanne (1962), MacDonald (1978), Medway (1966), Mountfort (1988), Newton (1867), Oberholser (1906), Penny (1974), Pratt (1986), Procter (1970, 1972), Rocamora (1997), Rocamora & Skerrett (1999), Sinclair & Langrand (1998), Stattersfield *et al.* (1998), Vesey-Fitzgerald (1936), Watson, G.E. *et al.* (1963), Watson, J. (1979, 1984).

19. Mascarene Swiftlet

Aerodramus francicus

French: Salangane des Mascareignes **German:** Mauritius-salangane **Spanish:** Salangana de las Mascareñas
Other common names: Grey-rumped(!) Indian Ocean/Mascarene Cave/Mauritius Swiftlet

Taxonomy. *Hirundo francica* J. F. Gmelin, 1789, Mauritius.

Genus often merged into *Collocalia*. Forms superspecies with *A. elaphrus*, and sometimes considered conspecific; has alternatively been lumped with *A. fuciphagus*, although the two do not appear to be closely related. In past, was treated as part of a composite species also including *A. infuscatus*,

A. hirundinaceus, *A. spodiopygius* and *A. terraereginae*. Differences between birds on Reunion and Mauritius suggest that two subspecies may be involved. Monotypic.

Distribution. Mauritius and Reunion (Mascarenes).

Descriptive notes. 10.5 cm; 9.9-5 g. Small swiftlet with forked tail; dark brown upperparts with whitish rump clearly paler, pale brown underparts. Species capable of echolocation.

Habitat. Occurs over wide range of habitats. Nesting caves are typically sited in lava tunnels.

Food and Feeding. Gregarious, foraging in flocks. Usually feeds at least 20 m above ground, though will feed lower over lakes and during cloudy periods. In 2 boluses of prey collected by adults to feed nestlings. Diptera predominated; most prey 1.6-3.2 mm long, though some flying ants 5.2-8.2 mm with an

anthomyid fly measuring 4-2 mm. Foraging ends never more than 35 minutes after dark and more typically within 30 minutes.

Breeding. Season not clearly defined with eggs and young present in every month except Apr and May 1974 in a 16-month study of 2 colonies from Oct 1973 to Jan 1975, and even during these months nests were being built; these 2 sites, though close, were not in synchrony. Openings of subterranean waterways typically used for breeding, often sited in canefields. Self-supporting, bracket-shaped nest of lichen filaments agglutinated with saliva which is copious only in hinge; mean 62.5 mm x 55 mm and 30 mm deep. Two eggs typical, 1 rarely; 4 weeks from starting fresh nest to laying, or 4-6 weeks if nest destroyed, though slower if starting again after a non-breeding period; mean relaying interval 27 days; interval between clutches c. 3 weeks, allowing for 2 broods in 6-5 months or 3 in 9-5 months. Incubation period probably 21-23 days; mean fledging period probably 45-55 days. Hatching success high, 84% in non-vandalized nests, but 24 of 44 nests destroyed by vandals.

Movements. Resident. Records from Madagascar no longer considered acceptable.

Status and Conservation. Not globally threatened. Currently considered near-threatened. Restricted-range species: present in Reunion EBA and Mauritius EBA. Population limited by paucity of suitable nest-sites. Generally rather common to locally abundant on Reunion and Mauritius. On Reunion several colonies threatened by actions of speleologists, while many cave sites inaccessible which, though granting protection, limits estimation of population size.

Bibliography. Barré (1983, 1988), Barré *et al.* (1996), Berlioz (1946), Cheke (1987b, 1987c), Cheke & Jones (1987), Clayton *et al.* (1996), Collar *et al.* (1994), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Gill (1971), Horne (1987), Langrand (1995), Langrand & Sinclair (1994), Lee *et al.* (1996), Mayr (1937a), Medway (1966), Medway & Pye (1977), Michel (1992), Milon (1951), Oberholser (1906), Pratt (1986), Procter (1972), Rand (1936), Rountree *et al.* (1952), Sargeant (1992b), Sims (1961), Sinclair & Langrand (1998), Stattersfield *et al.* (1998), Staub (1973, 1976), Stresemann (1925).

20. Indian Swiftlet

Aerodramus unicolor

French: Salangane de Malabar **German:** Malabarsalangane **Spanish:** Salangana de Malabar
Other common names: Indian Edible-nest Swiftlet(!)/Swift

Taxonomy. *Hirundo unicolor* Jerdon, 1840, Coonoor Pass.

Genus often merged into *Collocalia*. Previously considered conspecific at various times with *A. brevirostris* or *A. fuciphagus*; has also been associated with *A. francicus* and *A. elaphrus*, due mainly to relative geographical proximity; probably closest to *A. vanikorensis* group. *A. brevirostris rogersi* has been tentatively linked with present species on morphological grounds. Monotypic.

Distribution. SW India, from S Maharashtra S through Western Ghats to Kerala and W Tamil Nadu, and throughout Sri Lanka.

Descriptive notes. 12 cm. Medium-sized swiftlet with shallow tail-fork; dark brown upperparts with uniform or marginally paler rump; uniformly pale brown underparts and unfeathered tarsi. In hand from *A. brevirostris* by smaller size (very little overlap), less glossy and slightly paler upperparts. Species capable of echolocation.

Habitat. From lowlands, wherever there are rocky hills with suitable nesting caves, to 2200 m over a variety of habitats, though on Sri Lanka primarily an upland species. Occurs over scrub and dry deciduous forest at Mudumalai Wildlife Sanctuary, India. Fre-

quents small rocky offshore islands as well as mainland habitats.

Food and Feeding. Diptera, Hemiptera and Hymenoptera predominate with Coleoptera, Odonata and Trichoptera also recorded. Two jassid mango-hoppers, *Ideocerus niveosparus* and *I. atkinsoni*, presumably taken over nearby mango orchards, accounted for 80% of 4 stomach contents examined. On Sri Lanka recorded taking prey from around lights at night; nestlings were fed well into night.

Breeding. Season mainly Mar-Jun, S India; nest-building late Dec to early Jan with second brood, if harvesting has not occurred, in Aug-Sept, Sri Lanka. Nests colonially in caves, including sea-caves, railway tunnels, etc. Self-supporting, bracket-shaped nest, 65-80 mm wide x 20-25 mm deep, with sparse to moderate plant content and often feathers, agglutinated with firm, whitish saliva; hinge and some whole nests made almost entirely of saliva, imparting "edible" qualities; nests often infested with bed bugs (*Cimex rotundatus*); large numbers of nests often densely clustered. Two eggs; double-brooded Sri Lanka; young cling to outside of nest when half-grown.

Movements. Believed resident, though probably occasional winter visitor to Maldives.

Status and Conservation. Not globally threatened. Particularly abundant in Sri Lanka, where is one of most abundant of mountain bird species; also abundant in cave systems of Western Ghats, and on islands off Malabar coast. Colony at Venguria, Western Ghats, in 1940's contained c. 5000 birds. Present in several protected areas, e.g. Mudumalai National Park (SW India) and Ingiriya Forest Reserve (Sri Lanka). In Sri Lanka illegal nest harvesting has resumed since 1993, with collection noted in Central, Uva and Sabaragamuwa Provinces, despite protection by law; although short time since resumption of this activity makes assessment of population trends difficult, it has

been noted that no young have fledged in surveyed caves from which collection has taken place and that some caves appear to have been abandoned completely.

Bibliography. Abdullali (1942), Aitken (1895), Ali (1996), Ali & Ripley (1983), Chakravarthy & Purna Chandra Tejasvi (1992), Daniels (1997), Foulkes (1904), Gokula & Vijayan (1997), Grewal (1995), Grimmett *et al.* (1998), Gunawardana (1997), Henry (1998), Inskipp *et al.* (1996), Kannan (1998), Lamsfuss (1998), Medway (1966), Medway & Pye (1977), Novick (1959), Oates (1890), Oberholser (1906), Phillips (1963, 1978), Pratt (1986), Procter (1972), Ripley (1964b, 1982), Whistler (1936).

21. Philippine Swiftlet

Aerodramus mearnsi

French: Salangane de Mearns **German:** Braunbüzelsalangane **Spanish:** Salangana Filipina
Other common names: Philippine Grey Swiftlet, Brown-rumped Swiftlet(!)

Taxonomy. *Collocalia fuciphaga mearnsi* Oberholser, 1912, Hights in the Oaks, near Pauai, Benguet, Luzon.

Genus often merged into *Collocalia*. Forms superspecies with *A. infuscatus*, *A. hirundinaceus*, *A. spodiopygius* and *A. terraereginae*. Previously placed in the *A. vanikorensis* superspecies. Monotypic.

Distribution. Philippines, on Luzon, Mindoro, Palawan, Negros, Bohol and Mindanao.

Descriptive notes. 10-10.5 cm. Small swiftlet with shallow tail-fork; dark brown upperparts with uniform rump; paler mid-brown underparts. In hand from slightly smaller, sympatric *A. vanikorensis amelis* by tarsus feathering, smaller, more decurved bill, less forked tail, and white tips to rami of rump feathers. No information available as to whether or not species is capable of echolocation.

Habitat. Primarily a submontane species. Recorded breeding at 1600 m on Mt Halcon, Mindoro, and at 700 m on Bohol.

Food and Feeding. Unknown, but should resemble that of other *spodiopygius* group members.

Breeding. Nests originally thought to belong to *A. vanikorensis amelis* 700 m inside Miatan Caves, Mindanao, in May 1952 were shallow saucers placed in rock cavities and are now believed to have been nests of *A. mearnsi*. Nests consist of moss held together with saliva which does not remain moist but hardens. Breeds May on Mindoro. Four eggs.

Movements. Resident.

Status and Conservation. Not globally threatened. Uncommon. Recently recorded as rare in Rajah Sikatuna National Park, Bohol; also present in Mount Canlaon National Park (Negros) and Mount Katanglad National Park (Mindanao). Problems of identification render estimations of true status difficult; however, scarcity of museum specimens suggests that species may well be genuinely uncommon.

Bibliography. Brooks & Dutton (1997), Brooks, Dutton *et al.* (1996), Brooks, Evans *et al.* (1992), Brooks, Magsalayan *et al.* (1995), Danielsen *et al.* (1994), Dickinson (1989a), Dickinson *et al.* (1991), Dutton *et al.* (1992), Evans, Dutton & Brooks (1993), Gilliard (1950a), Inskipp *et al.* (1996), Oberholser (1912), duPont (1971), Ripley & Rahor (1958).

22. Moluccan Swiftlet

Aerodramus infuscatus

French: Salangane des Moluques **German:** Molukksalangane **Spanish:** Salangana Moluqueña

Taxonomy. *Collocalia infuscata* Salvadori, 1880, Ternate.

Genus often merged into *Collocalia*. Forms superspecies with *A. mearnsi*, *A. hirundinaceus*, *A. spodiopygius* and *A. terraereginae*. Previously placed in composite species *A. francicus* or alternatively in *A. vanikorensis*; considered conspecific with *A. spodiopygius* by some authors. Three subspecies recognized.

Subspecies and Distribution.

A. i. sororum (Stresemann, 1931) - Sulawesi.

A. i. infuscatus (Salvadori, 1880) - N Moluccas (Ternate, Halmahera and Morotai, and possibly Bacan and Obi), and recently recorded on Sangihe and Siau.

A. i. ceramensis (van Oort, 1911) - S Moluccas (Buru, Boano, Ambon and Seram).

Recently recorded in Sula Is (Taliabu), but racial identity unknown.

Descriptive notes. 10 cm. Small swiftlet with forked tail and broad wings with slightly bulging secondaries; upperparts black-brown with rump uniform or slightly paler and greyish; underparts pale brown. Race *sorum* has broader, distinct, grey-white rump band, 6-7 mm, and silvery grey underparts with brownish throat; *ceramensis* has broadest and whitest rump band, 10-12 mm. Differs from sympatric races of *A. vanikorensis*, notably *waigeuensis*, by greater tendency towards tarsal feathering (care required, as equivocal), paler underparts and extensively white rami on rump feathers. No information available as

to whether or not species is capable of echolocation.

Habitat. Generally appears to occur at higher altitude than closest sympatric congener, though collected on Sulawesi at 50-2500 m, on Seram at c. 700 m, on Sangihe from sea-level to 1200 m, and on Buru to 750 m.

Food and Feeding. On Sangihe possible niche separation noted, this species often feeding above canopy while *Collocalia esculenta* fed between trees beneath canopy level.

Breeding. Thought to make a nest consisting of vegetable matter and attached to cave wall.

Movements. Resident. May be nomadic.

Status and Conservation. Not globally threatened. Not uncommon on Seram at 700 m; common on Sangihe, though less so at lower altitudes, and especially common at higher altitudes on Gunung Awu. Present in Dumoga-Bone and Lore Lindu National Parks (Sulawesi) and Manusela National Park (Seram).

Bibliography. Bowler & Taylor (1989), Browning (1993), Coates & Bishop (1997), Inskipp *et al.* (1996), Isherwood *et al.* (1997), Jepson (1993), Lambert (1994), Mayr (1937a), Pratt (1986), Riley (1997a), Rozendaal & Dekker (1989), Salomonsen (1983), Stones, Lucking *et al.* (1997), Stresemann (1914a, 1932, 1940), Wardill (1995), Watling (1983), White & Bruce (1986).

23. Mountain Swiftlet

Aerodramus hirundinaceus

French: Salangane de montagne German: Bergsalangane Spanish: Salangana Montana

Taxonomy. *Collocalia fuciphaga hirundinacea* Stresemann, 1914, Upper Utakwa River, New Guinea. Genus often merged into *Collocalia*. Forms superspecies with *A. mearnsi*, *A. infuscatus*, *A. spodiopygius* and *A. terraereginae*. Previously placed in composite species *A. francicus* or alternatively in *A. vanikorensis*; considered conspecific with *A. spodiopygius* by some authors. Three subspecies recognized.

Subspecies and Distribution.

A. h. baru (Stresemann & Paludan, 1932) - Yapen I (in Geelvink Bay, NW New Guinea).
A. h. excelsus (Ogilvie-Grant, 1914) - over 1600 m in Snow Mts and Carstenz peaks, Irian Jaya.
A. h. hirundinaceus (Stresemann, 1914) - much of New Guinea.

Descriptive notes. 11-13 cm. A medium-sized swiftlet with a moderately forked tail; uniform dark brown upperparts, some birds with a suggestion of a paler rump; underparts pale grey to mid-grey, though mid-throat can be dark. Differs from sympatric *A. vanikorensis* by feathered tarsi, tiny, more decurved bill, greater white in rami of back, darker, more blue-glossed upperparts and clearly paler underparts. Race *baru* has very dark upperparts, browner underparts and heavy tarsal feathering; *excelsus* much larger than nominate. Species capable of echolocation.

Habitat. Occurs over wide range of habitats, mainly in highlands, where recorded to 4000 m. Relatively low numbers can be encountered in lowlands where there are adjacent hills.

Food and Feeding. Gregarious, commonly foraging in association with other swifts.

Breeding. Active colony noted late Sept. Tari District, Southern Highlands Province; birds entering possible nest-site in Jun on Karkar I. Colonial breeder. Externally supported nest is bulky structure of mosses, filmy ferns, grasses and rootlets bound to central core, sited in dimly lit or completely dark situations; in some high-altitude breeding caves nests can be sited on floor, presumably because their main predators there, snakes, are infrequent above 1000 m. Little or no saliva used for agglutination or attachment to narrow rock ledge or niche. One egg.

Movements. Nomadic movements may account for occasional absence of the species from some parts of range.

Status and Conservation. Not globally threatened. Generally scarce in lowlands, locally common to abundant in highlands. Commonly represented in collections of swiftlets from New Guinea over many decades.

Bibliography. Beechler (1978), Beechler *et al.* (1986), Bravery (1972), Clapp (1986, 1987), Clayton *et al.* (1996), Coates (1985), Diamond (1972), Fenton (1975), Gilliard & LeCroy (1961), Gregory (1995a, 1995b), Hadden (1975), Mackay (1991), Mayr (1937a), Mayr & Rand (1937), Medway (1966), Medway & Pye (1977), Murray (1988), Pratt (1986), Rand (1942a), Rand & Gilliard (1967), Ripley (1964a), Salomonsen (1983), Schodde & McKean (1972), Stresemann & Paludan (1932), Tarburton (1990b).

24. White-rumped Swiftlet

Aerodramus spodiopygius

French: Salangane à croupion blanc German: Weißbürtzelsalangane Spanish: Salangana Culiblanca

Other common names: Grey(!)/Grey-rumped(!) Swiftlet, Pacific White-rumped Swiftlet

Taxonomy. *Macropteryx spodiopygius* Peale, 1848, Upolu and Tutuila, Samoa Islands.

Genus often merged into *Collocalia*. Forms superspecies with *A. mearnsi*, *A. infuscatus*, *A. hirundinaceus* and *A. terraereginae*, and last three have all been considered conspecific with present species. *A. sawiellii* may prove to be merely a race of present species. Previously placed in composite species *A. francicus*. Eleven subspecies recognized.

Subspecies and Distribution.

A. s. delichon (Salomonsen, 1983) - Admiralty Is.
A. s. eichhorni (Hartert, 1924) - Mussau I in St Matthias Group (NC Bismarck Archipelago).
A. s. noonaedanae (Salomonsen, 1983) - New Ireland and New Britain.
A. s. reichenowi (Stresemann, 1912) - S & E Solomon Is.
A. s. desolatus (Salomonsen, 1983) - Duff Is, Swallow Is and Santa Cruz Is.
A. s. epiensis (Salomonsen, 1983) - N & C Vanuatu.
A. s. ingens (Salomonsen, 1983) - S Vanuatu.
A. s. leucopygius (Wallace, 1864) - Loyalty Is and New Caledonia.
A. s. assimilis (Stresemann, 1912) - Fiji.
A. s. townsendi (Oberholser, 1906) - Tonga.
A. s. spodiopygius (Peale, 1848) - Samoa.

Descriptive notes. 10-11.5 cm; one female 8 g. A small to medium-sized swiftlet with a deep tail-fork; highly polytypic. Rump pale throughout, but degree of paleness varies geographically. Most races are much paler below than *A. vanikorensis*, practically pure white in the case of *leucopygius*, although throat is often rather dark; races *townsendi*, *desolatus* and *epiensis* are sooty below. Degree of tarsal feathering is variable both within and especially among races; heavily feathered in *epiensis* and *ingens*, though unfeathered or only lightly feathered in most other races; in *ingens*, dark brown face shows greater contrast with pale underparts. Species capable of echolocation.

Habitat. Occurs over wide range of island habitats, from lowlands to highlands, on New Britain to 1890 m and on Bougainville to 1600 m. On Santa Isabel occurs above 700 m over montane forest.

Food and Feeding. Race *assimilis* of Fiji compared with *A. terraereginae chillagoensis* of Australia: present species takes smaller prey in smaller boluses, containing more individuals; 32 boluses

of present species contained 167 species of invertebrate, whereas 32 boluses of *A. terraereginae* contained 303 species, averaging 10 species more per bolus than in present species. Can be encountered foraging in large groups, alone or with sympatric congeners. Forages over a range of elevations.

Breeding. Season on Vanuatu Oct-Feb; active colony reported on Lou I (S of Manus in Admiralty Is), Mar; on Fiji first eggs laid Sept-Oct, most chicks fledging Jan, but replacement clutches extend season into Feb, sometimes Mar. Colonial. Nests in caves, including sea-caves, or similar situations, including man-made structures, but also below overhanging rocks in gulleys or under fallen trees; mainland sites are used, as well as island ones. Substantial self-supporting, bracket-shaped nest with shallow central depression, consisting of fine vegetable matter; on Fiji lichens, liverworts, filmy ferns and mosses predominate, though grasses used extensively at 1 site, agglutinated with firm saliva and attached to cave walls; nests sometimes cylinder-shaped where birds add to them each time they breed. On Fiji nests of *assimilis* typically closely bunched, though sometimes 1-2 m apart and exceptionally 70 m, often attached not to wall but to other nests; measure 50 × 50 × 21 mm, mean volume index 52.5 cm³. Clutch of 1 or 2 white eggs, though mean of 57 clutches 1-98; laying interval 3-5 days, mean 4; incubation period 22-25 days, shared by both parents who also brood at night; lost clutches and even lost broods typically replaced within 9-14 days; evidence suggests that sometimes more than 1 female lays eggs in same nest. Second chick hatches within 1-5 days of first; nestling period 45-46 days; daily feeding rate 2-8 visits. Average breeding success 53%, with 1-1 young fledged per breeding effort.

Movements. Resident. Vagrant to New Zealand.

Status and Conservation. Not globally threatened. Fairly common to abundant over much of range; 8 colonies in Fiji contained over 1400 nests in 1975 and 1976. Commonest swiftlet in W New Britain. However, decline noted in some parts of range, e.g. by 1960's *epiensis* occurred, uncommonly, only on Malo I and W coastal Espiritu Santo I in Vanuatu. Local and uncommon on Santa Isabel, Solomon Is.

Bibliography. Banks (1984), Bregulla (1992), Cain & Galbraith (1956), Clayton *et al.* (1996), Clunie (1984), Coates (1985), Engbring & Ramsey (1989), Finch & McKean (1987), Hadden (1981), Hannecart & Léocart (1980), Hicks (1992a), Holyoak (1979), LeCroy & Peckover (1983), Lee *et al.* (1996), Mayr (1945), Medway (1966), Medway & Pye (1977), Muse & Muse (1982), Pratt (1986), Pratt *et al.* (1987), Reed (1980), Rinke (1987), Salomonsen (1983), Stresemann (1912, 1926), Stresemann & Paludan (1932), Suthers & Hector (1982), Tarburton (1986a, 1986b, 1986c, 1987a, 1987b, 1988a, 1988b, 1990b, 1993a, 1993b), Tarburton & Minot (1987), Vuilleumier & Gochfeld (1976), Watling (1982), Webb (1992).

25. Australian Swiftlet

Aerodramus terraereginae

French: Salangane d'Australie German: Queenslandsalangane Spanish: Salangana Australiana Other common names: Grey Swiftlet(!)

Taxonomy. *Cypselus terra-reginae* E. P. Ramsay, 1875, north-east coast ranges, near Cardwell, Queensland.

Genus often merged into *Collocalia*. Forms superspecies with *A. mearnsi*, *A. infuscatus*, *A. hirundinaceus* and *A. spodiopygius*. Previously placed in composite species *A. francicus* or alternatively in *A. vanikorensis*; considered conspecific with *A. spodiopygius* by some authors. Race *chillagoensis* has even been treated as a separate species, although solid grounds for such a split would appear to be lacking. Two subspecies recognized.

Subspecies and Distribution.

A. t. terraereginae (E. P. Ramsay, 1875) - coastal N Queensland.
A. t. chillagoensis Pecotich, 1982 - Chillagoe, Mitchell and Palmer districts, inland Queensland.

Descriptive notes. 11 cm; 9.5 g. Medium-sized swiftlet with shallowly forked tail; dark brown upperparts with typically paler rump; though some birds uniform across upperparts; pale grey-brown underparts; tarsi heavily feathered and tail proportionally long for *A. spodiopygius* group. Race *chillagoensis* is smaller and paler. Species capable of echolocation.

Habitat. Recorded to 1000 m, generally below 500 m. Much foraging over dry savanna-type terrain, though also seen feeding at rainforest margin. Breeds in both island and mainland sites.

Food and Feeding. Habits of race *chillagoensis* compared with those of *A. spodiopygius assimilis* of Fiji: present species takes larger prey in larger boluses, containing fewer individuals; 32 boluses contained 303 invertebrate species, averaging 10 species more per bolus than in *A. spodiopygius*; 32 boluses of latter contained only 167 species. Large numbers of present species leave nest cave at regular intervals during day to feed locally; after c. 30 minutes they return to cave for 10 minutes of lesser activity. Feeds less than 30 km from breeding sites.

Breeding. At Tully Gorge, North Queensland, 95% of nests contained eggs or nestlings at various stages of development, early Oct to mid-Jan; breeds at Chillagoe, Oct-Mar. Colonial, averaging 77 nests Chillagoe. Nesting caves totally dark or with little twilight; nests 2-20 m above cave floor on smoothly concave walls, though extrusions or cracks readily utilized; at 1 large colony average distance between nests 8 cm. At Chillagoe kangaroo grass (*Themeda australis*) and black spear grass (*Heteropogon contortus*) commonest nesting materials; 1 nest made of *Casuarina* twigs agglutinated with laminae of firm translucent saliva. Shallower nests than those of *A. spodiopygius*: nest of nominate race 56 × 45.5 × 3 mm, mean volume index 7.5 cm³; *chillagoensis* 49 × 42.5 × 12 mm, mean 25 cm³. One egg, laying apparently stimulated by rain; mean incubation 26.5 days, both sexes incubating; lost clutches and broods less than 10 days old replaced within 6-18 days. Nestling period 46 days in good season, 51 in poor season. Second clutch also of 1 egg laid 50 days after first, uses heat from first nestling to aid incubation. Feeding rates 5 per day in good season, 2 per day in bad season.

Movements. Resident.

Status and Conservation. Not globally threatened. Common in lowlands. Survey of 34 active colonies during 1985-1987 showed peak count of 500 pairs for a single colony. Range appears stable but diminished numbers of breeding birds recorded at several colonies. It has been suggested that frequency of sightings away from areas with colonies implies new colonies will be found.

Bibliography. Blakers *et al.* (1984), Busst (1956), Cassels (1961), Clayton *et al.* (1996), Coles *et al.* (1987), Crouther (1983a, 1983b), Griffin (1969), Higgins (1999), Lee *et al.* (1996), Lindsey (1992), Macdonald (1988), Medway (1966), Medway & Pye (1977), Pecotich (1974), Pecotich & Collins (1966), Pizzey & Doyle (1998), Pratt (1986), Salomonsen (1983), Schodde & Tidemann (1986), Schulz (1991), Seton (1965), Simpson & Day (1998),

Smyth (1976, 1980), Smyth *et al.* (1980), Storr (1984), Strahan (1994), Stresemann & Paludan (1932), Tarburton (1988a, 1988b, 1993b), Tarburton & Minot (1987), Trounson & Trounson (1987), Wheeler (1959).

26. Himalayan Swiftlet

Aerodramus brevirostris

French: Salangane de l'Himalaya

German: Himalayasalangane

Spanish: Salangana del Himalaya

Other common names: (Indian) Edible-nest Swiftlet(!), Himalayan Swift; Chinese Swiftlet (*innominatus*); Indochinese Swiftlet (*rogersi*); Volcano Swiftlet (*vulcanorum*)

Taxonomy. *Hirundo brevirostris* Horsfield, 1840, Assam.

Genus often merged into *Collocalia*. Races *vulcanorum* and *rogersi* may represent distinct species, particularly the former; *rogersi* may be closely related to *A. unicolor*, but intergrades between *rogersi* and other races of present species may occur; *vulcanorum* has alternatively been considered a race of *A. maximus*. Formerly linked with *A. whiteheadi*, but differs in nest type and rump pattern. Proposed races *inopinus* and *capnitis*, both from Hubei (EC China), are synonyms of *innominatus*; rump colour varies within populations of *innominatus*, dark-rumped individuals having been described as race *pellios*. Four subspecies currently recognized.

Subspecies and Distribution.

A. b. brevirostris (Horsfield, 1840) - Himalayas and mountains of NE India, SC China (W Yunnan), Myanmar and Thailand; winters to SW Thailand and Malay Peninsula and possibly Sumatra.

A. b. innominatus (Hume, 1873) - EC & SC China (Hubei, S Sichuan, N Guizhou, Yunnan) and N Vietnam (NW Tonkin); winters to SW Thailand and Malay Peninsula, occasionally to Andaman Is and possibly Sumatra.

A. b. rogersi (Deignan, 1955) - E Myanmar, W Thailand and N Laos; winters as far S as Surat Thani (S Thailand).

A. b. vulcanorum (Stresemann, 1926) - mountains in W Java.

Descriptive notes. 13-14 cm. Large swiftlet with obviously forked tail; grey rump band clearly paler than dark brown upperparts; underparts very uniform pale grey; lightly feathered tarsi and white rami. Race *innominatus* has darker rump than nominate; *rogersi* smallest race, similar to nominate but lacking white rami and tarsus feathering; *vulcanorum* has darker underparts and obvious pale rump, male with bare tarsi. Capable of echolocation.

Habitat. Primarily in highlands, particularly over wooded river valleys, though not uncommon over wide range of habitats, including cultivated areas. Recorded to 4575 m in Nepal and between 1500-2800 m in C Bhutan. Race *vulcanorum* not recorded away from highland habitats, notably rims of volcanic craters.

Food and Feeding. Diptera and Hymenoptera recorded. Gregarious, typically up to 50; larger flocks, e.g. 300, not uncommon. Associates with other swifts and hirundines. Often descends from hills in evenings or during poor weather to forage over cultivated land, particularly paddies, where areas of standing water especially favoured.

Breeding. Season Apr-Jun, India; eggs collected late Apr, Shan States, Myanmar. Colonial. Nests on vertical rock-faces, inside caves or similar structures; self-supporting bracket-shaped nest of vegetable materials agglutinated with sparse, but firm, saliva. Copulation noted at nest and in air; 2 eggs.

Movements. Partial migrant, with apparently only relatively small proportions of populations moving S for winter. Recorded Nov-Mar in Malay Peninsula. Nocturnal migrants recorded in Nov at Fraser's Hill, W Malaysia, were nominate race or *innominatus*. In Strait of Malacca, 4 on passage through Riau Archipelago

in mid-Sept to early Oct, and 3 of indeterminate race collected in Nov from lighthouse; believed to be common passage migrant on Karimun Besar. Status in Sumatra uncertain, where in past reported to be a breeding resident, but may be merely winter visitor or straggler; large southward movement of c. 2860 swiftlets over S Serkap in early Oct probably refers to this species. Nominate race is altitudinal migrant in parts of Himalayas, wintering at 900-2750 m in Nepal; a few records from NE Bangladesh, where species may be only irregular winter visitor. Type specimen of race *innominatus* from S Andamans, where species is probably only rare straggler in winter. Race *vulcanorum* strictly resident. Race *rogersi* not known with certainty S of Surat Thani; has been recorded in SW Yunnan (SC China).

Status and Conservation. Not globally threatened. Common throughout most of breeding range, though is an uncommon wintering species in Malay Peninsula; rather rare in China; recorded as a rare winter visitor in New Forest, Dehra Dun, N India; in suitable habitat, for instance in N Thailand, species can be abundant, and is especially obvious around dusk; first records for W Myanmar as recently as 1994. Race *vulcanorum* sometimes considered full species and classified as Vulnerable; also as restricted-range species, present in Java and Bali Forests EBA; all recent records from 1 site, Gunung Gede, where species is not always seen by visiting ornithologists; it has been suggested that active volcanoes around which it occurs occasionally cause localized extinction; this threat, together with scarcity of suitable breeding habitat, suggests that this form has always been rare and would present considerable problems for conservation management.

Bibliography. Ali & Ripley (1983), Ali *et al.* (1996), Bangs & Van Tyne (1931), Cheng Tsohsin (1983), Clayton *et al.* (1996), Collar *et al.* (1994), David-Beaulieu (1994), Deignan (1945, 1955b), Étchécopar & Hue (1978), Fan Zhiyong & He Feng (1997), Glennie (1944), Grimmett *et al.* (1998), Hale & Kennerley (1994), Holmes (1996), Inskipp *et al.* (1996), Lee *et al.* (1996), Lekagul & Round (1991), Li Dewu *et al.* (1981), MacKinnon & Phillips (1993), van Marle & Voous (1988), Medway (1966), Medway & Pye (1977), Medway & Wells (1976), Mohan (1997), Ollington & Loh (1996), Pratt (1986), Riley (1938), Ripley (1982), Robson (1995a, 1997a), Robson *et al.* (1998), Salomonsen (1983), Smythies (1986), Somadikarta (1967), Stattersfield *et al.* (1998), Stresemann (1931a), Tymstra *et al.* (1997), Wells (1999), Xiong Tieyi (1988), Zhao Zhengjie (1995).

27. Whitehead's Swiftlet

Aerodramus whiteheadi

French: Salangane de Whitehead

Spanish: Salangana de Whitehead

German: Philippinensalangane

Other common names: Whitehead's Mountain Swiftlet

Taxonomy. *Collocalia whiteheadi* Ogilvie-Grant, 1895, Mount Data, Luzon. Genus often merged into *Collocalia*. In past considered conspecific with *A. orientalis*, but apparently not closely related. Formerly linked with *A. brevirostris*, but differs in nest type and rump pattern. Has also been considered conspecific with *A. papuensis*, but does not lack fourth toe. Two forms previously listed as races of present species have now been synonymized with other congeneric taxa: *tsubame* with *A. vanikorensis palawanensis*; and *apoensis* with *A. mearnsi*. Many old records attributed to this species actually refer to *A. vanikorensis amelis*. Two subspecies recognized.

Subspecies and Distribution.

A. w. whiteheadi (Ogilvie-Grant, 1895) - Mt Data on Luzon (N Philippines).

A. w. originis (Oberholser, 1906) - Mt Apo on Mindanao (S Philippines).

Descriptive notes. 14 cm. Large swiftlet with massive head and deep tail-fork; black-brown upperparts with some white rami but lacking paler rump; extensive pale fringing to lores and over eye; paler brown underparts; naked tarsi. Race *originis* darker above and below. No information available as to whether or not species is capable of echolocation.

Habitat. Recorded only from naturally forested, montane sites.

Food and Feeding. Not known.

Breeding. Nestling and nests collected from Mt Apo early Jul, where 4 rounded nests found in hollow tree, consisting of green bryophytes

with fibrous vegetable matter but apparently lacking saliva nest-cement, are considered by some to have been made by *originis*.

Movements. Presumed resident.

Status and Conservation. VULNERABLE. Restricted-range species: present in Luzon EBA and Mindanao and the Eastern Visayas EBA. Clearly in need of further study. Recent specimens collected from S Cotabato, Mindanao, may or may not relate to records from Mt Matutum in Nov 1993. May be at risk from habitat loss.

Bibliography. Anon. (1997b), Clayton *et al.* (1996), Collar *et al.* (1994), Delacour & Mayr (1946), Dickinson (1989a), Dickinson *et al.* (1991), Inskipp *et al.* (1996), McGregor (1904), Medway (1966), Oberholser (1906), Ogilvie-Grant (1895), Poulsen (1995), Pratt (1986), Salomonsen (1983), Somadikarta (1967), Stattersfield *et al.* (1998), Stresemann (1914a, 1914b, 1926).

28. Bare-legged Swiftlet

Aerodramus nudatarsus

French: Salangane de Salomonsen

Spanish: Salangana Tarsidesnuda

German: Nacktfußsalangane

Other common names: Schrader Mountain/New Guinea/Naked-legged Swiftlet

Taxonomy. *Collocalia nudatarsus* Salomonsen, 1963, Baroka, Bioto Creek, New Guinea. Genus often merged into *Collocalia*. Sometimes treated as forming a superspecies with *A. orientalis*, and thence also linked with *A. whiteheadi*. Monotypic.

Distribution. S & SE New Guinea. May breed N of central watershed in Schrader Range.

Descriptive notes. 14 cm. Large swiftlet with shallow tail-fork; dark brown above, rump uniform, with extensive pale fringes on lores and over eye; uniformly sooty-grey underparts; apparently some variation in rami colouring. Bare tarsi, glossless upperparts and presence of 4 toes distinguish present species from *A. papuensis*. No information available as to whether or not species is capable of echolocation.

Habitat. Collected mainly in highlands, though also as low as 30 m above sea-level.

Food and Feeding. Not known.

Breeding. No information available.

Movements. Resident.

Status and Conservation. Not globally threatened. Restricted-range species: present in Central Papuan Mountains EBA. Believed to be uncommon, and certainly species is relatively uncommon in museum collections. Biology and ecology almost totally unknown; extensive research required.

Bibliography. Beehler *et al.* (1986), Coates (1985), Diamond (1972), Pratt (1986), Rand & Gilliard (1967), Salomonsen (1962, 1983), Somadikarta (1967), Stattersfield *et al.* (1998).

29. Mayr's Swiftlet

Aerodramus orientalis

French: Salangane de Mayr

German: Salomonensalangane

Spanish: Salangana de Guadalcanal

Other common names: Guadalcanal Swiftlet

Taxonomy. *Collocalia lowi orientalis* Mayr, 1935, Guadalcanal, Solomon Islands.

Genus often merged into *Collocalia*. Sometimes treated as forming a superspecies with *A. nudatarsus*. Formerly considered conspecific with *A. whiteheadi*. A specimen from Bougainville

I was intermediate in size between nominate and race *leletensis*; although some plumage details were rather different, it was provisionally thought to belong within this species. Two subspecies currently recognized.

Subspecies and Distribution.

A. o. leletensis Salomonsen, 1963 - C New Ireland.

A. o. orientalis Mayr, 1935 - Guadalcanal (Solomon Is.).

Also known from Bougainville I, though taxonomic assignment of the only specimen requires further investigation.

Descriptive notes. 13-14 cm. Large swiftlet with proportionally short tail and shallow tail-fork; black upperparts with broad, pale grey rump, pale fringes to lores and over eye; uniformly sooty-brown underparts; thinly feathered tarsi. Race *leletensis* has glossy blue-black upperparts, slightly darker and narrower rump-band and naked tarsi. No information available as to whether or not species is capable of echolocation.

Habitat. Not well known, but assumed to be a highland species.

Food and Feeding. Not known.

Breeding. No information.

Movements. Apparently resident, though very little known.

Status and Conservation. Not globally threatened. Restricted-range species: present in New Britain and New Ireland EBA and Solomon Group EBA. Data-deficient. Known with certainty only from 2 specimens, collected in 1935 on Guadalcanal and in 1962 on New Ireland. Sightings of unidentified large swiftlets on New Georgia in Jul 1987 and on Manus in May 1989, coupled with Bougainville specimen of Jun 1979, suggest that this species may prove to have a more extensive range than currently thought; survey work required, as is research into basic biology of species.

Bibliography. Blaber (1990), Coates (1985), Collar *et al.* (1994), Hicks (1992a), Pratt (1986), Ripley (1983), Salomonsen (1962, 1983), Somadikarta (1967), Stattersfield *et al.* (1998).

30. Mossy-nest Swiftlet

Aerodramus salangana

French: Salangane de la Sonde

German: Moosnestsalangane

Spanish: Salangana de la Sonda

Other common names: Mossy/Sunda Swiftlet

Taxonomy. *Hemiprocne salangana* Streubel, 1848, Java.

Genus often merged into *Collocalia*. Forms superspecies with *A. vanikorensis*, *A. pelewensis*, *A. bartschi* and *A. inquietus*; all were formerly considered conspecific. Race *aerophilus* of doubtful validity; often placed in *A. fuciphagus*. Races *A. vanikorensis aenigma* and *A. v. heinrichi* sometimes considered to belong to present species. Four subspecies recognized.

Subspecies and Distribution.

A. s. natunae (Stresemann, 1930) - N Borneo, and probably Sumatra and Natuna Is.

A. s. maratua (Riley, 1927) - Maratua Archipelago (off NE Borneo).

A. s. aerophilus (Oberholser, 1912) - islands off W Sumatra, including Nias.

A. s. salangana (Streubel, 1848) - Java.

Descriptive notes. 12 cm; 23 g. Medium-sized swiftlet with shallow tail-fork; uniform black-brown upperparts; uniform pale brown underparts. Race *natunae* averages longer-winged and has feathered tarsi; *maratua* and *aerophilus* smaller than other 2 races, *maratua* averaging paler than *aerophilus* which has deepest tail-fork (11-13%) and naked tarsi. From sympatrics only safely distinguishable in hand or on nest; tarsal feathering variable, very light or lacking in nominate; light shaft streaking on underparts, lacking in some; grey-brown rami to back feathers. Nominat and race *natunae* both capable of echolocation.

Habitat. Feeds over variety of habitats adjacent to breeding caves. Apparently feeds at lower levels and closer to nest than sympatric *A. maximus* and for shorter periods, though both feed together at swarms. Particularly favours caves in primary forest.

Food and Feeding. At Niah, Sarawak, 22 families and subfamilies of insects taken, certain beetles and swarming ants and termites predominating. Highly gregarious, associating with congeners and most active during crepuscular period. Feeds both amidst forest canopy and at lower elevations.

Breeding. Certain active colony studied Mar. Padang Highlands, Sumatra, and further probable record of active colony in limestone cave with *A. maximus* in Apr in same highlands; at Niah, breeds over 8 months from Sept to Apr. Colonial cave nester. Nest of vegetable matter agglutinated with sparse transparent saliva which remains soft and moist; requires support by ledge or similar irregularity. Two eggs, though 1 recorded; interval 2 days; both sexes brood but replacement of brooding bird does not occur during day; replacement and second clutches recorded; incubation period 19-27 days, mean 23. Fledging period where both young survived, 41-56 days, mean 48-5, compared with 41-55, mean 48, where only 1 survived after 2 hatched; young fed several times daily. Average breeding success 38% with 0.8 young fledged per breeding effort.

Movements. Presumed resident. Single record from Philippines (Basilan) suggests some degree of dispersal.

Status and Conservation. Not globally threatened. Believed to be uncommon on Java, though identification problems may disguise true status; otherwise locally abundant. Occurs in Gunung Mulu National Park, Sarawak; range might extend to S half of Borneo.

Bibliography. Chapman (1985), Clayton *et al.* (1996), Cranbrook (1984), Dickinson (1989a), Dickinson *et al.* (1991), Harrison (1974), Hellebrekers & Hoogerwerf (1967), Inskipp *et al.* (1996), Lee *et al.* (1996), MacKinnon (1988), MacKinnon & Phillips (1993), van Marle & Vovus (1988), Medway (1961, 1962a, 1962b, 1966), Oberholser

(1932), Pratt (1986), Riley (1927), Robinson & Kloss (1924), Salomonsen (1983), Seitre, J. & Seitre (1991), Seitre, R. & Seitre (1992), Smythies (1981), Wells (1975).

31. Uniform Swiftlet

Aerodramus vanikorensis

French: Salangane de Vanikoro **German:** Einfarbsalangane **Spanish:** Salangana de Vanikoro
Other common names: Island/Lowland/Vanikoro Swiftlet; Grey/Philippine Swiftlet(!) (*amelis*); Palawan Swiftlet (*palawanensis*)

Taxonomy. *Hirundo vanikorensis* Quoy and Gaimard, 1830, Island of Vanikoro. Genus often merged into *Collocalia*. Forms superspecies with *A. salangana*, *A. pelewensis*, *A. bartschi* and *A. inquietus*; all were formerly considered conspecific; *A. mearnsi* was previously included in this superspecies too. Both *A. infuscatus* and *A. hirundinaceus* have been treated as races of present species. Races *palawanensis* and *amelis* sometimes considered two (or one) distinct species; former has been treated as conspecific with *A. maximus* or *A. whiteheadi*, and latter with *A. fuciphagus*. Races *aenigma* and *heinrichi* sometimes considered to belong to *A. salangana*. Population on Yamdena in Tanimbar Is not yet subspecifically assigned and may belong to an undescribed race. Australian birds formerly treated alone as race *yorki*, with name *granti* applied to New Guinea birds; however, the only two Australian records refer to vagrants identical to the New Guinea form, and it is clear that only a single race is involved; this race often listed as *granti*, but name *yorki* has priority by 21 years. Proposed race *isubame* of *A. whiteheadi* now considered a synonym of race *palawanensis*. Fourteen subspecies currently recognized.

Subspecies and Distribution.

A. v. amelis (Oberholser, 1906) - Luzon, Mindoro, Cebu, Bohol and Mindanao (E Philippines).
A. v. palawanensis (Stresemann, 1914) - Palawan (SW Philippines).
A. v. aenigma (Riley, 1918) - C Sulawesi.
A. v. heinrichi (Stresemann, 1932) - Sulawesi.
A. v. moluccarum (Stresemann, 1914) - Seram, Ambon, Banda, Gorong, Tayandu and Kai Is (S Moluccas).
A. v. waigeuensis (Stresemann & Paludan, 1932) - N Moluccas (Morotai, Halmahera) and W Papuan Is (Misool, Batanta, Waigeo and probably Salawati).
A. v. steini (Stresemann & Paludan, 1932) - Biak and Numfor (in Geelvink Bay, NW New Guinea).
A. v. yorki (Mathews, 1916) - Aru Is, New Guinea and D'Entrecasteaux Is.
A. v. tagulae (Mayr, 1937) - Louisiade Archipelago, Trobriand Is and Woodlark I.
A. v. coultasi (Mayr, 1937) - Admiralty Is (Manus, Rambutuy, Los Negros) and St Matthias group.
A. v. pallens (Salomonsen, 1983) - New Hanover, New Ireland and nearby Djaul I, and New Britain.
A. v. lihiensis (Mayr, 1937) - Nuguria and Hibernian Is, Tabar Is, Lihir group and Feni Is (E of New Ireland).
A. v. lugubris (Salomonsen, 1983) - Solomon Is.
A. v. vanikorensis (Quoy & Gaimard, 1830) - Santa Cruz Is (including Duff Is and Swallow Is) and Vanuatu.
Also (subspecies unknown) Yamdena in Tanimbar Is.

Descriptive notes. 13 cm. Medium-sized swiftlet with moderately forked tail; grey-brown above; slightly darker undertail-coverts on otherwise pale grey-brown underparts; limited darker shaft-streaking. Highly variable, with rump uniform with upperparts in all races except *pallens* which has at best an indistinctly paler rump. Philippine races separable from each other on wing length, *amelis* shorter than *palawanensis*; *aenigma* dark, blackish above with blue-green gloss and dark grey-brown below, with extensive white rami to rump area; *heinrichi* paler below and green-glossed above; *moluccarum* as *aenigma* with larger eye-patch

and greater fringing on undertail-coverts; small *waigeuensis* darker than *aenigma* but with paler throat and upper breast, lacking dark shaft streaks; *steini* larger and darker than *waigeuensis*; *granti* blacker above with paler throat and relatively short tail; *tagulae* with paler underparts and darker throat than nominate; *pallens* darker above than *tagulae* with extensive white rami and hence pale rump and whitish throat; *coultsi* paler above than *pallens*; *lugubris* uniformly blackish above with white rami absent or much reduced and underparts dark grey; *lihiensis* intermediate between latter 2 forms. Capable of echolocation.

Habitat. Occurs over variety of habitats, mainly forest, including coasts and islands, from lowlands to over 500 m on Sulawesi and 700 m on Seram. Found from lowlands to highlands, New Guinea to 1400 m and Goodenough I to 1600 m. On Santa Isabel mainly in lowlands, to 900 m over gardens and second-growth. In lowland rainforest zone of Papua New Guinea recorded over forest, forest edge and non-forest.

Food and Feeding. Highly gregarious, associating with congeners. Highly transient when foraging. Feeds at lowest elevations when over open country; feeds throughout day but still active at dusk. Insect prey size 1-6 mm recorded in Bismarck Archipelago.

Breeding. Season Aug-Dec, sometimes to Feb. Vanuatu; breeding New Guinea at Musgrave R and Mafulu, both Central Province, in Aug and Oct respectively, and on Goodenough I in Oct; breeds in Jun on Luzon, Philippines. Colonial. Typically nests in total darkness in cave or similar structure; 1 nest noted under overhanging bank of earth on side of stream. Described nests tend to be rounded, though bracket-like, composed of strands of vegetable matter and agglutinated with moderate to sparse amount of saliva; some have at least partial support. Clutch 1-2.

Movements. Resident, but with some evidence of local movements. Numbers known to fluctuate in some places, e.g. at Waigani Bay (SE New Guinea) with increase Nov-Dec but decrease in Feb. Vagrant to Queensland (NE Australia), with two confirmed records (one producing type specimen of race *yorki*) and several more reports of possible sightings. Often moves along fronts of storms.

Status and Conservation. Not globally threatened. Common to abundant throughout range. Reported as common in C Sulawesi in early 1980's. Occurs in several protected areas throughout range, e.g. in Philippines: *palawanensis* in Saint Paul Subterranean National Park, Palawan; and *amelis* in Rajah Sikatuna National Park, Bohol. Race *palawanensis* sometimes considered full species and classified as restricted-range species; present in Palawan EBA.

Bibliography. Bechler, Pratt & Zimmerman (1986), Bechler, Sengo *et al.* (1995), Blaber (1990), Bravery (1971, 1973), Bregulla (1992), Brooks *et al.* (1996), Browning (1993), Cain & Galbraith (1956), Clayton *et al.* (1996),

32. Palau Swiftlet

Aerodramus pelewensis

French: Salangane des Palau **German:** Palausalangane **Spanish:** Salangana de las Palau

Taxonomy. *Collocalia pelewensis* Mayr, 1935, Palau Islands.

Genus often merged into *Collocalia*. Forms superspecies with *A. salangana*, *A. vanikorensis*, *A. bartschi* and *A. inquietus*; all were formerly considered conspecific. Previously placed in *A. bartschi*, and sometimes also associated with *A. fuciphagus germani* and *A. f. inexpectatus*. Monotypic.

Distribution. Palau Is.

Descriptive notes. 11 cm. Small swiftlet with relatively short, moderately forked tail; black-brown upperparts with grey-brown rump; underparts palest on throat, darkest on undertail-coverts, rest dull grey; shaft streaks most distinct on undertail-coverts; lacks supraloral spot and tarsal feathering. From other Micronesian swiftlets by pale rump, and from *A. bartschi* by more glossy black plumage, greyer ventrally on underparts, and longer wings; both *A. bartschi* and *A. inquietus* have a shallower tail-fork. Available information suggests species probably capable of echolocation.

Habitat. Occurs on larger islands of group. Most numerous flocks typically over highland ridges and gorges, shying from deep forest.

Food and Feeding. Most active at dusk when forms largest flocks. Small flocks forage in a restricted area for long periods during day.

Breeding. Active colony on Malakal I in mid-Oct. Colonial, nesting in caves. Very flat nests attached to cave roof are lined with moss and fine grass; 95 mm wide x 35 mm deep, cup diameter 50 mm. 1 egg.

Movements. Resident.

Status and Conservation. Not globally threatened. Restricted-range species; present in Palau EBA. Common to abundant within small range, with no large population change noted between 1949 and 1988.

Bibliography. Baker (1951), Brandt (1966), Browning (1993), Engbring (1988), Marshall (1949), Mayr (1935, 1937a, 1945), Medway (1966, 1975b), Pratt (1986), Pratt, Bruner & Berrett (1987), Pratt, Engbring *et al.* (1980), Salomonsen (1983), Stattersfield *et al.* (1998).

33. Guam Swiftlet

Aerodramus bartschi

French: Salangane de Guam **German:** Marianensalangane **Spanish:** Salangana de Guam
Other common names: Micronesian(!)/Guam Cave/Mariana Swiftlet

Taxonomy. *Collocalia bartschi* Mearns, 1909, Guam.

Genus often merged into *Collocalia*. Forms superspecies with *A. salangana*, *A. vanikorensis*, *A. pelewensis* and *A. inquietus*; all were formerly considered conspecific. Previously lumped with *A. pelewensis*, and sometimes also associated with *A. fuciphagus germani* and *A. f. inexpectatus*. Considered a race of *A. inquietus* by some authors. Monotypic.

Distribution. Saipan, Tinian and Guam in S Mariana Is. Introduced to Oahu, Hawaii.

Descriptive notes. 11 cm. A small swiftlet with a moderately forked tail; warm brown upperparts lacking sheen and with uniform rump; underparts darker grey beneath silver-grey throat; tarsi bare or lightly feathered; supraloral patch missing or much reduced; underparts lack shaft streaks. Notably paler than *A. inquietus*. Available information suggests the species is probably capable of echolocation.

Habitat. Occurs over a wide range of cleared and forested habitats in interior and on coast, including mangroves.

Food and Feeding. Tends to be most noticeable

gregarious in evenings when large groups feed very low, not moving up and away until nightfall. Feeding times and habits similar to those of sympatrically occurring sheath-tailed bats (*Emballonura*).

Breeding. Active colonies Mar-May. Colonial, up to 250 nests with clusters of 25-50. Nest cylindrical, birds adding to it each season, supported by niche in cave wall; composed of moss agglutinated by large amounts of hardened saliva.

Movements. Nomadic movements account for occasional temporary gatherings at dusk or for longer periods, and absence from certain islands.

Status and Conservation. Not globally threatened. Restricted-range species; present in Mariana Islands EBA. Marked decline seems apparent since species was recorded as abundant on both Guam and Saipan in 1949. By 1987, it had become extinct on Rota, was approaching extinction on Guam and was uncommon on Saipan, Tinian and Agiguan; conservation status probably requires reassessment; surveys needed. Introduced to Oahu, Hawaii, in 1962, and now breeds in Halawa and Moanalua Valleys, although population appears to be very small; 12 pairs found breeding in 1989.

Bibliography. Anon. (1991, 1998a), Baker (1951), Brandt (1966), Browning (1993), Jenkins (1979, 1983), Lee *et al.* (1996), Marshall (1949), Mayr (1937a, 1945), Mearns (1909b), Medway (1966), Pratt (1986), Pratt *et al.* (1979, 1987), Stophlet (1946), White, T. (1996).

34. Caroline Swiftlet

Aerodramus inquietus

French: Salangane des Carolines **German:** Karolinsensalangane **Spanish:** Salangana de las Carolinas
Other common names: Micronesian Swiftlet(!)

Taxonomy. *Cypselus inquietus* Kittlitz, 1858, Kosrae, Caroline Islands. Genus often merged into *Collocalia*. Forms superspecies with *A. salangana*, *A. vanikorensis*, *A. pelewenis* and *A. bartschi*; all were formerly considered conspecific. Considered conspecific with *A. bartschi* by some authors. Three subspecies recognized.

Subspecies and Distribution.

A. i. rukensis (Kuroda, 1915) - Chuuk (C Caroline Is).
A. i. ponapensis (Mayr, 1935) - Pohnpei (E Caroline Is).
A. i. inquietus (Kittlitz, 1858) - Kosrae (E Caroline Is).

Descriptive notes. 11 cm. Small swiftlet with moderately forked tail, shallower than in *A. pelewenis*; underparts uniformly dark grey-brown. Race *ponapensis* has black-brown upperparts with faint green gloss and can show slightly paler rump; *rukensis* has slightly shorter wing. Uncertain whether or not species is capable of echolocation.

Habitat. Occurs over both open and forested habitats.

Food and Feeding. Virtually nothing known; assumed to be similar to congeners.

Breeding. Active colony with eggs in various stages of incubation Kosrae, mid-May;

eggs collected Jokaz, Apr. May and Aug. during 1958 and 1959; eggs recorded Chuuk, Apr. May, Jul, Sept, Nov and Dec. Colonial. Race *rukensis* nests in total darkness, nominate race and *ponapensis* in less dark situations. Nest of *rukensis* deeply cupped, firmly attached to cave wall, of vegetable matter and some feathers agglutinated with large amounts of saliva; *ponapensis* typically nests in clusters, making distinctly rounded, bracket-type nest of moss and soft vegetable matter with saliva used only at point of attachment to cave wall. Race *rukensis* lays 2 eggs, nominate race and *ponapensis* only 1.

Movements. Resident.

Status and Conservation. Not globally threatened. Restricted-range species: present in East Caroline Islands EBA. Common to abundant. Population estimates of 27,900 birds on Kosrae, 29,800 on Pohnpei and 25,800 on Chuuk, published 1993. Status on Yap I uncertain, whence there is a 19th-century sighting of a swiftlet species.

Bibliography. Baker (1951), Brandt (1962, 1966), Browning (1993), Mayr (1935, 1945), Medway (1966), Pratt (1986), Pyle & Engbring (1985), Ralph & Sakai (1979), Stattersfield *et al.* (1998).

35. Atiu Swiftlet

Aerodramus sawtelli

French: Salangane de Cook **German:** Atiusalangane **Spanish:** Salangana de las Cook
Other common names: Cook (Islands)/Sawtelli's Swiftlet

Taxonomy. *Aerodramus sawtelli* Holyoak, 1974, Atiu Island.

Genus often merged into *Collocalia*. Has been considered to form a superspecies with *A. leucophaeus*, or even to be conspecific, but apparently differs in nest habits. May prove to be merely a race of *A. spodiopygius*, which is very similar in size and plumage and which occurs not far from Cook Is. Monotypic.

Distribution. Atiu I (S Cook Is).

Descriptive notes. 10 cm. Small to medium-sized swiftlet with relatively long, forked tail; black-brown upperparts with contrastingly pale grey rump; pale grey-brown underparts appearing darkest on undertail-coverts; pale supraloral patch reduced or missing. Separable from *A. leucophaeus leucophaeus* by smaller size, shorter tail, paler bases to uppertail-coverts, paler underparts and different bill structure; *A. l. ocistus* somewhat intermediate. Capable of echolocation.

Habitat. Occurs over both open and forested habitats.

Food and Feeding. Little known. Forages

slowly amidst forest canopy and along forest margins.

Breeding. Most nests built Sept with last chicks fledged Apr. Colonial cave breeder. Nest typically bracket-and-cup-shaped and self-supporting using a small quantity of saliva, though those on ledges had cups supported upon a base. Nest composed primarily of plant material, mostly coconut crown fibre and lichens with lesser quantities of *Casuarina* needles, grass, angiosperm leaves and passion-fruit (*Passiflora*) tendrils; other components include feathers from this species and less commonly its own eggshells and flowers of *Ocimum gratissimum*. Two eggs, both sexes incubating; sometimes 2 broods. Average weight of young 1.1 g at hatching and 9.5 g when they fledge; fledging period averages 53 days.

Movements. Resident.

Status and Conservation. VULNERABLE. Restricted-range species: present in Southern Cook Islands EBA. No decline apparent to date. There were thought to be only 60 nests when species was first discovered in 1973. Census in 1987-1988 recorded 190 active nests in two caves; in addition, other smaller colonies are believed to exist. Recent studies show density of 1 breeding bird per 7 ha, equivalent to total of 380 breeding birds on the island. Crab predation and starvation after falling from nest are main causes of fledgling mortality. Tourist disturbance may pose future problem.

Bibliography. 36. Polynesian Swiftlet

Aerodramus leucophaeus

French: Salangane de la Société **German:** Polynesiensalangane **Spanish:** Salangana Polinesia
Other common names: South Pacific Swiftlet; Tahiti/Tahitian Swiftlet (*leucophaeus*); Marquesas/Marquesan Swiftlet (*ocistus*)

Taxonomy. *Macropteryx leucophaeus* Peale, 1848, Tahiti.

Genus often merged into *Collocalia*. Has been considered to form a superspecies with *A. sawtelli*, or even to be conspecific, but apparently differs in nest habits. Race *ocistus* (with *gilliardi*) sometimes considered a distinct species, being intermediate in some features between nominate race and *A. sawtelli*. Variation in relative pallor of rump within birds of Tahitian population led to past recognition of pale-rumped race "thespesius", but this is now considered to fall within normal variation of nominate race. Three subspecies currently recognized.

Subspecies and Distribution.

A. l. leucophaeus (Peale, 1848) - Moorea and Tahiti (E Society Is).
A. l. ocistus (Oberholser, 1906) - Eiao, Nuku Hiva and Ua Huka (N Marquesas).
A. l. gilliardi (Somadikarta, 1994) - Ua Pu, Hiva Oa and Tahuata (S Marquesas).

Descriptive notes. 11 cm. Medium-sized swiftlet with proportionally long, forked tail; plumage appears rather uniform: dark-brown upperparts with grey rump, which may be paler ("thespesius") or darker; grey-brown underparts. Less contrast between upperparts and underparts than in *A. sawtelli*, which has paler underparts. Races *ocistus* and *gilliardi* somewhat intermediate between nominate race and *A. sawtelli* and differ further from both in proportionally longer tail; race *gilliardi* differs from *ocistus* in having naked tarsi, slightly longer wings and tail, and slightly deeper tail-fork. Race *ocistus* (and presumably *gilliardi*)

capable of echolocation; nominate unknown.

Habitat. Occurs over riverine habitats, rocky valleys and humid forests.

Food and Feeding. Race *ocistus* apparently more gregarious than nominate race, perhaps due to larger size of population. Nominat feeds at high elevations over range of habitats recorded for species, while *ocistus* apparently forages slowly amidst forest canopies and margins.

Breeding. Nests collected Marquesas in Oct. Colonial, up to 300 birds reported. Wide variety of nest-sites: caves, deep or shallow, depressions under rocks or coastal cliffs. Self-supported or externally supported nest of vegetable matter agglutinated with sparse, sticky saliva. 2 eggs.

Movements. Resident, but may be only vagrant to Moorea, suggesting that some dispersal might occur.

Status and Conservation. Not globally threatened. When treated as two distinct species both forms are restricted-range species: *leucophaeus* present in Society Islands EBA; *ocistus* present in Marquesas Islands EBA. Nominat *leucophaeus* classed as Vulnerable; has declined in 20th century possibly as a result of predation on chicks and eggs by introduced Common Mynas (*Acridotheres tristis*); found in only 6 of 39 Tahitian valleys during surveys of 1986-1991; total population estimate of 200-500 birds in 1984; extinct on Huahine, easternmost of W Society Is. Other races common on most islands in Marquesas, but not on Hiva Oa, where may also suffer from presence of introduced Common Myna.

Bibliography. Berlioz (1929b), Clayton *et al.* (1996), Collar & Andrew (1988), Collar *et al.* (1994), Fisher & Wetmore (1931), Holyoak (1974b, 1975), Holyoak & Thibault (1978, 1984), Medway (1966), Medway & Pye (1977), Monnet *et al.* (1993), Oberholser (1906), Pratt (1986), Pratt *et al.* (1987), Salomonsen (1983), Somadikarta (1994), Stattersfield *et al.* (1998), Thibault (1988), Thibault & Rives (1988).

37. Black-nest Swiftlet

Aerodramus maximus

French: Salangane à nid noir **German:** Schwarzneestsalangane **Spanish:** Salangana Nidonegro
Other common names: Indo-Malayan Swiftlet; Robinson's Swiftlet (*maximus*); Lowe's Swiftlet (*lowi*)

Taxonomy. *Collocalia maxima* Hume, 1878, Tenasserim.

Genus often merged into *Collocalia*. Much confusion over nomenclature: species originally named *maxima* in 1876, but incorrectly: validated by same author in 1878; however, this emendation was long overlooked, in part due to lumping of these names within *A. brevirostris innotatus*, an older name; during this period name used for present species was *lowi*, while northern race was listed as *robinsoni*, as next available name. Despite the unlikely distribution pattern resulting, nominate race and *lowi* apparently co-occur and intergrade in W Java. Both *A. brevirostris vulcanorum* and *A. vanikorensis palawanensis* have been placed in present species. Three subspecies recognized.

Subspecies and Distribution.

A. m. maximus (Hume, 1878) - S Myanmar to S Malay Peninsula, SE Vietnam and W Java.
A. m. lowi (Sharpe, 1879) - Sumatra and islands off W coast, N, W & S Borneo, Labuan I and W Java.
A. m. tichelmani (Stresemann, 1926) - SE Borneo.

Descriptive notes. 12-14 cm; 28 g. Medium-sized to large swiftlet with comparatively shallow tail-fork; glossy black-brown upperparts with typically uniform rump, though some have greyish rump; underparts grey, palest on throat and darker from chest, becoming darkest on belly and undertail-coverts; rami of back dark-tipped with only traces of white. In hand averages longer than *A. salangana* or *A. fuciphagus*. Differs from *A. brevirostris* by heavy tarsal feathering and less deeply forked tail. Race *lowi* has darkest rump; *tichelmani* smallest, with rump similar to nominate. Both nominate and *lowi* capable of echolocation; *tichelmani* unknown.

Habitat. Occurs from lowlands to highlands over range of habitats, including dense forest where adjacent to breeding colonies.

Food and Feeding. At Niah, Sarawak, 14 insect families and subfamilies recorded, with ants, termites and certain beetles predominating. Takes advantage particularly of swarming insects. Apparently feeds at higher levels and farther from nest than sympatric *A. salangana* and for longer periods.

though both feed together at swarms. Highly gregarious, often flocking with congeners, most active in crepuscular period. It has been speculated that it may be able to feed on swarms in the dark, as some termites and ants swarm from sunset into full darkness.

Breeding. Eggs collected on Thai Peninsula, mid-Apr; active colony in Padang Highlands, Sumatra, Apr; builds nests above high-tide mark from Feb, some eggs laid from early Mar, in Mergui Archipelago, Myanmar; at Niah, breeds Sept-Apr in unfarmed sites, though occasionally outside this season. Colonial cave nester, often sharing caves with *A. fuciphagus*, *A.*

salangana and *Collocalia esculenta*. Self-supporting, bracket-shaped nest made of large amounts of firm translucent saliva and feathers from any part of plumage; nest-building takes from 35 to over 127 days. One egg; both sexes brood but changeover does not occur during day; replacement and second clutches recorded; incubation 24-32 days, mean 28. Fledging period 52-65 days, mean 58.5; nestling fed infrequently, in 2 nests just once and twice in 24 hours (chick dying in first case), but feeding always occurs when adults return to roost. Average breeding success 17% with 0.2 young fledged per breeding effort.

Movements. Resident, though vagrancy to Palawan suggests some dispersal.

Status and Conservation. Not globally threatened. Scarcest in Malay Peninsula. Elsewhere abundant, despite alarming decrease at some farmed caves, e.g. 150,000-298,000 birds estimated at Niah caves in early 1990's where over 1,500,000 pairs estimated as recently as 1959. In 1950's it was thought that over 500,000 eggs or nestlings of this species and next were lost in 1 cave alone due to harvesting. Recorded in Vietnam only on islets off coast of Khanh Hoa province since 1981, where there were 65 nests in 1994.

Bibliography. Ali & Ripley (1983), Ali *et al.* (1996), van Balen & Prentice (1997), Basir *et al.* (1996), Brandt (1966), Clayton *et al.* (1996), Cranbrook (1984), Davison (1997a), Deignan (1955a), Dickinson (1989a), Dickinson, Kennedy & Parkes (1991), Dickinson, Kennedy, Read & Rozendaal (1989), Good (1993), Good & Wong (1989), Harrison (1974), Holmes & van Balen (1996), Inskipp *et al.* (1996), Kang & Lee (1991), Kang *et al.* (1991), Kenneth *et al.* (1995), Krueger (1966), Lee, P.G. (1984), Lee, P.G. & Kang (1994), Lee, P.L.M. *et al.* (1996), Lekagul & Round (1991), MacKinnon & Philipps (1993), Mardiatuti (1996), Mardiatuti & Marnata (1996), Mardiatuti & Soehartono (1996), van Marle & Voous (1988), Medway (1961, 1962a, 1962b, 1962c, 1966, 1969), Medway & Pye (1977), Medway & Wells (1976), Nguyễn (1996), Pakpahan & Soehartono (1994), Riley (1938), Robinson & Kloss (1924), Sims (1959, 1961), Smythies (1981, 1986), Stresemann (1931a), Valli & Summers (1990), Wells (1999).

38. Edible-nest Swiftlet

Aerodramus fuciphagus

French: Salangane à nid blanc **German:** Weißnestsalangane **Spanish:** Salangana Nidoblanco
Other common names: Grey-rumped(!)/Hume's/White-nest Swiftlet; Andaman Grey-rumped Swiftlet (*inexpectatus*); German's/Oustalet's Swiftlet (*germani*); Brown-rumped Swiftlet(!) (*vestitus*); Thunberg's Swiftlet (*fuciphagus*)

Taxonomy. *Hirundo Fuciphaga* Thunberg, 1812, Java.

Genus often merged into *Collocalia*. In past, was at various times considered conspecific with many other swiftlet taxa, e.g. *A. francicus* and *A. unicolor*. Race *germani* sometimes considered a distinct species, often including *amechanus*. Races *dammermani* and *micans* often lumped within nominate, and still very poorly known. Proposed race *bartelsi* is synonym of nominate. *A. salangana* *aerophilus* often placed in present species. *A. vanikorensis amelis* has been linked with present species in a superspecies; race *perplexus* has been associated with *amelis*. Eight subspecies currently recognized.

Subspecies and Distribution.

- A. f. inexpectatus* (Hume, 1873) - Andaman and Nicobar Is.
- A. f. amechanus* (Oberholser, 1912) - Anambas Is (off SE Malay Peninsula).
- A. f. germani* (Oustalet, 1878) - coastline from W Hainan to Malay Peninsula, including Mergui Archipelago (off S Myanmar); coastal N Borneo and S Philippines (Palawan to Panay).
- A. f. vestitus* (Lesson, 1843) - Sumatra, Belitung and Borneo.
- A. f. perplexus* (Riley, 1927) - Maratua Archipelago (off E Borneo).
- A. f. fuciphagus* (Thunberg, 1812) - Java, Kangean Is and Bali to W Lesser Sundas and Tanahjampea.
- A. f. dammermani* (Rensch, 1931) - Flores.
- A. f. micans* (Stresemann, 1914) - Sumba, Sawu and Timor.

Descriptive notes. 12 cm; 15-18 g. Medium-sized swiftlet with relatively deeply forked tail; glossy, almost black-brown upperparts with rump typically appearing slightly greyer, though uniform in many; underparts palest and greyest on throat, rest browner grey except blackish undertail-coverts; lightly feathered or naked tarsi; white tips to rami, lacking in some individuals of nominate race and some of *vestitus*. Tail-fork 10-19% of tail length against under 13% in *A. maximus* and *A. salangana*. Race *inexpectatus* similar to nominate but averaging slightly smaller; *dammermani* apparently has slightly paler rump; *micans* paler and greyer with

slightly contrasting rump; *vestitus* has blackest upperparts, typically lacking rump contrast; *perplexus* has rather purple sheen to remiges and rectrices and slightly contrasting rump; *germani* has strikingly pale underparts and broad whitish rump; *amechanus* has greyer rump than *germani*. Nominative and races *amechanus*, *germani*, *vestitus* and *perplexus* all known to be capable of echolocation.

Habitat. Occurs over range of habitats, cleared and forested, coastal and interior, from sea-level to highlands, e.g. to 2800 m on Sumatra. Visits offshore islands and can be seen far out over sea.

Food and Feeding. Analysis of food balls from Penang, Malaysia, revealed following orders account for most prey items: Hymenoptera 41%, Ephemeroptera 26.5%, Homoptera 15.5% and Diptera 7.8%. These were collected during day, however, beetles and night-flying insects were under-represented. Mean foraging height over forested habitat, Malaysia, 57.5 m. Highly gregarious, often in large flocks including congeners, other swifts and hirundines. Most active in crepuscular period.

Breeding. Mainly Mar-Apr on Andaman and Nicobar Is; recorded early Dec, Tanahjampea 1 (N Flores Sea); begins nesting Mar, harvested for second time late Apr and again Jul, non-saliva

content increasing with each collection, peninsular Thailand; breeds Vietnam during first wet season in early Apr, nest-building in dry season Dec-Mar; breeds with *A. maximus*, starting to lay in Apr in Mergui Archipelago, Myanmar; believed to breed Jan-Jun, Palawan. In main study in Penang, breeding may occur year-round but egg-laying concentrated in Sept-Apr, most hatching Nov-Mar in dry season. Colonial, nesting in caves or similar structures, including purpose-built buildings; commonly breeds in urban areas. Nest bracket-shaped and self-supporting, made purely of opaque hardening saliva with extraneous matter rarely incorporated; nest-building takes 39-55 days. 2 eggs; incubation 25.5 days for first egg and 22.5 for second; fledging period 43 days. Hatching success 69%; average breeding success 49% with 0.9 young fledged per breeding effort.

Movements. Resident. Individuals breeding on smaller offshore islands may travel across sea to larger landmasses.

Status and Conservation. Not globally threatened. Abundant in suitable habitat, though declining in many areas as witnessed by reduced nest yields. In 1950's, it was thought that over half a million eggs or nestlings of this and the previous species were lost in 1 cave alone due to harvesting. In Nicobar Is, 1244-1791 pairs breed in 36 caves, and it is estimated that a population decline in excess of 85% has occurred during 1987-1995. Population of Vietnam estimated at c. 200,000 pairs; in decline, due to heavy overexploitation; recent studies, carried out with aim of trying to make harvesting less harmful, suggest limitation to two harvests per year, the first when only c. 10-15% of nests have eggs, and the second when fledglings of a second clutch have left their nests. Locally abundant on Flores and Timor but generally patchily distributed in Wallacea; two possible records from S Sulawesi. Race *germani* historically recorded from Laos, though these records may refer to *A. brevirostris rogersi* and cannot be considered reliable.

Bibliography. Abdulali (1978), Ali & Ripley (1983), Banks (1937), Basir *et al.* (1996), Brandt (1966), Brooks & Dutton (1997), Cheng Tsohsin (1987), Clayton *et al.* (1996), Coates & Bishop (1997), Cranbrook (1984), Delacour (1947), Dickinson (1989a), Dickinson, Kennedy & Parkes (1991), Dickinson, Kennedy, Read & Rozendaal (1989), Good & Wong (1989), Grimmett *et al.* (1998), Hale & Kennerley (1994), Hornslov (1996), Inskipp *et al.* (1996), Jepson (1997), Kang & Lee (1991), Kang *et al.* (1991), Kennerley (1991), Kenneth *et al.* (1995), Langham (1980), Lee, P.G. 39. Papuan Swiftlet

Aerodramus papuensis

French: Salangane papoue **German:** Papuasalangane **Spanish:** Salangana Papú
Other common names: Three-toed Swiftlet, Idenburg (River) Swiftlet

Taxonomy. *Collocalia whiteheadi papuensis* Rand, 1941, Idenburg River, Irian Jaya.

Genus often merged into *Collocalia*. Has been considered conspecific with *A. whiteheadi*, but present species, unique amongst Apodidae, lacks fourth toe. Monotypic.

Distribution. New Guinea: specimens collected from Idenburg R. Snow Mts and Jayapura. Probable sight records from more extensive area of N New Guinea and around Port Moresby in S; first specimen for Papua New Guinea taken from N slopes of Hindenburg Range, Western Province, Apr 1993.

Descriptive notes. 14 cm. Large swiftlet with shallowly forked tail; warm brown, slightly glossy upperparts lacking rump contrast; underparts dark with contrastingly silver-grey throat; densely feathered tarsi; white rami of nape feathers contrast with dark tips. Unique amongst Apodidae in lacking hallux, i.e. has only 3 toes. No information available as to whether or not species is capable of echolocation.

Habitat. Occurs over range of habitats from sea-level to 2400 m. One captured at this upper altitudinal limit was taken at a cave in an area of mossy montane and *Dacrycarpus* forest. May favour gullies in parts of range.

Food and Feeding. Typically feeds at high elevations, though low-level foraging recorded over wetlands. Flocks of 20-30 typical; often with *A. vanikorensis* and *Mearnsia novaeguineae*. In Papua New Guinea one was removed at 06:15 from a net checked at 21:00 previous evening, suggesting crepuscular or even limited nocturnal activity.

Breeding. Not known.

Movements. Resident.

Status and Conservation. Not globally threatened. Thought to be locally common, though lack of definite sightings and scarcity of specimens suggest that this species may actually be rare. Previously considered to be common in Idenburg River area, where flocks of 20-30 individuals were recorded in early 1940's.

Bibliography. Bailey (1992), Beehler *et al.* (1986), Coates (1985), Gregory (1995a, 1995b, 1997), Pratt (1986), Rand (1941), Rand & Gilliard (1967), Rowland, P. (1994), Salomonsen (1962, 1983), Somadikarta (1967, 1975a).

Genus SCHOUTEDENAPUS de Roo, 1968

40. Scarce Swift

Schoutedenapus myoptilus

French: Martinet de Shoa **German:** Maussegler **Spanish:** Vencejo de Shoa
Other common names: Chapin's Swift

Taxonomy. *Cypselus myoptilus* Salvadori, 1888, Let Marefia, Shoa.

Genus previously merged into *Apus*; affinities uncertain. Formerly considered to include *S. schoutedeni* as a race. In past, race *poensis* was considered a race of *Apus unicolor*. Species name sometimes misspelt *myoptilus*. Three subspecies recognized.

Subspecies and Distribution.

S. m. poensis (Alexander, 1903) - Bioko I (Fernando Póo, in Gulf of Guinea).

S. m. chapini (Prigogine, 1957) - E Zaire, Rwanda and SW Uganda.

S. m. myoptilus (Salvadori, 1888) - scattered populations from Ethiopia S to Zimbabwe.

Descriptive notes. 16.5 cm; 22 g. Small swift with long, deeply forked tail appearing needle-thin when closed, bulbous head and thin wings tapering sharply from secondaries; uniform dark grey-brown upperparts with slightly capped appearance; underparts with pale grey throat, mid-brown chest and remainder dark brown, almost chocolate. Race *chapini* has much blacker plumage, while *poensis* is intermediate.

Habitat. Typically in moist highlands, preferably over gorges, waterfalls and evergreen forest. Recorded at 500-2450 m.

Food and Feeding. Flying ants recorded in stomach analysis. Very gregarious; vast single-species flocks, Apr-Aug, in parts of E Zaire. Recorded feeding in large flocks very high over lowland forests, W Kenya, especially in afternoons when poor weather over adjacent highlands may force this lower-altitude feeding. Often forages very low during dry weather, believed to be feeding largely on termites.

Breeding. Egg-laying believed to occur between Sept and Dec in Zimbabwe; analysis of sexual organs suggests breeding occurs in Zaire around Feb and also Sept, while specimens with enlarged gonads were taken in mid-May on Mt Moroto, Uganda, in early Jul at Kapenguria, Kenya, and in early Sept on Mt Mlanje, Malawi; *poensis* may breed in N summer as birds with nearly completed primary moult recorded late Dec to early Jan. Nest not recorded, due to apparent inaccessibility of sites, which are thought to be on cliff-faces or rock clefts, or close to waterfalls on high mountains.

Movements. Typically resident, though regional movements recorded. In E Zaire around Kamituga and Tubangwa, rare Oct-Dec and common Jul-Sept, though resident in adjacent highlands. Present as summer breeder only in mountainous areas of Zimbabwe, close to border with Mozambique. Recent records from Taita Hills, in SE Kenya, where species does not breed, indicate some wandering.

Status and Conservation. Not globally threatened. Varies considerably in status throughout range. Abundant in some wet mountainous areas of E Africa, but elsewhere far more local. Scattered distribution, with numerous seemingly extralimital records, suggest range may be wider than currently thought. Reported from several protected areas, e.g. Kibale Forest National Park (Uganda), Kibira National Park (Burundi) and Nyika National Park (Malawi).

Bibliography. Benson (1952), Benson & Benson (1977), Benson *et al.* (1971), Brooke (1968, 1971a, 1971d, 1971i), Dillingham (1958), Dowsett (1977a, 1990), Dowsett & Dowsett-Lemaire (1978b, 1993), Dowsett & Forbes-Watson

(1993), Dowsett-Lemaire (1989), Duckworth *et al.* (1992), Fry *et al.* (1988), Ginn *et al.* (1989), Grant & Mackworth-Praed (1937), Harrison *et al.* (1997), Lewis & Pomeroy (1989), Lippens & Wille (1976), Mackworth-Praed & Grant (1957, 1962, 1970), Maclean (1993), Mann (1976), Newman *et al.* (1992), Nikolaus (1987), Pérez del Val (1996), Pérez del Val *et al.* (1994), Pinto (1983), Prigogine (1960, 1966), de Roo (1968), Scott (1979), Short *et al.* (1990), Snow (1978), White (1965), Williams (1980), Zimmerman, D.A. *et al.* (1996).

41. Schouteden's Swift

Schoutedenapus schoutedeni

French: Martinet de Schouteden **German:** Schoutedensegler **Spanish:** Vencejo del Congo
Other common names: Congo Swift

Taxonomy. *Apus schoutedeni* Prigogine, 1960, Butokolo, Zaire.

Genus previously merged into *Apus*; affinities uncertain. Formerly considered a race of *S. myoptilus*. Monotypic.

Distribution. E Zaire, where collected from Mubandakika, Butokolo, Bionga and Kamituga.

Descriptive notes. 16.5 cm. Small swift with structure similar to that of *S. myoptilus*; long, thin, deeply forked tail, though this probably averages shorter than in *S. myoptilus*, with less emargination in shorter outer rectrix; bulbous head and wings tapering sharply from secondaries; uniformly black-brown plumage including throat.

Habitat. Presumed to be a highland species, mainly because was collected from Butokolo at 1470 m.

Food and Feeding. Nothing known; presumably similar to congener.

Breeding. Female collected in Feb had enlarged oocytes; two specimens from Oct did not have enlarged gonads.

Movements. Not known.

Status and Conservation. **VULNERABLE.** Restricted-range species: present in Eastern Zaire Lowlands EBA. Still known from only five specimens. Habitat within species' range thought still to be in reasonably good condition; however, deterioration or loss of habitat may be greatest threat, although preferences of species still remain essentially unknown. Much research and survey work required in order to establish current status and conservation requirements.

Bibliography. Brooke (1971a, 1971d, 1971i), Collar & Andrew (1988), Collar & Stuart (1985, 1988a), Collar *et al.* (1994), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fry *et al.* (1988), Hall & Moerau (1962), Lippens & Wille (1976), Mackworth-Praed & Grant (1970), Prigogine (1960, 1971, 1978), de Roo (1968), Schouteden (1968), Snow (1978), Stattersfield *et al.* (1998), White (1965), Wilson & Catsis (1990).

Tribe CHAETURINI

Genus *MEARNSIA* Ridgway, 1911

42. Philippine Spinetail

Mearnsia picina

French: Martinet des Philippines **German:** Philippinensegler **Spanish:** Vencejo Filipino
Other common names: Philippine Needletail, Philippine Spine-tailed Swift/Needletail

Taxonomy. *Chaetura picina* Tweeddale, 1879, Zamboanga, Mindanao. Previously placed in *Chaetura*. Monotypic.

Distribution. SC & S Philippines on Leyte, Negros, Cebu, Biliran, Samar and Mindanao.

Descriptive notes. 14 cm. Large spinetail with very long wings hooked in outer wing, bulging midwing and pinched in at body; large head and relatively short, square tail, appearing more rounded when spread, rectrix spines extending up to 1.2 mm beyond web. Very black plumage broken only by small, but highly distinct, white throat-patch and equally striking white patches on underwing-coverts, last feature unique in Apodiformes.

Habitat. Apparently a forest species.

Food and Feeding. Usually seen at high elevations alone or in small groups.

Breeding. Not known.

Movements. Resident.

Status and Conservation. Not globally threatened. Restricted-range species: present in Negros and Panay EBA, Cebu EBA (extinct), Mindanao and the Eastern Visayas EBA and Sulu Archipelago EBA. Believed to be uncommon throughout range. Recorded in low numbers during 1991 survey of Negros. Occurs in Mount Canlaon National Park, Negros.

Bibliography. Brooks & Dutton (1997), Brooks, Evans *et al.* (1992), Brooks, Magsalay *et al.* (1995), Delacour & Mayr (1946), Dickinson *et al.* (1991), Evans, Dutton & Brooks (1993), Hachisuka (1934), Inskipp *et al.* (1996), Lambert (1993), McGregor (1909-1910, 1921), Rand (1951a), Stattersfield *et al.* (1998).

43. Papuan Spinetail

Mearnsia novaeguineae

French: Martinet papou **German:** Papuasegler **Spanish:** Vencejo Papú
Other common names: Papuan/New Guinea Spinetail/Spinetailed Swift/Needletail, Grey-bellied Needletail

Taxonomy. *Chaetura novaeguineae* D'Alberty and Salvadori, 1879, Fly River, New Guinea. Previously placed in *Chaetura*, and earlier in monospecific genus *Papuanapus*. Proposed race *mamberana*, known from mouth of Mamberano R, nowadays included in *buergersi*. Two subspecies currently recognized.

Subspecies and Distribution.

M. n. buergersi (Reichenow, 1917) - N New Guinea.

M. n. novaeguineae (D'Alberty & Salvadori, 1879) - S & SE New Guinea.

Descriptive notes. 11.5 cm. Small spinetail with large head, short square tail appearing rounded when spread, rectrix spines up to 1 mm beyond web, and distinct wing shape which is hooked in outer wing, has bulging midwing and then pinches in at body. Very glossy plumage, black with green sheen above; black tail and undertail-coverts; grey-brown throat with remainder of underparts strikingly white. Race *buergersi* has paler throat and relatively even whiter underparts.

Habitat. Lowland species not recorded over 550 m. Found primarily over forested areas on coast and in interior; can be recorded around

settlements. In lowland rainforest zone of Papua New Guinea recorded over forest edge and non-forest.

Food and Feeding. Typically forages in pairs or small flocks, groups over 40 not unknown. Often associates with swiftlets. Very active in crepuscular period. Feeds at low elevations, at tree height and below, particularly around dead trees. May take insects directly from foliage.

Breeding. Breeds in second half of dry season in Trans-Vanapa, Central Province. Nests in hollows in trees; recorded entering hollow trunk of burnt sago palm, 7 m high; has been recorded collecting fibres from dry palms, which it presumably uses in nest construction.

Movements. Resident; may show some local dispersal.

Status and Conservation. Not globally threatened. Frequency varies locally from scarce to abundant in suitable habitat; locally common around Kiunga, on upper Fly R. Record in 1992 of 10 birds in W Vogelkop region, where species previously unknown may suggest dispersal or perhaps some sort of range expansion.

Bibliography. Anon. (1994a), Beehler, Pratt & Zimmerman (1986), Beehler, Sengo *et al.* (1995), Burrows (1993), Coates (1977, 1985), Finch (1981), Gregory (1995a, 1995b, 1996), Hicks (1988c, 1989), Mayr & Rand (1937), Murray (1988), Rand & Gilliard (1967), Ripley (1964a).

Genus *ZOONAVENA* Mathews, 1918

44. Madagascar Spinetail

Zoonavena grandidieri

French: Martinet de Grandidier **German:** Malegassensegler **Spanish:** Vencejo Malgache
Other common names: Madagascar Spine-tailed Swift, Malagasy Spinetail/Needletail

Taxonomy. *Chaetura grandidieri* J. Verreaux, 1867, Mandrisis, eastern Madagascar.

Previously placed in *Chaetura*. Two subspecies recognized.

Subspecies and Distribution.

Z. g. grandidieri (J. Verreaux, 1867) - Madagascar.

Z. g. mariae (Benson, 1960) - Grand Comoro (Ngazidja) in Comoro Is.

Descriptive notes. 12 cm. Small spinetail with typical wing shape, hooked in outer wing and bulging in midwing; square tail appears slightly cleft in some views and rounded when spread, rectrix spines extending up to 3 mm and 1.5 mm respectively in those male and females measured. Black-brown upperparts broken by heavy streaked white rump; rather uniform pale grey-brown underbody. Race *mariae* averages shorter-winged and has darker rump.

Habitat. Essentially a forest species. In Madagascar occurs over wide range of habitats, particularly with very large trees, but also over paddies, mainly in lowlands to 1000 m though

found to 1400 m in Marojejy reserve. On Grand Comoro infrequent away from forest, at 400-1750 m, less often at lower altitudes right down to sea-level.

Food and Feeding. Insects. Forages low over canopy or between trees close to ground, alone or in pairs or small flocks, up to 15 recorded together.

Breeding. Season thought to be Apr-Jan, though birds with enlarged gonads have been collected in Jul, Aug, Sept, Oct, Jan, Mar and May, indicating year-round breeding; aerial copulation reported mid-Sept. Nests in various holes such as tree hollows, rock niches and wells; nest composed of various vegetable matter including twigs.

Movements. Resident.

Status and Conservation. Not globally threatened. Rather common, especially in moister E areas of Madagascar. Occurs in Perinet Special Reserve, c. 150 km E of Antananarivo. Widespread in suitable habitat on Grand Comoro, but numbers generally low, and rare at some sites, such as La Grille.

Bibliography. Appert (1972, 1996), Benson (1960), Benson *et al.* (1976-1977), Brooke (1971), Dee (1986), Delacour (1930), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Garino (1996), Langrand (1994, 1995), Lavauden (1937), Louette (1988a), Louette & Stevens (1992), Louette *et al.* (1988), Milon *et al.* (1973), Morris & Hawkins (1998), Rand (1936), Safford & Duckworth (1990), Sinclair & Langrand (1998), Snow (1978), Stevens, Herremans & Louette (1992), Stevens, Louette *et al.* (1995), Thompson & Buisson (1988), Thorstorn & Watson (1997).

45. Sao Tome Spinetail

Zoonavena thomensis

French: Martinet de Sao Tomé **German:** Sao-Tomé-Segler **Spanish:** Vencejo de Santo Tomé
Other common names: Sao Tome Spine-tailed Swift

Taxonomy. *Chaetura thomensis* Hartert, 1900, São Tomé.

Previously placed in *Chaetura*. In past, considered possibly conspecific with *Rhaphidura sabini*, but this view now unanimously rejected. Monotypic.

Distribution. São Tomé and Príncipe, in Gulf of Guinea.

Descriptive notes. 10 cm; c. 8 g. A tiny spinetail with typical spinetail wing shape, hooked in outer wing with bulging midwing, and square tail, appearing rounded when spread, rectrix spines 1.2-2.5 mm beyond web. Black-brown upperparts broken by broad pale rump-band; brown throat indistinctly separated from heavily streaked off-white underparts.

Habitat. Essentially a forest species, primary or secondary, but also over adjacent cultivated areas and plantations. Found from lowland to 1500 m on São Tomé, mainly at 200-800 m in E and between sea-level and 400 m in W, and to 500 m on Príncipe. Apparently avoids *Apus*

affinis, which occupies low elevations, in E São Tomé, but forms mixed flocks with this species on Príncipe and nearby Prince I.

Food and Feeding. Insects, including tiny beetles. Forages in groups of 8-10, circling trees and also performing "figures of eight" 5-10 m above ground.

Breeding. Inferred egg-laying in early Aug and late Oct on São Tomé, and in Sept on Príncipe. Solitary nester. Open, cupped, nest structure, 15-25 mm long, stuck to vertical side of hollow tree, e.g. silk-cotton (*Ceiba pentandra*), 3 m above floor or lower, 20-40 cm above ground when among buttress roots; old nests found in hollows presumed to be previous season's nest of active pair. Clutch 2-3, sometimes 4.

Movements. Resident.

Status and Conservation. Not globally threatened. Restricted-range species: present in São Tomé EBA and Príncipe EBA. Common on both islands.

On following pages: 46. White-rumped Spinetail (*Zoonavena sylvatica*); 47. Mottled Spinetail (*Telecanthura ussheri*); 48. Black Spinetail (*Telecanthura melanopygia*); 49. Silver-rumped Spinetail (*Rhaphidura leucopygialis*); 50. Sabine's Spinetail (*Rhaphidura sabini*); 51. Cassin's Spinetail (*Neorapapap cassinii*); 52. Böhm's Spinetail (*Neorapapap boehmi*); 53. White-throated Needletail (*Hirundapus caudacutus*); 54. Silver-backed Needletail (*Hirundapus cochinchinensis*); 55. Brown-backed Needletail (*Hirundapus giganteus*); 56. Purple Needletail (*Hirundapus celebensis*).

Bibliography. Amadon (1953), Atkinson, Dutton *et al.* (1994), Atkinson, Peet & Alexander (1991), Christy (1998), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Frade (1958), Fry *et al.* (1988), Garino (1996), Jones & Tye (1988), Mackworth-Præd & Grant (1970), de Naurois (1985, 1994b), Sargeant (1992a, 1994c), Snow (1950, 1978), Stattersfield *et al.* (1998).

46. White-rumped Spinetail

Zoonavena sylvatica

French: Martinet indien **German:** Hindusegler **Spanish:** Vencejo Indio
Other common names: Indian White-rumped Spinetail/Spine-tailed Swift, White-rumped Needletail

Taxonomy. *Acanthylis sylvatica* Tickell, 1846, central India. Previously placed in *Chaetura*. Monotypic.

Distribution. S of Himalayas from NC India (N Uttar Pradesh) and Nepal S through E & EC India, and E to W Myanmar, where status uncertain; also S through Western Ghats to S Kerala.

Descriptive notes. 11 cm; 13 g. Small spinetail with short square tail, rounded when spread, relatively large head and distinctive wing shape, hooked outer wing, bulging midwing and pinched in at body; rectrix spines up to 4 mm beyond webs. Blackish upperparts broken by white rump-band which is contiguous with white underparts that contrast with indistinct grey throat.

Habitat. In Himalayas found to 1770 m, though generally at lower altitudes over variety of forest types, including plantations.

Food and Feeding. Mainly Coleoptera and Hemiptera. Usually forages in small groups,

though up to 50 have been recorded together, over forested and adjacent habitats.

Breeding. Season mainly Mar-Apr, though recorded Feb-May, Western Ghats. Believed to be a solitary breeder; multiple nests at some sites suggest new nests are used in traditional sites. Nests are depressions lined with dry leaves and straw, in debris at base of hollow trunks in old humid forest trees. Clutch 3-4, occasionally 5.

Movements. Largely resident, but with some dispersal, which appears to be without pattern.

Status and Conservation. Not globally threatened. Generally rather local and uncommon, but sometimes abundant; groups of up to 50 individuals occasionally recorded, but numbers are normally much lower. In Nepal, local and uncommon, though seen with some regularity at Chitwan National Park. Occurs in several protected areas in India, e.g. Corbett, Indira Gandhi and Periyar National Parks.

Bibliography. Ali (1935-1937), Ali & Grubb (1976), Ali & Ripley (1983), Anon. (1994b), Daniels (1997), Grimmett *et al.* (1998), Inskipp, C. & Inskipp (1991), Inskipp, T. *et al.* (1996), Javed & Rahmani (1998), Kannan (1998), Ripley (1982), Stewart (1913), Sugathan & Varghese (1996).

Genus *TELECANTHURA* Mathews, 1918

47. Mottled Spinetail

Telecanthura ussheri

French: Martinet d'Ussher **German:** Baobabssegler **Spanish:** Vencejo de Baobab
Other common names: Ussher's/Mottled-throated Spinetail/Spinetailed Swift

Taxonomy. *Chetura ussheri* Sharpe, 1870, Ghana.

Genus formerly merged into *Chaetura*, or occasionally *Rhaphidura*. It has been suggested that present species may be better treated as two due to differences in plumage, structure and habitat, though precise situation of dividing line unclear. Proposed race *marwitzi* of Wemberere steppe, Tanzania, known only from type, and believed to represent aberrant individual of race *stictilaema*. Four subspecies currently recognized.

Subspecies and Distribution.

T. u. ussheri (Sharpe, 1870) - broken range from Senegambia to Nigeria.

T. u. sharpei (Neumann, 1908) - Cameroon to Gabon, and Zaire E to Uganda.

T. u. stictilaema (Reichenow, 1879) - CE Africa, and recently also Zanzibar and Pemba I.

T. u. benguellensis (Neumann, 1908) - W Angola and SE Africa.

Descriptive notes. 14 cm; male 33 g, female 34-5 g. Medium-sized spinetail with typical spinetail "butter-knife" wing shape, with hooked outer wing, bulging inner primaries and outer secondaries and pinched in at body; prominent tail, appearing rounded when spread and square when closed, rectrix spines 2-4 mm beyond web; large head; pale-mottled throat and white rump and ventral area on otherwise black-brown upperparts and underparts. Race *sharpei* is blackest subspecies, with browner throat-patch and longer tail than nominate; *stictilaema* blacker than nominate with shorter wings and longer tail; *benguellensis* is brown-

est race, with browner throat and greyer underparts, white ventral patch less contrasting.

Habitat. A lowland species over much of range, though recorded to 2200 m in E Africa and 900 m in Zambia. Found over variety of habitats, including gallery forest and clearings in evergreen forest, generally avoiding human habitation. Preferred habitat appears to be dry deciduous woodland dominated by baobabs (*Adansonia digitata*). Shows preference for coastal zone in Senegal, parts of E Africa and Angola. In Ivory Coast prefers *Borassus* palm savanna. Racial preferences in habitat: nominate form in deciduous forest and occasionally in upper Guinea forest types; *sharpei* in evergreen forest; *stictilaema* in dry deciduous and less frequently evergreen forest; *benguellensis* more often in woodland than forest.

Food and Feeding. Winged ants and small numbers of flies, termites and Hymenoptera. Highly mobile when foraging and often seen only fleetingly. Typically in pairs or small groups, though an exceptional flock of 100 recorded. Associates with other swifts and hirundines.

Breeding. Breeds Transvaal Apr-May; enlarged gonads Zaire Jan and Jul-Aug, Cameroon Feb, Kenya Feb and Apr, Uganda Mar and Sept; copulation Tanzania Dec; laying Cameroon Jan-Mar, Babonde, Zaire, Jun; nestlings Ghana Mar, Zaire Apr-May and Aug-Sept, Cameroon May-Jun and Oct. Solitary. Nests in hollow trees, especially baobabs; also in chimney stacks, on walls or under beams of houses; uses new nest in each breeding season as up to 4-5 old nests noted in a hollow. Salivary glands enlarged in both sexes, suggesting both build; strong bracket-shaped nest of dry twigs typically 2 cm long and other vegetable matter, agglutinated with saliva, with curtain of twigs hanging below structure; whole structure measures 75-80 mm at point of attachment. Copulates in flight. 4 eggs.

Movements. Resident throughout much of range, yet some seasonal movements recorded. Occurs in SW Mt Kenya during Sept-Jan, and absent from Mampong, Ghana, Sept-Jan, where frequent Feb-Jun and common Mar-May during breeding season.

Status and Conservation. Not globally threatened. Status varies throughout range. Most abundant in parts of E & C Africa, rarest in limited S African range, where it is thought that protection of baobab habitats will give it a secure future. In 1984, South Africa was believed to hold fewer than 50 pairs, though perhaps as many as 300 individuals; classified as Red Data Species for the country; recently, regularly recorded in N sector of Kruger National Park. Also believed to be rarest Liberian spinetail, though status there uncertain; only handful of records from Sierra Leone. Considered uncommon throughout Kenyan range but can be recorded daily in reasonable numbers, in summer at least, along coastal strip. Occurs in a number of protected areas across its sizeable range, e.g. Niokola Koba National Park (Senegal) and Mikumi National Park (Tanzania).

Bibliography. Anon. (1998b), Archer & Iles (1998), Archer & Turner (1993), Ash & Miskell (1998), Barlow *et al.* (1997), Benson (1977), Benson & Benson (1977), Benson & Winterbottom (1977), Benson *et al.* (1971), Brooke (1968, 1971c, 1971e, 1971i, 1984), Chantler & Driessens (1995b), Chapin (1939), Cheke & Walsh (1996), Clancey (1968), Colston & Curry-Lindahl (1986), Dowsett (1989a), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Elgood *et al.* (1994), Field (1998), Friedmann (1930), Fry *et al.* (1988), Garino (1996), Gatter (1988, 1997), Ginn *et al.* (1989), Gore (1990), Grant & Mackworth-Præd (1937), Grimes (1972, 1987), Harrison *et al.* (1997), Heigham & Ryder (1981), Lewis & Pomeroy (1989), Lippens & Wille (1976), Louette (1981), Mackworth-Præd & Grant (1937, 1957, 1962, 1970), Maclean (1993), Moreau & Moreau (1937), Newman *et al.* (1992), Pinto (1983), Serie *et al.* (1977), Short *et al.* (1990), Snow (1978), Williams (1980), Zimmerman, D.A. *et al.* (1996).

48. Black Spinetail

Telecanthura melanopygia

French: Martinet de Chapin **German:** Iturisegler **Spanish:** Vencejo del Ituri
Other common names: Chapin's Spinetail, Ituri (Mottled-throated) Spinetail/Spinetailed Swift

Taxonomy. *Chaetura melanopygia* Chapin, 1915, Avakubi, Ituri District, Zaire.

Genus formerly merged into *Chaetura*, or occasionally *Rhaphidura*. Monotypic.

Distribution. Sierra Leone to S Ghana, Nigeria, Cameroon and Gabon; also SW Central African Republic, NE Zaire and NE Angola.

Descriptive notes. 15 cm; 52 g. Large, slender spinetail with long wings, typical hooked outer primaries, bulging inner primaries and outer secondaries, pinched in at body; prominent tail appears rounded when spread and square when closed; rectrix spines up to 6 mm beyond web. Dark black-brown, especially above, broken only by underwing contrast and paler mottling on throat.

Habitat. Rainforest zone over a variety of habitats, including primary and secondary forest, plantations and rocky outcrops.

Food and Feeding. Winged ants reported from 1 stomach. Generally a low-elevation feeder

that freely associates with other swifts and also Square-tailed Saw-wing (*Psilidoprocne nitens*). Seen singly or in groups of up to 12.

Breeding. Largely unknown. Enlarged gonads in Ghana in Feb, and Zaire in Oct; entering tree hollows in Liberia late Dec to mid-Mar, where aerial copulation mid-Dec and late Jan. Possibly nests in crags rising above forest.

Movements. Generally considered resident. Some authors have suggested that this may be an afrotropical migrant, although it has been speculated that it may just wander considerable distances over suitable habitat. Migrates from Liberia in rainy season.

Status and Conservation. Not globally threatened. Locally uncommon to rare throughout, but believed to occur more widely than present knowledge indicates, and certainly overlooked. Some evidence that it occurs in higher densities in Liberia since fragmentation of habitat. Report of 60 birds at 1 site in SW Ghana in Sept 1989. Occurs in Gola Forest Reserves (Sierra Leone), Tai Forest National Park (Ivory Coast) and Korup National Park (Cameroon).

Bibliography. Allport *et al.* (1989), Anon. (1998b), Brooke (1971i), Brosset & Éard (1986), Carroll (1988), Chapin (1939), Cheke & Walsh (1996), Colston & Curry-Lindahl (1986), Deme & Fishpool (1991, 1994), Dowsett & Dowsett-Lemaire (1993, 1997), Dowsett & Forbes-Watson (1993), Elgood *et al.* (1994), Field (1998), Fry *et al.* (1988), Garino (1996), Gatter (1988, 1997), Green & Carroll (1991), Green & Rodewald (1996), Grimes (1987), Heim de Balsac & Brosset (1964), Lippens & Wille (1976), Lockwood *et al.* (1980), Louette (1981), Mackworth-Præd & Grant (1970), Pinto (1983), Rodewald *et al.* (1994), Snow (1978), Thiollay (1985), Traylor (1963).

Genus *RHAPHIDURA* Oates, 1883

49. Silver-rumped Spinetail

Rhaphidura leucopygialis

French: Martinet leucopyge **German:** Silberbüzelssegler **Spanish:** Vencejo Cutiplata
Other common names: Silver-rumped (Spine-tailed) Swift, Silver-rumped Needletail, White-rumped Spinetail(!)

Taxonomy. *Acanthylis leucopygialis* Blyth, 1849, Penang.

Genus formerly merged into *Chaetura*. Monotypic.

Distribution. S Myanmar to Malay Peninsula, Sumatra, and Bangka I, Borneo and Java.

Descriptive notes. 11 cm. Small spinetail with typical wing shape, hooked outer wing, bulging midwing, sharply pinched in at body; protruding head and square tail, appearing rounded when spread, rectrix spines up to 4 mm beyond web. Very black plumage with sharply contrasting white rump and uppertail-coverts, actually grey-tinged with shaft streaking at close range.

Habitat. Mainly lowlands to 600 m in Sumatra, 1500 m in Java and 1250 m in Malay Peninsula. Occurs over forests, primary and secondary growth, and plantations often close to water, including estuarine habitats where more regular than over fresh water in one Sarawak study.

Infrequent near human settlements.

Food and Feeding. Forages around clearings or rock outcrops in forest. Malaysian study noted larger numbers feeding over forested areas and mainly in higher strata, over 30 m, though lower than other high-elevation group feeders - *Hirundapus*, *Apus pacificus* and *A. affinis*. Mean foraging height lower over forested areas than elsewhere (40 m as compared to 43 m) and 31% of foraging occurs within 10 m of vegetation. Especially active in evening. Not often seen with other species and rarely in groups of more than 6.

Breeding. Little studied. During May-Jun several birds were thought to be nesting in a hollow tree in Borneo, possibly colonially. Nests in hollow trees.

Movements. Resident.

Status and Conservation. Not globally threatened. Locally common in suitable habitat, though uncommon in Java. During major study of aerial feeding in W Malaysia, this was least frequently encountered of all identified swift species. Occurs in many protected areas, e.g. Taman Negara National Park (Malaysia), Way Kambas National Park (Sumatra), Gunung Mulu and Bako National Parks (Sarawak), and Khao Nor Chuchi Non-hunting Area (Thailand).

Bibliography. Davison (1995, 1997a, 1997b), Duckworth & Kelsch (1988), Inskipp *et al.* (1996), Lekagui & Round (1991), MacKinnon (1988), MacKinnon & Phillips (1993), van Marle & Voous (1988), Medway & Wells (1976), Meyer de Schauensee & Ripley (1940), Nash & Nash (1988), Parrott & Andrew (1996), Rajathurai (1996), Riley (1938), Smith (1977), Smythies (1981, 1986), Vowles & Vowles (1984), Waugh & Hails (1983), Wells (1999), Wilkinson *et al.* (1991).

50. Sabine's Spinetail

Rhaphidura sabini

French: Martinet de Sabine

German: Sumpfsegler

Spanish: Vencejo de Sabine

Other common names: Sabine's Spine-tailed Swift

Taxonomy. *Chaetura Sabini* J. E. Gray, 1829, Sierra Leone.

Genus formerly merged into *Chaetura*. Has been considered possibly conspecific with *Zoonavena thomensis*, but this view has not gained support and is contradicted by considerable dissimilarities. Birds of R Ogowe (Gabon) previously recognized as race *ogowensis*, by virtue of alleged smaller size. Monotypic.

Distribution. Broken range from S Guinea to NW Gabon and coastal & C Congo, then through NW & E Zaire and S Central African Republic to W Uganda; isolated population in W Kenya.

Descriptive notes. 11-5 cm; average male 20 g, female 19 g. Small, elegant spinetail with relatively large head and distinctive wing shape, hooked outer wing, bulging midwing and pinched in at body; short square tail, appearing rounded when spread, rectrix spines up to 4 mm beyond web. Blackish upperparts broken by broad white band on rump and uppertail-coverts, contiguous with white underparts which contrast strongly with black upper breast and throat; white areas of plumage faintly dark-streaked.

Habitat. A rainforest species typically found at 700-1700 m, though also in lowlands, around

forest edges and clearings but also over nearby grasslands and even mangroves. Often close to water; freshwater riverine swamps with very large solitary trees and low vegetation thought to be optimum habitat in Liberia, along with border zone between forest and montane savannas.

Food and Feeding. Flying and wingless ants, flies, small beetles, and insects resembling mosquitoes recorded. Typically seen close to ground, but sometimes at great height over canopy.

Breeding. Probably breeding Liberia Mar, Apr and Sept; enlarged gonads Liberia Mar-Apr, Cameroon May, Kenya and Zaire Jun; egg-laying Cameroon Mar and probably May; nestlings Kenya Jan or Feb, Zaire Jun and Aug. Nests singly or 2 pairs together in tree hollows or niches among large tree roots; probably within suitable man-made structures on occasions. Small half-cupped nest of twigs attached to vertical surface. Clutch 2-3.

Movements. Believed resident throughout much of range, though data from Liberia suggest it is a partial migrant there.

Status and Conservation. Not globally threatened. Fairly common to common. Least abundant in tiny W Kenyan range, where perhaps some decline in 20th century, as indicated by paucity of recent records. Current density in Liberia perhaps greater than it was before forest fragmentation, as species will occupy secondary habitats. Not uncommon in Ghana, where is commonest spinetail in Bia National Park. In Sierra Leone, common in all of the larger forests. In Cameroon, occurs on Mt Cameroon and Mt Kupé; also found on Mt Nimba, Liberia, and in Tai Forest National Park.

Bibliography. Allport *et al.* (1989), Bannerman (1933), Bates (1911, 1930), Britton (1970), Brooke (1971c, 1971i), Carroll (1988), Cheke & Walsh (1996), Christy & Clarke (1994), Colston & Curry-Lindahl (1986), Demey & Fishpool (1991, 1994), Dowsett (1989b), Dowsett & Dowsett-Lemaire (1991, 1993, 1997), Dowsett & Forbes-Watson (1993), Elgood *et al.* (1994), Field (1974, 1998), Fry *et al.* (1988), Garino (1996), Gatter (1988, 1997), Germain & Cornet (1994), Gore (1994), Green & Carroll (1991), Grimes (1987), Halleux (1994), Lewis & Pomeroy (1989), Lippens & Wille (1976), Louette (1981), Mackworth-Præd & Grant (1957, 1970), Mann (1976), Pérez del Val (1996), Pinto (1983), Rodewald *et al.* (1994), Serle *et al.* (1977), Short *et al.* (1990), Snow (1978), Thiollay (1985), Traylor (1963), Williams (1960, 1980), Wilson (1990), Zimmerman, D.A. *et al.* (1996).

Genus NEAFRAPUS Mathews, 1918

51. Cassin's Spinetail

Neafrapus cassini

French: Martinet de Cassin

German: Cassinsegler

Spanish: Vencejo de Cassin

Other common names: Cassin's Spine-tailed Swift

Taxonomy. *Chaetura cassini* P. L. Selater, 1863, Gabon.

Genus formerly merged with *Chaetura* or *Mearnsia*. Race *brevicauda* of Bipindi (Cameroon) has been recognized but consistent geographical variation is lacking in this species. Monotypic.

Distribution. E Sierra Leone and Liberia to Ghana, and SW Nigeria to Cabinda (extreme N Angola); Bioko I; also extreme E Congo through N Zaire and SW Central African Republic to W Uganda.

Descriptive notes. 15 cm; 39.5 g. Large spinetail with remarkably short, square tail with rectrix spines up to 6 mm beyond webs, large bulging head, long-winged appearance and typical spinetail wing shape, with especially bulging secondaries and hooked outer wing. Black-brown upperparts broken by narrow white rump band; grey throat and black flanks, especially noticeable on rear flanks, contrast with lightly streaked white underparts.

Habitat. Restricted to rainforest zone, where forest lakes seem to be preferred habitat to feed over. Adjoining secondary growth and plantations sometimes visited. Original habitat

intraforest riverine swamps with large trees, but increasingly occupies forest edge and clearings near water.

Food and Feeding. Flying ants and smaller numbers of termites and small beetles recorded; also 200 leafhoppers (Cicadellidae) and 100 termites in 1 stomach. During day often feeds at great height, while crepuscular feeding usually at low level. Often with sympatric spinetails, especially *Rhaphidura sabini*. Gregarious, up to 40 recorded together, though smaller flocks more typical.

Breeding. Although not proven, considerable circumstantial evidence points to nesting in hollow trees; no nest found to date. Enlarged gonads on Bioko Jul, in Zaire Jul, Sept and Nov; flights and tree hollow visits Liberia Feb-Apr; postulated laying dates in Zaire Apr and Jul, Gabon c. Aug-Sept; watched leaving hollow tree with feathers belonging to this species at base, with eggshell, Avakubi, Zaire, Apr; believed to be feeding young in hollow stump Zaire, Jul, and among cavities in dead trees Gabon, Oct. No further information available.

Movements. Resident throughout much of range, but Liberian data suggest some migration with absence during rains in SE. May be transequatorial migrant.

Status and Conservation. Not globally threatened. Uncommon throughout most of range. In Liberia, where uncommon, found in all studied forests, usually in groups of 5 birds or fewer though up to 15 individuals sometimes recorded. Uncommon in Ghana, where not recorded until 1960's, though uncertain whether this reflects range expansion or that species was previously overlooked; recorded in Bia National Park and Subri River Forest Reserve. In Sierra Leone, known only from environs of Gola Forest, where only recently found to occur. Occurs in Tai Forest National Park.

Bibliography. Amadon (1953), Bannerman (1953), Brooke (1971c, 1971i), Chapin (1939), Cheke & Walsh (1996), Christy & Clarke (1994), Colston & Curry-Lindahl (1986), Dowsett & Dowsett-Lemaire (1991, 1993), Dowsett & Forbes-Watson (1993), Eiseutraut (1973), Elgood *et al.* (1994), Field (1998), Fry *et al.* (1988), Garino (1996), Gatter (1997), Green & Carroll (1991), Grimes (1987), Keith (1968), Lippens & Wille (1976), Louette (1981), Mackworth-Præd & Grant (1970), Pérez del Val (1996), Pérez del Val *et al.* (1997), Pinto (1983), Serle *et al.* (1977), Short *et al.* (1990), Snow (1978), Sutton (1965), Traylor (1963), Wells (1968).

52. Böhm's Spinetail

Neafrapus boehmi

French: Martinet de Böhm

German: Fledermaussegler

Spanish: Vencejo de Böhm

Other common names: Böhm's Spine-tailed Swift, Bat-like Spinetail

Taxonomy. *Chaetura Böhm* Schallow, 1882, Tanzania.

Genus formerly merged with *Chaetura* or *Mearnsia*. Intergrades between nominate race and *sheppardii* occur in upper Zambezi Valley. Two subspecies normally recognized.

Subspecies and Distribution.

N. b. boehmi (Schallow, 1882) - W & CE Angola, S Zaire, W & N Zambia and W Tanzania.

N. b. sheppardii (Roberts, 1922) - SE Kenya and E Tanzania; E & SE Zambia, N & E Zimbabwe, Mozambique and NE South Africa.

Descriptive notes. 10 cm; 14.5 g. A small spinetail with a quite remarkable appearance: large head, very short, square tail, rectrix spines up to 3.5 mm beyond webs, and long wings with hooked outer wing and deeply bulging midwing, pinched in sharply at body. Black-brown upperparts broken by broad white rump, broader than in *N. cassini*; underparts white with contrasting grey throat and black flanks. Slightly smaller race *sheppardii* has paler lower throat and more obvious shafting on underparts and white fringing to fresh rectrices.

Habitat. A lowland species, mainly below 600 m but recorded at 900 m in Zimbabwe and 1300

m in Tanzania. Frequents range of primary savanna woodlands, typically quite open, arid and deciduous, with baobab (*Adansonia digitata*), miombo and *Cryptosepalum*, as well as edges and clearings in denser evergreen forest, both gallery and larger expanses.

Food and Feeding. Flies, beetles and ants recorded. Highly gregarious, associating with various species of saw-wing swallow (*Psittidoprocne*), *Telecanthura ussheri* and *Cypsiurus parvus*. Forages close to large trees. Noted in groups of 2-6 at Kariba, Zimbabwe, with Lesser Striped Swallows (*Hirundo abyssinica*), Wire-tailed Swallows (*H. smithii*) and *C. parvus* in lowest of 3 feeding levels,

below 20 m. This stratification apparent only when several species present; fed at other levels when alone or with just 1 other species.

Breeding. Egg-laying Kenya Jan or Feb, Tanzania Apr, Kasai, Zaire, Oct, Zambia Sept-Oct and Jan, South Africa Apr; newly fledged young Angola Feb, Zimbabwe May and Dec. Solitary, nesting exclusively in subterranean sites such as wells or pits, typically in *Brachystegia* woodland and usually 3-9 m below ground on slight overhang; new nest built every season. Nest U-shaped, of twigs 2-3 cm long with 1 or 2 feathers, measuring 60-80 mm wide × 25-65 mm deep, 3 eggs, though 2 recorded; parent incubates facing wall; estimated incubation 14 days; young fully feathered at 3 weeks, some leaving nest at 4 weeks and clinging to adjacent wall; fly at 5-5-6 weeks. Perhaps double-brooded; females probably not sexually mature until after 2 years old.

Movements. Resident throughout range, but apparently more abundant in Zambia in dry season, while numbers reduced in Zimbabwe in middle of wet season.

Status and Conservation. Not globally threatened. Only locally common even in areas of greatest abundance, and rare through much of range. Classified as Red Data species in South Africa where thought to number less than 50 pairs in 1984; in recent times, regularly recorded in N sector of Kruger National Park. Present, in small numbers, in Lengwe National Park, Malawi. Within Kenya commonest in coastal strip.

Bibliography. Ash & Miskell (1998), Aspinwall (1980a), Benson & Benson (1977), Benson *et al.* (1971), Borrett & Brooke (1967), Brooke (1966, 1968, 1969a, 1971c, 1971i, 1984), Donnelly (1974), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fry *et al.* (1988), Garino (1996), Ginn *et al.* (1989), Harrison *et al.* (1997), Lewis & Pomeroy (1989), Lippens & Wille (1976), Mackworth-Præd & Grant (1957, 1962, 1970), Maclean (1993), Newman *et al.* (1992), Pinto (1983), Short & Horne (1985), Short *et al.* (1990), Snow (1978), Woods (1962), Zimmerman, D.A. *et al.* (1996).

Genus *HIRUNDAPUS* Hodgson, 1837

53. White-throated Needletail

Hirundapus caudacutus

French: Martinet épineux **German:** Stachelschwanzsegler **Spanish:** Vencejo Mongol
Other common names: White-throated Spinetail/Spinetailed Swift, (Northern) Spine-tailed Swift, Needle-tailed Swift, Northern Needletail

Taxonomy. *Hirundo caudacuta* Latham, 1801, New South Wales, Australia.

Genus formerly merged into *Chaetura*. Forms superspecies with *H. cochinchinensis*, with which in past sometimes considered conspecific. *H. cochinchinensis formosanus* formerly placed in present species, but has been shown to be virtually identical to nominate race of *H. cochinchinensis*, to which it clearly belongs. Two subspecies recognized.

Subspecies and Distribution.

H. c. caudacutus (Latham, 1801) - C Siberia E to Japan and Kuril Is; winters in S New Guinea and E Australia.

H. c. nudipes (Hodgson, 1837) - Himalayas, irregularly from N Pakistan E to Assam; Arunachal Pradesh through N Myanmar to SC China (Sichuan to Yunnan).

Descriptive notes. 19-20 cm; 101-140 g. Large swift with short square tail and weak, short rectrix spines protruding up to 6 mm beyond web; long full body and long broad wings; dark wings with blue gloss fading to green on remiges and coverts; off-white mantle, contrastingly white throat, white forehead, and white "horseshoe" mark on flanks and undertail-coverts on otherwise brown body. Rather variably plumaged juvenile less glossy with darker throat, less obvious mantle patch, black tips to undertail-coverts and usually dark forehead. Race *nudipes* has black forehead and lores, less distinct mantle patch and

generally darker plumage.

Habitat. In N parts of range, wooded lowlands and sparsely vegetated hills. In Himalayas at 1250-4000 m, feeding over river valleys and upland meadows and pastures, as well as subtropical, broadleaved and temperate forest between 1000-2800 m in C Bhutan. Winters in both coastal and mountainous areas. In Snowy Mts, Australia, abundant wintering over 1800 m, and common at 1530-1800 m. In Wallacea recorded from sea-level to 800 m on Sangihe, 500 m on Buru and 3000 m on Lombok, these mountains being free of snow. Recorded in low numbers over woodland in Brisbane Forest Park, Australia. In lowland rainforest zone of Papua New Guinea recorded over forest edge and non-forest.

Food and Feeding. Coleoptera, Hemiptera and Hymenoptera recorded for race *nudipes*. Wintering birds in New South Wales, Australia, recorded feeding on flying ants. Gregarious, but rarely associates with other species while foraging during breeding season.

Breeding. Gravid female *nudipes* collected in mid-Apr in N Cachar, N India; laying late May to early Jun in Siberia and Japan. Breeds Ussuriland late May to early Jun; eggs laid from mid-Jun and fledglings leave nest late Jul to early Aug. Nest consists of scrape in debris at bottom of tree hollow; 2 pairs apparently recorded prospecting old woodpecker hole in an *Acer* tree in Pakistan. Clutch 2-7; incubation begins with first egg, both sexes incubating, period 40 days, chicks blind and naked on hatching; fledging period 40-42 days.

Movements. Nominative race is a long-distance migrant. Himalayan race *nudipes* may be resident or perhaps just summer visitor; reported to appear and disappear at localities rather suddenly, making clear assessment of migratory status complicated. Nominative on Siberian breeding grounds mid-May to late Sept. L. Baikal from second half of May to late Aug; summer visitor, Japan, Apr-Sept; migrates through China, Indochina, and to lesser extent E Thailand, Wallacea and New Guinea; recorded on passage and possibly as winter visitor through Wallacea: mid-Oct, Sangihe; Oct to early Apr, Sulawesi; Oct, Taliabu (Sula Is); Nov and Feb, Buru; late Apr, Halmahera; Jan and early Apr, Lombok; late Sept, Oct and Jan, Flores; Oct, Timor; recorded from Aru in early Apr. Migrates through SE Asia Sept-Nov and winters in Australia Dec-Mar; many records of overshooting birds in New Zealand, Nov-Mar. Recorded from Cape York Peninsula, N Australia, with *Apus pacificus* in Jul, presumably non-breeding birds. In spring, recently recorded for first time on Hainan, Apr; migrates through Hong Kong mid-Mar to early May, SE Asia as late as May, and NE China in May.

Vagrant to Aleutian Is (4 records, May), Seychelles, and W & N Europe, with British and Irish records Apr-Jul and Nov; also one Nov record from Malta.

Status and Conservation. Not globally threatened. Race *nudipes* local and uncommon throughout most of range, though fairly common in C Bhutan. Nominative race becomes commoner farther E within Siberian range. Abundant in some areas of Australian winter quarters.

Bibliography. Ali & Ripley (1983), Ali *et al.* (1996), Ashburner (1985), Bailey & Sorensen (1962), Balsh (1980), Beehler, Pratt & Zimmerman (1986), Beehler, Sengo *et al.* (1995), Blackburn (1970), Blakers *et al.* (1984), Brazil (1991), Chantler (1993), Cheng Tsohsin (1987), Coates (1985), Coates & Bishop (1997), Collins & Brooke (1976), Corben *et al.* (1982), Coventry (1989), Cramp (1985), Day (1993), Dementiev & Gladkov (1951), Diamond & Bishop (1994), Driessens (1994), Dudley *et al.* (1996), Etchécopar & Hue (1978), Ferguson-Lees (1960), Flint *et al.* (1984), Gizenko (1955), Grimmett *et al.* (1998), Higgins (1999), Hudson (1968), Inskipp, C. & Inskipp (1991), Inskipp, T. *et al.* (1996), Knystautas (1993), Lekagul & Round (1991), Lepesch (1993), Lobko-Lobanovski (1956), Luleyeva (1993), MacKinnon & Philipps (1993), Medway & Wells (1976), Miller (1980), Neufeldt & Ivanov (1960), Osborne & Green (1992), Pettigrew & Wilson (1985), Quested (1980, 1982), Reilly (1991), Roberts (1991), Robson (1995b, 1997a), Robson *et al.* (1998), Rogacheva (1992), Rose (1997b), Slater (1995), Smith (1977), Smythies (1981), Snow & Perrins (1998), Stepanyan (1990), Strahan (1994), Tarburton (1993c), Tymstra *et al.* (1997), Wells (1999), White & Bruce (1986), Yamashina (1930, 1982), Zhao Zhengjie (1995).

54. Silver-backed Needletail

Hirundapus cochinchinensis

French: Martinet de Cochinchine **German:** Graukehlsegler **Spanish:** Vencejo de la Cochinchina
Other common names: White-vented/Silver-backed Spinetail/Spinetailed Swift, White-vented/Grey-throated Needletail; Rupchandi's Needletail (*rupchandi*)

Taxonomy. *Chaetura cochinchinensis* Oustalet, 1878, Saigon, Vietnam.

Genus formerly merged into *Chaetura*. Forms superspecies with *H. caudacutus*, with which in past sometimes considered conspecific. Race *rupchandi* has been listed as a megasubspecies. Race *formosanus* formerly placed in *H. caudacutus*, but has been shown to be virtually identical to nominate race of present species, to which it clearly belongs; indeed, may be better treated as synonymous with nominate, as grounds for racial split appear to be merely its isolated distribution. A single specimen from W Java, previously separated as form *ernsti* and variously treated as a distinct species or a race of *H. giganteus*, now synonymized with nominate race of present species. Three subspecies currently recognized.

Subspecies and Distribution.

H. c. rupchandi (Biswas, 1951) - C Nepal; winters W Java, Sumatra and peninsular Malaysia.

H. c. cochinchinensis (Oustalet, 1878) - NE India (Arunachal Pradesh, Assam, Meghalaya, Manipur and possibly Mizoram), N Myanmar and SC China (Hainan), and scattered localities (status unclear) in Thailand, Laos and Vietnam; winters in Thailand, Peninsular Malaysia, Sumatra and W Java.

H. c. formosanus (Yamashina, 1936) - Taiwan; wintering area unknown.

Descriptive notes. 20 cm; 76-86 g. Large swift with broad wings, short squarish tail with rectrix spines longest and strongest in centre and up to 6-5 mm beyond web, and long full body with head particularly prominent. Markings similar to *H. caudacutus*, differing in less contrasting throat-patch, usually slightly paler chest, less contrasting mantle-patch and grey-white tertial spots. Juvenile has less obvious pale saddle and some brown crescents on white areas of rear underbody. Race *rupchandi* has darker throat than nominate and slightly paler underparts, with less glossy upperparts; *formosanus* recognized

only by virtue of geographical isolation.

Habitat. To 600 m in C lowlands of Nepal, most frequently over primary forest. Winters over variety of habitats from lowlands to 3350 m, mainly in forest areas, especially close to water.

Food and Feeding. Often encountered feeding over water on newly hatched insects, frequently with *H. giganteus*. Highly mobile and often seen in small groups; up to 200 recorded together in Malaysia. Remains in an area for long only if feeding conditions very favourable.

Breeding. Nest unknown.

Movements. Poorly understood. Occurs in Malaysia late Sept to mid-Apr, with presumed migration through SE Asia Apr-May and Sept-Oct; collected at night from Fraser's Hill, W Malaysia, between late Oct and early Dec. Flocks of 20 on passage Bintan, Riau Archipelago, Strait of Malacca, late Nov, and 50-60 at lower Ketahun R, Sumatra, early Oct. Spring migration through Hong Kong late Mar to mid-May, with records from Vietnam in May.

Status and Conservation. Not globally threatened. Believed to be common in Assam Hills, otherwise status little known. Race *formosanus* said to be uncommon; nominate race rare on Hainan. Status uncertain in several areas, especially in Indochina, where many records may refer to passage birds; reported to be common in parts of SC & S Laos. Recorded in a number of protected areas, e.g. Chitwan National Park (Nepal), Khao Yai National Park (Thailand), Taman Negara National Park (Malaysia), Bukit Timah Nature Reserve (Singapore) and Nam Bai Cat Tien National Park (Vietnam).

Bibliography. Ali & Ripley (1983), Baker (1934a), Biswas (1951), Chantler (1993), Cheng Tsohsin (1987), Collins & Brooke (1976), Delacour (1947), Delacour & Jabouille (1951), Etchécopar & Hue (1978), Grimmett *et al.* (1998), Holmes (1996), Inskipp, C. & Inskipp (1991), Inskipp, T. *et al.* (1996), Lekagul & Round (1991), MacKinnon (1988), MacKinnon & Philipps (1993), van Marle & Voous (1988), Medway & Wells (1976), Mees (1971, 1973, 1985a), Parrott & Andrew (1996), Ripley (1982), Robson (1995d, 1997c), Robson *et al.* (1989), Smythies (1944), Thewlis *et al.* (1996), Vaurie (1965), Wells (1999), Zhao Zhengjie (1995).

55. Brown-backed Needletail

Hirundapus giganteus

French: Martinet géant **German:** Eilsegler **Spanish:** Vencejo Gigante
Other common names: Brown/Giant (Brown) Needletail, Brown/Brown-throated Spinetail/Spinetailed Swift

Taxonomy. *Cypselus giganteus* Temminck, 1825, Java.

Genus formerly merged into *Chaetura*. Forms superspecies with *H. celebensis*, with which in past sometimes considered conspecific. A single specimen from W Java, previously separated as form

ernsti and variously treated as a distinct species or a race of present species, now synonymized with *H. cochinchinensis cochinchinensis*. Two subspecies normally recognized.

Subspecies and Distribution.

H. g. indicus (Hume, 1873) - SW India and Sri Lanka, and Bangladesh E into SE Asia, and Andaman Is. *H. g. giganteus* (Temminck, 1825) - Malay Peninsula, Greater Sundas and Palawan (SW Philippines).

Descriptive notes. 25 cm; 123-167 g. Very large swift with broad wings, pinched in at body, broad protruding head and bulky hind-body, short tail with prominent rectrix spines protruding up to 11.5 mm beyond web in central tail; black-brown upperbody with pale brown saddle; indistinctly paler brown throat on dark brown underparts, which show distinct white horseshoe mark on undertail-coverts and rear flanks. Juvenile has narrow pale fringes to remiges and some brown crescents on horseshoe. Race *indicus* averages shorter-winged and has a whitish supraloral patch, which is somewhat reduced in juvenile.

Habitat. In Thailand over a wide range of habitats, mainly in lowlands, to 1800 m. Prefers primary forest but also seen over secondary forest, especially where lakes or rivers present. Recorded from moist deciduous forest at Mudumalai Wildlife Sanctuary, India.

Food and Feeding. Predominantly Coleoptera, Hemiptera, Orthoptera and Hymenoptera recorded for race *indicus*. Gregarious and often seen with other needletails. Forages over forest canopy and in particular takes advantage of insect hatchings over waterways and lakes.

Breeding. Season Feb-Apr, Kerala, S India. Solitary nester. No nest construction recorded, but a depression is used or made in debris at base of tree hollow and lined with dry leaves and straw, with access to hollow through natural hole or one made by woodpecker, positioned c. 15 m above ground. Clutch 3-4, occasionally 5.

Movements. Race *indicus* partial migrant, wintering in Malay Peninsula and probably Borneo; also possibly Sumatra, where present Sept-May. Nominate race resident.

Status and Conservation. Not globally threatened. Commonly encountered in suitable habitat. Deforestation with resultant loss of mature trees in which it nests indicates that populations may decline in parts of its range. Probably under-recorded in Indochina with first C Vietnamese records from N Annam in 1988 and from C Annam as recently as 1991; recently found to be common in C & S Laos, and apparently present all year round, though previously only listed for the NE of the country. Recorded in a number of protected areas, e.g. Indira Gandhi National Park (India), Khao Yai National Park (Thailand), Taman Negara National Park (Malaysia) and Cuc Phuong National Park (Vietnam).

Bibliography. Ali (1953), Ali & Ripley (1983), Baker (1934a), Bangs & Van Tyne (1931), Chakravarthy & Purna Chandra Tejasvi (1992), Chantler (1993), Collins & Brooke (1976), Daniels (1997), Davison (1992), Deignan (1945), Dickinson *et al.* (1991), Duckworth & Kelsh (1988), Grimmett *et al.* (1998), Henry (1998), Holmes (1996), Inskipp *et al.* (1996), Kannan (1998), Lekagul & Round (1991), MacKinnon & Phillips (1993), van Marle & Voous (1988), Medway & Wells (1976), Parrott & Andrew (1996), Phillips (1978), Primrose (1921), Riley (1938),

Robson, Eames, Nguyen Cu & Truong Van La (1993), Robson, Eames, Wolstencroft *et al.* (1989), Round (1988), Smith (1977), Smythies (1981, 1986), Stewart (1913), Thewlis *et al.* (1996), Tikader (1984), Wells (1999).

56. Purple Needletail

Hirundapus celebensis

French: Martinet des Célèbes

German: Purpursegler

Spanish: Vencejo de Célebes

Other common names: Celebes Needletail, Sulawesi Spinetail/Spinetailed Swift

Taxonomy. *Chaetura gigantea* var. *celebensis* P. L. Sclater, 1865, Menado, Sulawesi.

Genus formerly merged into *Chaetura*. Forms superspecies with *H. giganteus*, with which in past sometimes considered conspecific. Some authors divide population into races *celebensis* (Sulawesi) and *dubius* (Philippines); a further body of opinion recognizes additional race *manobo* (Mindanao, Basilan, Negros). Monotypic.

Distribution. N Sulawesi and N & E Philippines (absent from Palawan).

Descriptive notes. 25 cm; 170-203 g. Very large swift with long, broad wings pinched in sharply at body, protruding head and bulky rear body; short tail with rectrix spines up to 4.5 mm beyond web in central tail; black plumage with purple gloss, uniform across body, except white supraloral patch and white horseshoe mark on rear flanks and undertail-coverts. Juvenile has dull brown supraloral patch and dull brown fringes to greater underwing-coverts.

Habitat. Occurs over open country and forests in hills and lowlands. In Sulawesi recorded at 150-2000 m.

Food and Feeding. Recorded taking large

numbers of bees from close to hives in Philippines.

Breeding. Not known.

Movements. Presumed resident. May be locally nomadic on Sulawesi.

Status and Conservation. Not globally threatened. Lack of museum specimens suggests scarcity. Large flocks of a species of *Hirundapus* recorded in C Sulawesi were presumably this species, which is generally uncommon but locally numerous in Sulawesi. In Philippines, observations from 1969 indicate heavy human persecution due to species' propensity for feeding on bees close to hives, though seen in good numbers on Negros in 1991. Occurs in Lore Lindu National Park (Sulawesi) and Mount Canlaon National Park (Philippines).

Bibliography. Andrew & Holmes (1990), Brooks & Dutson (1997), Brooks, Evans *et al.* (1992), Brooks, Magsalay *et al.* (1995), Coates & Bishop (1997), Collins & Brooke (1976), Danielsen *et al.* (1994), Delacour & Mayr (1946), Dickinson *et al.* (1991), Dutson *et al.* (1992), Evans, Dutson & Brooks (1993), Holmes & Philipps (1996), Inskipp *et al.* (1996), Mees (1985a), Morse & Laigo (1969), Rozendaal & Dekker (1989), Watling (1983), White & Bruce (1986).

PLATE 41

Family APODIDAE (SWIFTS) SPECIES ACCOUNTS

Genus *CHAETURA* Stephens, 1826

57. Band-rumped Swift

Chaetura spinicauda

French: Martinet spinicaude German: Dornensegler Spanish: Vencejo Lomiblanco
Other common names: Smoky Swift (*fumosa*)

Taxonomy. *Cypselus spinicaudus* Temminck, 1839, Cayenne. Formerly placed in genus *Acanthylis* with following three species. Race *fumosa* previously given species status. Five subspecies currently recognized.

Subspecies and Distribution.

- C. s. fumosa* Salvin, 1870 - Costa Rica, W Panama and N Colombia.
- C. s. aetherodroma* Wetmore, 1951 - E Panama to S Ecuador.
- C. s. spinicauda* (Temminck, 1839) - E Venezuela, the Guianas and N Brazil (N Amapá).
- C. s. latirostris* Zimmer & Phelps, 1952 - S Venezuela to Brazilian border and Delta Amacuro.
- C. s. aethalea* Todd, 1937 - C Brazil.

Descriptive notes. 10.5 cm; 16 g. Smallish swift with short square tail, rectrix spines up to 5 mm beyond web; protruding head; typical wing shape for genus with hooked wing-tips and broad midwing pinched in at body. Black-brown upperparts with contrastingly white rump band; uniformly dark underparts with throat slightly paler. Race *fumosa* darker with more distinct pale throat and larger, greyer rump patch; *aetherodroma* similar to latter but smaller; *latirostris* darker than nominate but paler below than last two races, with diagnostic large broad bill with more gently curved culmen; *aethalea* larger and darker with

broader, greyer rump and more pronounced throat patch.

Habitat. Main habitats defined as edge of lowland tropical evergreen forest and secondary forest. Occurs over a wide altitudinal range from sea-level to 1500 m, but in W Andes more restricted to montane sites at and above 300 m. In Amazonia over both lowland and highland forests and cleared areas, but N of Orinoco in Venezuela only over open habitats, down to sea-level.

Food and Feeding. Often feeds in crepuscular period over water. Single-species flocks most frequent at higher altitude. Forms feeding flocks with *C. cinereiventris*, *Cypseloides rutilus* and *Panyptila*

cayennensis, occurring primarily in lower strata of mixed flocks. Wet-season Panama study showed that Diptera, Hymenoptera and Coleoptera predominated with lesser numbers, less than 5% of total diet, of Hemiptera (Heteroptera and Homoptera) and a single spider. Sometimes takes insects and spiders from outer branches of trees by hovering briefly.

Breeding. Feb-Jun on Trinidad; in breeding condition on lower R Cauca, Colombia, in Mar; aerial copulation and birds in breeding condition in Panama Feb-Mar. On Trinidad nests in hollow trees.

Movements. Resident.

Status and Conservation. Not globally threatened. Often commonest *Chaetura* in areas of intrageneric sympatry. Considered most abundant swift in lowland Costa Rica and S Venezuela; recorded as common to uncommon in Ecuador. Present in many protected areas, e.g. Corcovado National Park and Carara Biological Reserve (Costa Rica), Río Nambí National Reserve (Colombia), Cueva del Guácharo National Park and Imataca Forest Reserve (Venezuela), Asa Wright Nature Centre (Trinidad).

Bibliography. Boesman (1998), de Carvalho (1961), Chantler (1995b), Chapman (1917), Dick *et al.* (1984), Friedmann (1948), Haverschmidt & Mees (1994), Herklots (1961), Hespénheide (1975), Hilty & Brown (1986), Marín (1993), Marín *et al.* (1992), Meyer de Schauensee & Phelps (1978), Peres & Whittaker (1991), Ridgely & Gwynne (1989), Ridgway (1911), Rogers (1939a), Salaman & Gandy (1994), Sick (1993, 1997), Slud (1964), Snow (1962a), Snyder (1966), Stiles & Skutch (1989), Stotz *et al.* (1996), Teixeira *et al.* (1986), Todd (1937b), Wetmore (1968a), Zimmer & Phelps (1952).

58. Lesser Antillean Swift

Chaetura martinica

French: Martinet chiquesol **German:** Antillensegler **Spanish:** Vencejo de Martinica

Taxonomy. *Hirundo martinica* Hermann, 1783, Martinique.

Forms superspecies with *C. cinereiventris* and *C. egregia*, and these three previously placed in genus *Acanthylis* along with *C. spinicauda*. Monotypic.

Distribution. Lesser Antilles, on Guadeloupe, Dominica, Martinique, St Lucia and St Vincent.

Descriptive notes. 10.5 cm. Smallish swift with short square tail, rectrix spines up to 5 mm beyond web, protruding head and distinctive wing shape, with hooked outer wing, bulging midwing and cutting in at body. Black-brown upperparts with narrow grey rump-band; brown underparts with indistinctly paler throat.

Habitat. Main habitats defined as tropical lowland evergreen forest and probably secondary forest. Seen over a variety of open and wooded habitats but mainly a forest species, in both lowland and hilly areas.

Food and Feeding. Gregarious forager, typically in flocks of 20-40, often with hirundines.

Breeding. Season believed to be late spring to early summer. Nest believed to be half-cupped; presumably nest-sites typical of genus, though 1 nest recorded in disused oven. 3 eggs.

Movements. Generally resident. Recorded as a vagrant to Nevis. Erroneous record from Trinidad.

Status and Conservation. Not globally threatened. Restricted-range species: present in Lesser Antilles EBA. Fairly common on Dominica, Martinique, St Lucia and St Vincent; uncommon on Guadeloupe.

Bibliography. Anon. (1998a), Bond (1956a, 1985), Chantler (1995b), Keith (1997), Raffaele *et al.* (1998), Ridgway (1911), Stattersfield *et al.* (1998), Stotz *et al.* (1996).

59. Grey-rumped Swift

Chaetura cinereiventris

French: Martinet à croupion gris **German:** Graubürzelsegler **Spanish:** Vencejo Ceniciento
Other common names: Sclater's Swift; Ashy-rumped Swift (*sclateri*)

Taxonomy. *Chaetura cinereiventris* P. L. Sclater, 1862, Bahía.

Sometimes considered conspecific with *C. egregia*, and these two form superspecies with *C. martinica*; these three previously placed in genus *Acanthylis* along with *C. spinicauda*. All races but nominate have been grouped together in what might be incipient species, *C. sclateri*. Seven subspecies recognized.

Subspecies and Distribution.

C. c. phaeopygos Hellmayr, 1906 - E Nicaragua to Panama.
C. c. occidentalis Berlepsch & Taczanowski, 1884 - W Colombia, W Ecuador and extreme NW Peru.
C. c. schistacea Todd, 1937 - E Colombia to W Venezuela.
C. c. lawrencei Ridgway, 1893 - N Venezuela and S Caribbean Is.
C. c. guianensis Hartert, 1892 - E Venezuela and W Guyana.
C. c. sclateri Pelzeln, 1868 - S Venezuela through S Colombia, NW Brazil (upper Amazonia) and E Peru to NW Bolivia.
C. c. cinereiventris P. L. Sclater, 1862 - E Brazil, Paraguay and NE Argentina (Misiones).

Descriptive notes. 10.5 cm; 19 g. Smallish swift with short square tail, rectrix spines up to 7 mm beyond web, protruding head and distinctive wing shape, with hooked outer wing and bulging midwing cutting in at body. Glossy black upperparts including tail, with broad grey rump and proximal uppertail-coverts; underparts light grey, darker only on undertail-coverts. Races *guianensis* and *lawrencei* similar, latter slightly darker below and typically with strong contrast between black undertail-coverts and mid-grey belly; *schistacea* as latter but underparts deep grey and upperparts darker with steely-blue gloss; *occidentalis* and *sclateri* dark forms, latter with greyer belly, with darkest rumps and blackish-grey underparts beneath upper breast; *phaeopygos* a dark form but undertail-coverts paler than in other races.

Habitat. Main habitats defined as tropical lowland evergreen forest, montane evergreen forest, flooded tropical evergreen forest and secondary forest. Occurs from sea-level to 1800 m, in Ecuador 200-1800 m, typically over slopes with forest or second growth; on Grenada over young secondary forest.

Food and Feeding. Flying ants, bees, wasps, beetles and flies taken. Feeds in lower strata of mixed flocks of swifts, which are often composed of congeners, as well as *Aeronautes* and *Streptoprocne*. Also associates with hirundines. Gregarious, usually seen in flocks of 20-40. Recorded hovering to catch insects from canopy.

Breeding. Collected in breeding condition in N Antioquia, Colombia, in Mar-Apr; breeds in SE Brazil from Sept/Oct to Feb/Mar and in Costa Rica Mar-Jul; thought to breed in Trinidad in rainy season. Nests in chimneys or similar structures with secluded vertical surfaces; nest half-cup, re-used and rebuilt at same site; birds observed carrying nesting material in bill; both adults incubate at night. Clutch 2-4.

Movements. Resident throughout much of range, though incompletely known. In Paraguay possibly a breeding species only, though recent studies indicate resident there and also in Misiones.

Status and Conservation. Not globally threatened. One of commonest *Chaetura* swifts throughout range, indeed abundant in some areas such as Río Negro Preserve, Colonia Libertad, Costa Rica. Occurs in several protected areas, e.g. Braulio Carrillo National Park (Costa Rica), Cueva del Guácharo National Park (Venezuela) and Iguazú National Park (Brazil/Argentina).

Bibliography. Anon. (1993a), Beebe (1949), Becker & López (1997), Belton (1984), Benstead *et al.* (1993), Best & Clarke (1991), Best *et al.* (1993), Bloch *et al.* (1991), Brooks, Barnes *et al.* (1993), Brooks, Clay *et al.* (1995), Canevari *et al.* (1991), Chantler (1995b), Chapman (1917), Cooper (1997), Giraudo *et al.* (1993), Graves & Zusi (1990b), Hayes (1995), Herklots (1961), Hilty & Brown (1986), Howell (1957), Krabbe & Somoza (1994), Madroño & Esquivel (1997), Marcus (1983), Marín (1993), Marín *et al.* (1992), Meyer de Schauensee & Phelps (1978), Parker & Remsen (1987), Parker *et al.* (1991), de la Peña (1994), Peres & Whittaker (1991), Raffaele *et al.* (1998), Ridgely & Gwynne (1989), Rogers (1939a), do Rosário (1996), Saibene *et al.* (1996), Scott & Brooke (1985), Sick (1948c, 1959, 1993, 1997), Slud (1964), Snow (1962a), Snyder (1966), Stiles & Skutch (1989), Stotz *et al.* (1996), Thomas (1990), Todd (1937b), Wetmore (1968a), Wunderle (1985), Zimmer (1953b).

60. Pale-rumped Swift

Chaetura egregia

French: Martinet de Bolivie **German:** Blaßbürtelsegler **Spanish:** Vencejo Egregio

Taxonomy. *Chaetura egregia* Todd, 1916, Río Surutú, Bolivia.

Sometimes considered conspecific with *C. cinereiventris*, and these two form superspecies with *C. martinica*; these three previously placed in genus *Acanthylis* along with *C. spinicauda*, and present species alternatively reported to be closely related to *C. spinicauda*. Monotypic.

Distribution. E Ecuador S through E Peru, W Brazil and NW Bolivia.

Descriptive notes. 10.5 cm; 23 g. Smallish swift with short square tail and rectrix spines extending beyond web, protruding head and distinctive wing shape, with hooked outer wing and bulging midwing, cutting in at body. Black upperparts with bronze gloss (blue in *C. cinereiventris*), whitish rump and proximal uppertail-coverts; pale throat on otherwise dark underparts; blackish undertail-coverts.

Habitat. Main habitat defined as tropical lowland evergreen forest. Occurs from lowlands to 1100 m. In Ecuador frequents lowlands and hills on E Andean slope, at altitude range of 200-1000 m; in N Peru recorded at 1050 m,

occurring over humid forest and more open landscapes.

Food and Feeding. Feeds mainly in lower strata of mixed flocks of swifts. Recorded with *C. cinereiventris*, *C. brachyura*, *Aeronautes montivagus*, *Cypseloides nylus* and *Panyptila cayennensis*.

Breeding. Not known. Three birds taken in Bolivia late Jun to early Jul were not in breeding condition.

Movements. Believed resident.

Status and Conservation. Not globally threatened. Presumed to be one of rarer *Chaetura* species and usually outnumbered by *C. cinereiventris* where they occur together. However, in San Martín and Amazonas, N Peru, commoner than *C. brachyura*, and considered to be abundant in upper elevations of Ecuadorian range. Present in Tambopata Reserve (Peru). Few museum specimens.

Bibliography. Brace *et al.* (1997), Chantler (1995b), Davis (1986), Marín (1993), Marín *et al.* (1992), Meyer de Schauensee (1982), O'Neill (1969), Parker & Remsen (1987), Remsen & Traylor (1989), Sick (1993, 1997), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Todd (1916).

61. Chimney Swift

Chaetura pelagica

French: Martinet ramoneur **German:** Schornsteinsegler **Spanish:** Vencejo de Chimenea

Taxonomy. *Hirundo Pelagica* Linnaeus, 1758, South Carolina.

Previously considered conspecific with *C. vauxi* and *C. chapmani*. Recent study suggests that this species may be related to *C. andrei meridionalis*. Monotypic.

Distribution. E North America, and occasionally California and Arizona. Winters in E Ecuador, W & E Peru, NW Brazil and N Chile, though precise range unclear.

Descriptive notes. 12-14 cm; 21 g. Medium-sized swift with short square tail, rectrix spines up to 7.5 mm beyond web, protruding head and distinctive wing shape, with hooked outer wing and bulging midwing cutting in at body. Underparts dark grey-brown beneath pale to mid-grey throat, which can be white in some. Most uniform *Chaetura* with little contrast between rump/uppertail-coverts and rest of dark grey-brown upperparts.

Habitat. Though readily associated with urban settings, also forages and breeds over variety of natural habitats over wide range. Main habitats defined as river-edge forest, edge of tropical low-

land evergreen forest and second-growth scrub. In SW Peru mainly along coast and in W Andean valleys, where regular to 2500 m and sometimes to 3000 m over irrigated farmland and both suburban and even central city zones. In Ecuador recorded at 300-1000 m on E slope, 2500 m in Valle de Quito,

and 3200 m in S Ecuador. Migration in Mexico from sea-level to 1500 m. In California mainly in coastal lowlands, though in Owen's Valley a summering population occurs at 1200 m.

Food and Feeding. Hymenoptera and Diptera recorded, among other insects. Food pellet may contain over 200 insects. Recorded taking a weevil (Curculionidae) which may have been flightless, probably from foliage of sweetgum tree in grove where flock of 40-50 swifts were feeding by fluttering near outer branches or diving through open upper storey. Occupies lower strata in mixed swift foraging groups. Highly gregarious. Seen in association with *Aeronautes undecolus* in WC Peru. May forage by hovering briefly at branches to take insects and spiders. Observed apparently trying to steal dragonfly (Odonata) from Purple Martin (*Progne subis*).

Breeding. Eggs recorded Illinois mid-May to early Jul, New York late May to early Jul, Virginia late May to mid-Jul, and Quebec mid-Jun to early Jul. Typically nests in chimneys, though other structures used; recorded nesting in abandoned Pileated Woodpecker (*Dryocopus pileatus*) nesting hole, though tree nesting now very rare. Half-cup of twigs with semicircular saliva support, 75-113 mm wide, 25-31 mm deep and 50-75 mm front to back; nests in buildings typically placed high above floor in darkness. Copulation at nest-site; may also occur in flight. Clutch 2-7, average 4.0-5.3; incubation begins with laying of penultimate egg, period 19-21 days; females tend to cover eggs or young at night during first week; initially, several nestlings fed by regurgitation at each visit, later food pellet given to just 1 nestling; young fed on average every 30 minutes in first week, every 45 in second and then more erratically; feeding intervals as low as 14-5 minutes recorded; nest vacated between days 14 and 19, with first flight typically on day 30. Extra-parental co-operation well established, 1 colony recording this in 38% of breeding pairs: 22 threesomes and 6 foursomes. Hatching success 90-5%; overall breeding success 86% with 3-6 young fledging per breeding effort; 46-5% of adults in 1 study returned to study area, while only 11% of nestlings produced returned.

Movements. Present North America Apr-Sept. Migrates through West Indies late Aug to late Oct and mid-Apr to mid-May, through Panama Oct-Nov and in spring throughout Apr, and through Mexico mid-Mar to mid-May and late Aug to early Nov. Present SW Peru Nov-Apr. Recorded mid-Feb to early Mar in coastal cordillera of W Ecuador; may represent spring migratory stopover. Rarely recorded SE Farallon Is, 42 km W of San Francisco, late May to mid-Jun and mid-Sept to early Oct. Vagrant Bermuda, rare but regular, late Mar to late Apr and early Aug to late Dec; Bahamas, late Apr to early May and Oct; Galapagos Is and Greenland. Transatlantic vagrant to Britain, 4 records, late Oct to early Nov, and Tenerife (Canary Is). Probably under-recorded in N South America.

Status and Conservation. Not globally threatened. Common and widespread throughout most of range. Rare and occasional breeder in W North American range, where known to breed only since 1975 after first observation in 1930. Statistically significant downward trends in 12 US states, only Louisiana recording a small but significant increase during 1966-1995. Both Canadian and US populations showed statistically significant annual decreases of -0.9% and -5.8% respectively.

Bibliography. Amadon (1936), Amos (1991), Araya *et al.* (1973), Arvin (1993), Baicich & Harrison (1997), Bartlett (1952), Barton (1958), Beissinger & Osborne (1982), Bent (1940), Bloch *et al.* (1991), Blodgett & Zammuto (1979), Bowman (1952), Brown (1980), Buden (1987b, 1993), Byrne & Graves (1992), Cammace & Fischl (1985), Carter (1967), Chantler (1993), Coffey (1936, 1937, 1938, 1942, 1943, 1956, 1958), Collins & Bull (1996), Cyr (1995b), DeGraaf & Rappole (1995), Demetrio (1993), Devillers (1970), Dexter (1950, 1951a, 1951b, 1951c, 1952a, 1952b, 1952c, 1956b, 1961b, 1969, 1974, 1979, 1981, 1987, 1990, 1992), Driessens (1994), Duke (1977), Dunn (1979), Edwards *et al.* (1992), Evans & Drickamer (1994), Ferguson & Ferguson (1991), Fischer (1951, 1958), Fjeldså & Krabbe (1986, 1990), Ganier (1944), George (1971), Hilty & Brown (1986), Hofslund (1958), Howell & Webb (1995a), Huey (1960), Hughes (1988), Jackson (1997), James (1950), Johnsgard (1979), Johnson (1972), Johnston (1958), Kaufman (1996), Lincoln (1944), Lowery (1943), MacNamara (1918), Marín (1993, 1997a), Meyer de Schauensee & Phelps (1978), Meyers & Odum (1991), Michael & Chao Wansih (1973), Miller (1978), Monroe (1968), Moore (1946), Olson (1993), Parmalee & Klippel (1982), Pickens (1935a), Plenge (1974), Pyle & Henderson (1991), Raffaele *et al.* (1998), Ramsey (1970), Ridgely & Gwynne (1989), Ridgely (1991), Rogers (1939a), Shelly (1929), Sick (1993, 1997), Skutch (1935), Slud (1964), Small (1994), Snow & Perrins (1998), Spendlow (1985), Stewart & Kantrud (1972), Stiles & Skutch (1989), Stotz *et al.* (1996), Sutton (1927), Walcott (1974), Walker (1944), Weber & Theberge (1977), Wetherbee (1961), Wetmore (1957b, 1968a), Wetmore & Swales (1931), Williams (1986), Zammuto (1978), Zammuto & Franks (1978, 1979a, 1979b, 1981a, 1981b), Zammuto *et al.* (1981), Zimmer (1945a, 1953b).

62. Vaux's Swift

Chaetura vauxi

French: Martinet de Vaux **German:** Graubauchsegler **Spanish:** Vencejo de Vaux
Other common names: Dusky-backed Swift; Richmond's Swift (*richmondii*); Yucatán Swift (*gaumeri*)

Taxonomy. *Cypselus* [sic] *Vauxi* J. K. Townsend, 1839, Fort Vancouver, Washington. Previously considered conspecific with *C. pelagica* and *C. chapmani*. Races *richmondii* (including *ochropygia*) and *gaumeri* previously considered distinct species. A recent study considers that race *aphanes* is synonymous with *C. andrei andrei*, latter taking priority, i.e. as *C. vauxi andrei*, or that there may be two races of *C. vauxi* in N Venezuela, *aphanes* in W coastal range and *andrei* in E coastal range and S & E lowlands; same study also suggests that *aphanes* is identical to *richmondii*; however, these views not universally accepted. Six subspecies recognized.

Subspecies and Distribution.

- C. v. vauxi* (J. K. Townsend, 1839) - W North America from British Columbia to S California; winters in Mexico and Guatemala.
- C. v. tamaulipensis* Sutton, 1941 - E Mexico.
- C. v. gaumeri* Lawrence, 1882 - Yucatán Peninsula and Cozumel I.
- C. v. richmondii* Ridgway, 1910 - S Mexico to Costa Rica and W Panama (Chiriquí).
- C. v. ochropygia* Aldrich, 1937 - E Panama.
- C. v. aphanes* Wetmore & Phelps, Jr., 1956 - N Venezuela.

Descriptive notes. 12 cm; 18 g. Medium-sized swift with short square tail, rectrix spines up to 8 mm beyond web, protruding head and distinctive wing shape, with hooked outer wing and bulging midwing cutting in at body. Olive-brown upperparts, with rump and uppertail-coverts more distinctly paler than in *C. pelagica*; underparts extensively whitish on throat, becoming darker distally, being dark only on undertail-coverts. Race *tamaulipensis* generally darker with green-glossed blackish upperparts and darker underparts; *richmondii* has darker upperparts and underparts, more extensive black bristles in front of eye and

stronger rectrix spines; *ochropygia* has blacker upperparts, though rump shows greater contrast;

gaumeri smaller than nominate and *C. pelagica* and slightly paler than *richmondii* with weaker rectrix spines; *aphanes* a dark race similar to *richmondii*, though some *aphanes* from W Venezuelan coastal range have paler breast and belly than those from E coastal range.

Habitat. Found over wide range of habitats, including cloudforest at 1000 m in N Venezuela, arid areas of Central America, and both temperate and arid areas of Pacific coast in lowlands and mountains. Main Neotropical habitats defined as tropical lowland evergreen forest, montane evergreen forest, tropical deciduous forest, secondary forest and second-growth forest. In Costa Rica typically at 700-2000 m, recorded to 3000 m and also into lowlands on both slopes; in Panama specimens have been collected at 1280-2070 m and in Mexico from sea-level to 3000 m. In N Venezuela, population of *aphanes* in wet W coastal range may have different ecological requirements from that in deciduous seasonal forest in E coastal range (and *C. andrei andrei* in S & E lowlands). Recorded nesting at 1150 m in Montana. In Californian coastal lowlands breeds mainly below 300 m; in Yosemite National Park breeds 1200-2130 m and recorded foraging to 3650 m. In California mainly in redwood forests in narrow coastal zone, with infrequent records from Sierra Nevada. In NE Oregon 85% of nest-sites were in old growth, all in cavities used for roosting by Pileated Woodpeckers (*Dryocopus pileatus*), while Californian ranges of these 2 species appear correlated. A study of 160 forested stands in 1991 revealed that this swift was present in 41% of old-growth stands and only 8% of logged ones, reflecting increased availability of suitable nesting trees in old growth.

Food and Feeding. Often forages in large numbers, also with hirundines and other swifts. Frequently associates with *Streptoprocne zonaris* in Sierra de Tuxtla, Mexico, in flocks of 10-200. Often forages in evening, and feeds up to 5-5 km from nest. In natural forest habitat favours open airways such as rivers and roads. In breeding season various species of Homoptera, Diptera, Ephemeroptera and Hymenoptera recorded.

Breeding. Mating displays seen and enlarged gonads in specimens taken in Mar-Apr in Panama; breeds Mar-Apr-Jul in Costa Rica, and May-Jul in Venezuela; eggs early May to early Jul, most records mid-late Jun, in California; laying mid-Jun to early Jul, broods late Jun to early Aug, in British Columbia; chicks in nest in early Jul, C Honduras; tree-nesting pairs in NE Oregon built nests during Jun, eggs hatching from late Jun to early Jul and young leaving nest in early-late Aug, 28-30 days after hatching. Solitary or colonial. Disused chimneys preferred in British Columbia, though other sites include hollow maples (*Acer*); traditional sites often predominate; uses cavities made by Pileated Woodpeckers in many areas. Natural nests observed in Montana in old "topped" western hemlocks (*Tsuga heterophylla*) with central cavities, while old-growth stands of Douglas fir (*Pseudotsuga menziesii*) favoured in Cascade Range, Washington; in latter state old-growth grand firs (*Abies grandis*) also used, 8 nests being found in area of 2 ha. Access achieved by flying vertically down; one chamber was 7-3 m down with nest 1-5 m from bottom. Nest is half-cup bracket of grass and twigs agglutinated with saliva and stuck to vertical wall, 100 mm wide, 40 mm deep and 60 mm front to back. Clutch 1-7; chimney nest with 7 eggs in Montana was incubated continuously for 19 days, by both parents equally; brooding was continuous initially; nestlings fed every 10-35 minutes, compared with average of 12 minutes in NE Oregon study; weight of young rapidly increased until day 18, whence remained relatively stable until young left nest and declined until first flights undertaken; young left nest after 20-21 days, remaining in chimney for further 7 days before first flights; adults and young had completely vacated nest 3 days after initial flight, but roosting individuals, mainly young from nearby nests, were recorded at night after that day. Average breeding success 67%, with 4 young fledging per breeding effort.

Movements. Nominate race a migrant, present in far N of range May to mid-Sept, exceptionally late Mar on coast. Migrates through S California mid-Apr to early May, with weaker autumn passage peaking early Sept, though continuing to early Oct, migrants leaving the state by mid-Oct. Recorded SE Farallon Is, 42 km W of San Francisco, in similar numbers over 22 years, in spring 813 in early-late May, and in autumn 803 early Sept to late Oct. Recorded E to Louisiana and Florida. Passage through NW Mexico Apr-May and mid-Sept to Oct; nominate race present C Mexico to W Honduras, mid-Sept to May. Incidence of wintering in California increasing, small flocks occurring mainly in S, though wintering as far as NW California not unknown.

Status and Conservation. Not globally threatened. Common throughout most of range, though often locally, e.g. in Montana during 1970's considered common in Idaho county while rare in adjacent Fortine. Survey work during 1966-1995 in North America indicates significant decrease in Californian population (-4.9% p.a.) but no statistically significant overall decline in either Canadian or US population. It has been suggested that lack of suitable nest-sites, primarily hollow snags in many areas, limits range expansion. Indeed, fate of many North American populations may depend on sensitive forestry policy, as it has been suggested that elimination of old growth from managed forests could lead to regional extinction. Neotropical abundance varies, e.g. common in parts of Costa Rica but uncommon in parts of N Belize.

Bibliography. Alcorn (1988), Baicich & Harrison (1997), Baldwin & Hunter (1963), Baldwin & Zackowski (1963), Bent (1940), Binford (1989), Bull (1991), Bull & Beckwith (1993), Bull & Blumton (1997), Bull & Collins (1993a, 1993b, 1993c, 1996), Bull & Cooper (1991), Bull & Hohmann (1993), Bull & Torgensen (1993), Campbell *et al.* (1990), Chantler (1993), Collins (1967c, 1971), Collins & Bull (1996), Cooper (1997), Davis (1937), DeGraaf & Rappole (1995), Dickinson (1951), Dunn (1979), Edson (1931), Finley & Finley (1924), Fischer (1958), Fix (1988), Gaffney (1986), Gómez de Silva (1998), Griffie (1961), Griscom (1932a), Howell, S.N.G. & Pyle (1993), Howell, S.N.G. & Webb (1995a), Howell, T.R. 63. Chapman's Swift

Chaetura chapmani

French: Martinet de Chapman **German:** Chapmansegler **Spanish:** Vencejo de Chapman
Other common names: Dark-breasted Swift

Taxonomy. *Chaetura chapmani* Hellmayr, 1907, Caparo, Trinidad.

Previously considered conspecific with *C. pelagica* and *C. vauxi*. Recent proposal to raise *viridipennis* to full species, but this is not universally accepted. Nominate race may consist of two disjunct populations, representing different races, one in lowlands from C Panama to N Colombia, the other from E Venezuela to NE Brazil, with intervening gap (W & N Venezuela) occupied by *C. vauxi*. Two subspecies recognized.

Subspecies and Distribution.

- C. c. chapmani* Hellmayr, 1907 - C Panama through Colombia, Venezuela and the Guianas to NE Brazil.
 - C. c. viridipennis* Cherrie, 1916 - E Peru, C & E Bolivia and W Brazil; winters to N Colombia.
- Descriptive notes.** 13-14 cm; 21.5-28 g. Medium-sized swift with short square tail, rectrix spines 6 mm beyond web, protruding head and distinctive wing shape, with hooked outer wing and bulg-

ing midwing cutting in at body. Glossy black upperparts with distinctly paler grey rump and uppertail-coverts; very uniform dark brown underparts. Race *viridipennis* larger. A recent study suggests that differences in gloss between subspecies result from age differences in specimens, and states that *viridipennis* differs from *C. andrei meridionalis* in culmen length and less contrasting and more uniform throat and rump coloration, and in having primaries P9 and P10 equal in length.

Habitat. Main habitats defined as tropical lowland evergreen forest, secondary forest and second-growth scrub. In Colombia occurs from

sea-level to 1600 m, in N Venezuela to 600 m and in S Venezuela to 200 m. Recorded throughout Trinidad, but prefers wooded terrain with hills and especially forested uplands. Also seen feeding close to sea-level over swamp and mangrove areas.

Food and Feeding. Forages in mixed flocks with *C. cinereiventris*, *C. spinicauda* and *C. brachyura*. Occurs in monospecific flocks in upper Rio Urucu, Amazonas, Brazil. Feeds close to ground in dense low cloud conditions.

Breeding. N nominate race breeds in wet season, late spring to early autumn; in Trinidad, nest in use early May to early Jun; *viridipennis* apparently breeds in austral summer. Known from 1 nest in Trinidad, 20 cm below top of cement manhole, in brushy savanna; half-cup nest 69 mm wide, 24 mm deep and 59 mm front to back. 2, possibly 3, eggs; incubation 17-18 days; young when less than 48 hours old flesh-pink, with traces of grey on bill and claws, lacking natal down, with whitish egg-tooth on tip of upper mandible, weight 1.5 g.

Movements. N nominate race resident within its range; *viridipennis* a transequatorial migrant, with Mar-Apr records from Antioquia, Colombia. Recorded late Aug. Los Fierros, Santa Cruz, E Bolivia.

Status and Conservation. Not globally threatened. One of rarer South American swifts with few specimens or observations over an apparently wide distribution; precise limits of breeding range not well known. However, recorded in 1960's with relative frequency in Val and Arima Valley, Trinidad. Commonly recorded in upper Rio Urucu, Amazonas, Brazil.

Bibliography. Bates *et al.* (1992), Cohn-Haft *et al.* (1997), Collins (1968a, 1968b), ffrrench & ffrrench (1966), Haverschmidt & Mees (1994), Herklots (1961), Hilty & Brown (1986), Kirwan & Sharpe (1999), Marin (1997a), Meyer de Schauensee & Phelps (1978), Peres & Whittaker (1991), Ridgely & Gwynne (1989), Rogers (1939a), Sick (1993, 1997), Snyder (1966), Stotz *et al.* (1996), Wetmore (1957b, 1968a).

64. Short-tailed Swift

Chaetura brachyura

French: Martinet polioüre **German:** Stutzschwanzsegler **Spanish:** Vencejo Rabón

Taxonomy. *Acanthylis brachyura* Jardine, 1846, Tobago.

Four subspecies recognized.

Subspecies and Distribution.

C. b. brachyura (Jardine, 1846) - Panama E to the Guianas and Trinidad, S to WC Brazil and N Bolivia.

C. b. praevelox Bangs & Penard, 1918 - Grenada, St Vincent and Tobago.

C. b. ocyptes Zimmer, 1953 - SW Ecuador and extreme NW Peru.

C. b. cinereocauda (Cassin, 1850) - NC Brazil.

Descriptive notes. 10 cm; 18 g. Smallish to medium-sized swift with protruding head, remarkably short square tail (wings appearing disproportionately long as a result), rectrix spines up to 5 mm beyond web, and distinctive wing shape, with hooked outer wing and deeply bulging midwing cutting in at body. Glossy purplish-black plumage, pale grey-brown distally from rump and vent. Race *praevelox* generally browner with slightly paler throat; *ocyptes* has longer tail and wings than other races and paler grey chin and throat, brown forehead and pale-fringed supercilary line; *cinereocauda* has even blacker throat than

nominate and generally green gloss.

Habitat. Main habitats defined as secondary forest, edge of tropical lowland evergreen forest, tropical deciduous forest and second-growth scrub. A lowland species recorded to 1900 m in Ecuador; recent studies showed presence at 200-1100 m on E Andean slope, though not usually seen above 800-900 m. Often seen on coast, especially over mangroves where it roosts, at least in Surinam; also over open areas, often arid but also llanos, and over primary or second-growth forest. In Villavicencio area of Colombia, restricted to remnant forest, morichales and second-growth where common. On Tobago over young secondary forest and scrub. Occasionally over human settlements.

Food and Feeding. Panamanian study showed that Diptera, Hymenoptera and Coleoptera predominated with lesser numbers (less than 5% of total diet) of Hemiptera (Heteroptera and Homoptera). Four specimens collected in Panama, during wet season, had been feeding on swarms of Hymenoptera. One stomach contained 384 fig wasps (Agaonidae) of 2 species and 160 ants of 3 species, among total catch of 702 prey items. Four spiders also recorded in 2 specimens from Panama. Food ball from Trinidad contained large number of spiders. Forages in lower strata of mixed swift flocks. Usually seen in small flocks, often with other *Chaetura* swifts. Pair studied in Trinidad believed to feed regularly 5 km from nest-site where feeding young. Takes insects and spiders from outer branches of trees by hovering briefly.

Breeding. In Trinidad breeds in summer rainy season, nesting rapidly after first rains early Apr to early Sept. Breeding initiated by May rains in Panama; male in breeding condition collected early Jun from Ayacucho, S Cesar, Colombia; colony of 8 pairs breeding in Bolivian chimney Sept-Nov. Started nesting in chimneys in 1930's. In main Trinidad study, 21 nest-sites were manholes and 1 a subterranean concrete walled room; in 4-month season made 1-3 breeding attempts, rarely 4, with interval of c. 4-74 days between ending previous attempt and starting new clutch. 2-7 eggs (average 3.8); incubation 17-18 days; hatching rates 51-5% of all eggs, 95% of those reaching expected hatching date; entire clutch hatched in 48-72 hours; initially long periods of brooding by day, becoming shorter but still 20-minute periods by day 8; nocturnal brooding, by 1 or both parents, until young too large to cover effectively, at c. 2 weeks; by day 2 both adults may be absent, probably foraging for young; most nestlings stayed in nest until 22-23 days after hatching and then clung to nest-cavity walls, where majority stayed until 30-36 days old; 53-5% of hatched young

successfully fledged. Average overall breeding success 27%, with 1-1 young fledging per breeding effort; predation by bats suspected.

Movements. Resident. Vagrant to St Croix, Puerto Rico.

Status and Conservation. Not globally threatened. Locally common throughout range, for example noted commonly over suitable habitat in Villavicencio area, Colombia, and in uplands of Reserva Ecológica de Loma Alta, Ecuador. Possible increase in some areas. Discovered in Panama as recently as 1960, where now known to be common in suitable habitat. Flock of c. 300 birds recently recorded in Choetó, NW Colombia, where species previously unknown.

Bibliography. Becker & López (1997), Beebe (1947, 1949), Best *et al.* (1993), Bloch *et al.* (1991), Bond (1956a), de Carvalho (1961), Collins (1967a), Davis (1986), ffrrench (1991), ffrrench & ffrrench (1966), Friedmann & Smith (1950), Haverschmidt (1958b), Haverschmidt & Mees (1994), Herklots (1961), Hilty & Brown (1986), Krabbe & Sornoza (1994), Marin (1993), McKay (1980), Meyer de Schauensee & Phelps (1978), Parker & Remsen (1987), Pearson (1975), Raffaele (1989), Raffaele *et al.* (1998), Ridgely & Gwynne (1989), Salaman & Gandy (1994), Sick (1993, 1997), Snow (1962a), Snow & Snow (1964), Snyder (1966), Stotz *et al.* (1996), Wetmore (1939, 1968a), Wunderle (1985), Zimmer (1953b).

65. Ashy-tailed Swift

Chaetura andrei

French: Martinet d'André **German:** Grauschwanzsegler **Spanish:** Vencejo de Tormenta
Other common names: André's/Southern Swift; Sick's Swift (*meridionalis*)

Taxonomy. *Chaetura andrei* Berlepsch and Hartert, 1902, Caicara, River Orinoco, Venezuela.

Recently suggested that nominate race be merged with *C. vauxi aphanes* (as *C. v. andrei*) and that *meridionalis* thus be given separate specific status. Several specimens formerly identified as *andrei* (e.g. from Carabobo, Falcón, Lara, Distrito Federal) are clearly *C. vauxi aphanes*, and of the 5 valid specimens of *andrei* 4 are from Bolívar (2 each from Caicara and Altigracia) and 1 from Sucre (San Félix); those birds mislabelled as *andrei* may either be post-breeding migrants of a *C. vauxi* population, perhaps from E part of Coastal Range, or may represent a resident form from hilly lowlands of S Venezuela; identification of 2 other specimens taken from near the Serranía de Imataca, S of Orinoco Delta, needs to be confirmed. Race *meridionalis* almost identical in plumage to *C. pelagica*, to which it may be closely related; best separated by differences in wing-formula, as P9 is 3-8 mm longer than P10 whereas in *C. pelagica* both are equal. Two subspecies recognized.

Subspecies and Distribution.

C. a. andrei Berlepsch & Hartert, 1902 - E Venezuela.

C. a. meridionalis Hellmayr, 1907 - E & SE Bolivia, SE & S Brazil, Paraguay and N Argentina; winters N to Panama, Colombia and French Guiana.

Descriptive notes. 13.5 cm; 21.5 g. Medium-sized swift with short square tail between *C. brachyura* and other *Chaetura* in length, and rectrix spines 2 mm beyond web; protruding head and distinctive wing shape, hooked in outer wing and with bulging midwing cutting in at body. Olive-brown upperparts with moderately contrasting paler grey rump/uppertail-coverts; diagnostic underpart markings, pale throat and relatively pale uppertail-coverts on otherwise dark brown underparts. Race *meridionalis* can have white throat; that race also much longer-winged and longer-tailed than nominate, wing mean 131.5 mm against

114.5 mm, tail mean 37 mm against 30-25 mm.

Habitat. Main habitats defined as edge of tropical lowland evergreen forest, secondary forest and second-growth scrub. Found from lowlands to 1600 m over wide range of habitats. Wintering *meridionalis* recorded over primary cloudforest from cordilleras of N Venezuela.

Food and Feeding. Typically in small foraging groups.

Breeding. Season end Aug-Jan S Brazil, Sept-Mar SE Brazil; nests Oct-Nov. Mato Grosso: lays late Nov, São Paulo state. Breeds commonly in chimneys and under eaves in urban areas and more naturally in hollow trees and buriti palms (*Mauritia*); site loyalty exhibited. Half-cup nest in buriti palm, of leaf stalks and often palm leaf fibres stuck with saliva to vertical wall; material may be collected from trees in flight, using feet; nest 85 mm wide, 37 mm deep and 43 mm front to back; re-used until it falls down, whereupon rebuilt on same spot. Clutch 3-4, less often 5; assumed that more than 1 female contributed to brood of 9 young in an attic nest, since other adults present at nest-site; both sexes undertake nesting duties; initially young fed intensely, with up to 61 feeds daily, declining as they mature. In São Paulo state, at least, timing of hatching seems to preclude possibility of second brood.

Movements. Race *meridionalis* at least partly migratory, crossing equator to reach Roraima from May; recorded in austral winter from Panama, N Colombia, Venezuela and Surinam, though scarcity there suggests some wintering occurs farther S, possibly among N breeding populations of this form. Arrives in breeding range early-mid Sept, earliest SE Brazil in late Aug. Irregular extended movements from breeding range up to mid-Apr. Non-breeding roost in Minas Gerais declines from Feb and species absent by mid-Apr. Difficult to ascertain post-breeding range, since at least part of breeding population in coastal Brazil may winter in that area or leave only briefly; few reliable winter records, with overlap of similar species. Breeding status in NE Brazil uncertain as birds may be at S limit of wintering range, N edge of breeding range, or just passing through. May overlap with *C. pelagica* in Bolivia and Argentina. Absent from Serra dos Orgãos (N of Rio) May to mid-Aug, from SE Brazil during coolest months, from Pocone (SW Mato Grosso) May-Nov, and largely from Paraguay during this season. Rarely recorded Bolivia, Feb and late Sept to early Oct. Colombian/Venezuelan llanos and Orinoco basin should be investigated as potential wintering grounds. Vagrant to S Rio Grande do Sul (Brazil) and Falkland Is.

Status and Conservation. Not globally threatened. Race *meridionalis* common within breeding range, though less often found within wintering range, and is most abundant Brazilian swift away from Amazon, though rare in Pocone; common in Paraguay. Occurs in Calilegua and El Rey National Parks (Argentina) and Itatiaia National Park and Nova Lombardia Biological Reserve (Brazil). Status of nominate race uncertain.

Bibliography. Abendroth (1953), de Andrade & de Freitas (1987), Belton (1984), Brooks *et al.* (1993), Canevari *et al.* (1991), Collins (1967c, 1968b), Contreras *et al.* (1990), Darlington (1931), Fjeldså & Mayer (1996), Haverschmidt & Mees (1994), Hayes (1995), Hilty & Brown (1986), Lowen, Barrina, Aiz & Tobias (1996), Marin (1997a), Maurício & Dias (1998), Meyer de Schauensee & Phelps (1978), Mitchell (1957), Norez *et al.* (1983), Oniki *et al.* (1992), de la Peña (1994), Phelps & Phelps (1958), Remsen & Traylor (1983), Remsen, Traylor & Parkes (1986), Ridgely & Gwynne (1989), Rogers (1939a), de Rosário (1996), Saibene *et al.* (1996), Short (1975), Sick (1948b, 1950b, 1959, 1993, 1997), Stotz *et al.* (1996), Wetmore (1926, 1968a).

PLATE 42

PLATE 42

Family APODIDAE (SWIFTS) SPECIES ACCOUNTS

Tribe APODINI

Genus *AERONAUTES* Hartert, 1892

66. White-throated Swift

Aeronautes saxatalis

French: Martinet à gorge blanche German: Weißbrustsegler Spanish: Vencejo Gorgiblanco

Taxonomy. *Acanthylis saxatalis* Woodhouse, 1853, Inscription Rock, New Mexico. Previously placed in *Apus*. Present species and *A. montivagus* apparently more closely related to each other than either is to *A. andecolus*. Two subspecies recognized.

Subspecies and Distribution.

A. s. saxatalis (Woodhouse, 1853) - SW Canada S through W USA to S Mexico (Oaxaca) W of Caribbean lowlands.

A. s. nigrior Dickey & van Rossem, 1928 - S Mexico (Chiapas) to C Honduras.

Descriptive notes. 15-18 cm; male mean 34 g, female mean 32 g. Medium-sized swift with sharply pointed outer wing, broad inner wing and large, shallowly forked tail. Black upperparts with distinctive white trailing edge to secondaries, white forehead and supercilium; broad white throat, extending in strip to central vent area; isolated white patches on rear flanks; underparts

otherwise black. Female averages narrower white trailing edge. Race *nigrior* has wholly darker head.

Habitat. A montane species found to 3000 m in Mexico and 2450 m in Guatemala, but sometimes descending to 600 m in Honduras. In California breeds from lowlands to 2130 m in Yosemite National Park, with foraging recorded to 4270 m. Occurs around canyons and cliff-faces, both coastal and interior, and arid areas, though meadows important for foraging and species never breeds far from these. Importance of water indicated by 8-year study in Anza-Borrego Desert, California, where

despite mainly drought conditions creeks continued to flow and this species occurred in suitable canyons. Seen foraging over pinyon, yucca and creosote plant zones in Joshua Tree National Monument, California. Summer resident in Apache County, Arizona, occurring over grassland and around rocky cliffs; over a range of habitats on migration. Occurs as non-breeding insectivore in Chihuahuan desert, Mexico. Main Neotropical habitats defined as arid montane scrub, pine-oak forest and second-growth forest.

Food and Feeding. 21 stomachs contained Diptera, mainly Anthomyiidae, with fewer Dolichopodidae, Sarcophagidae and Bibionidae, Coleoptera, especially Aphodidae, Hymenoptera, and true bugs, mainly Pentatomidae, Membracidae, Cicadellidae and Coreidae. In 2 stomachs over 90% of prey insects were ants, and another stomach contained entirely march flies (Bibionidae). Recorded feeding on insects disturbed by combine harvester. Often highly gregarious.

Breeding. Laying early May to late Jun, peaking late May to early Jun, California; clutches recorded mid-May to early Jul and broods early Jun to mid-Aug, British Columbia. Colonial. May copulate in flight. Nests in suitable rock niches, on cliffs, including sea cliffs, beneath overhangs, and also in buildings where suitable holes present; will breed in disused hirundine nests; great site loyalty with continuous use over many decades. Cupped nest of grasses, moss and with some feathers, either self-supporting on vertical wall or placed on ledge; nest agglutinated with saliva which also secures it in place. Clutch 3-6 eggs.

Movements. Nominate race partial migrant. Present British Columbia in far N of range, early Apr to late Sept, most departing from late Aug. Migrant Californian population present mid-Mar to mid-Oct. Winters S California and Nevada where absent from coldest areas; it has been suggested that predominance of coastal winter records in Baja California suggests at least limited seasonal altitudinal movements. Most winter farther S, some as far as Honduras. Migrates in flocks, up to 50. Rarely recorded SE Farallon Is, 42 km W of San Francisco, during Apr and mid-late Oct. Race *nigrior* resident. Data from Belize unconfirmed.

Status and Conservation. Not globally threatened. Common throughout much of North American range, but rare in Mexico and uncommon in Honduras. Considered uncommon to fairly common in recent census of mountainous areas of S California and common in parts of Arizona. Recent survey work revealed slight yet significant decline (by 2.0% per annum) in USA during 1966-1995.

Bibliography. Alcorn (1988), Alden & Mills (1976), Austin & Rea (1976), Baieich & Harrison (1997), Baltosser (1986b), Bartholomew *et al.* (1957), Behle (1973, 1976), Bent (1940), Binford (1989), Campbell *et al.* (1990), Cardiff & Remsen (1981b), Collins (1973), Collins & Johnson (1982), Dawson (1923), DeGraaf & Rappole (1995), Dickey & van Rossem (1928), Dobkin *et al.* (1986), Enderson & Craig (1974), Fretwell (1978), Howell & Webb (1995a), Johansson & White (1995), Johnsgard (1979), Kaufman (1996), Lentz (1993), Lima (1993), Linsdale (1938), Massey (1994), McCrary *et al.* (1986), McNicholl (1975), Michael (1926), Monroe (1968), Oberholser (1920), Peterson (1990), Pickwell (1937), Preston (1986), Pyle & Henderson (1991), Raitt & Pimm (1976), Ridgway (1911), Rogers (1939b), Rohwer (1971), Root (1988), Rosenberg & Terrill (1986), Seyfert (1984), Small (1994), Stotz *et al.* (1996), Summers (1995a), Unitt *et al.* (1995), Weber (1975), Weydemeyer (1975).

67. White-tipped Swift

Aeronautes montivagus

French: Martinet montagnard **German:** Bergsegler **Spanish:** Vencejo Montañés
Other common names: Mountain Swift

Taxonomy. *Cypselus montivagus* d'Orbigny and Lafresnaye, 1837, Santa Cruz de la Sierra, Bolivia. Previously placed in *Apus*. Present species and *A. saxatilis* apparently more closely related to each other than either is to *A. andecolus*. Race *tatei* originally placed in monotypic genus *Duidia*. Two subspecies recognized.

Subspecies and Distribution.

A. m. montivagus (d'Orbigny & Lafresnaye, 1837) - Scattered range from N Venezuelan cordilleras S through Andes to NC Bolivia and NW Argentina.

A. m. tatei (Chapman, 1929) - *tepulis* of S Venezuela and extreme N Brazil.

Descriptive notes. 13 cm; 20 g. Smallish swift with broad inner wing, sharply pointed outer wing and large, shallowly forked tail; black-brown upperparts with narrow white trailing edge to secondaries and white tips to tail; underparts and much of face black with broad white throat-patch and white patches on vent and rear flank. Female lacks white tail-tips. Race *tatei* has glossed blue-black upperparts.

Habitat. Main habitats defined as montane evergreen forest, secondary forest and tropical lowland evergreen forest. A montane species of subtropical zones occurring over forest, both primary and second growth, and open slopes

at 500-2700 m in Andes, 1500-2700 m on W slopes of inter-Andean Zone, Ecuador, and 700-1900 m in *tepulis*; recorded to 3200 m in WC Andes. Not infrequently over human settlements, especially derelict buildings such as at Rancho Grande, N Venezuela, where large breeding colony; also, especially in poor weather, in valley bottoms including arid ones. In NW Argentina occurs over deep canyons, maintaining altitude in erratic wide circles before moving to another area to repeat operation; also noted with *Chaetura andrei* at 1700 m, Abra de Cañas.

Food and Feeding. Forages in lower strata in single-species or mixed swift flocks. Typically in flocks of up to 20.

Breeding. Breeds Apr-Jul, N Venezuela; seen entering possible nest-sites early Apr. Colombia; breeding in Valle de Guayllabamba, Ecuador, apparently not synchronized, evidence from collected birds suggesting some start breeding in Nov-Dec. Colonial. Nests in rock fissures in ravines and in holes in buildings, but no information on nest morphology, eggs or young.

Movements. Resident.

Status and Conservation. Not globally threatened. Locally common, indeed locally abundant, at least in Ecuador. Perhaps more widespread than hitherto believed, since recently recorded from new sites in Venezuela, and noted on several occasions since 1993 fin Calilegua National Park, NW Argentina.

Bibliography. Beebe (1949), Best *et al.* (1993), Boesman (1998), Chapman (1929, 1931), Davis (1986), Dickerman & Phelps (1982), Fjeldsá & Krabbe (1990), Fjeldsá & Mayer (1996), Friedmann (1948), Gilliard (1941), Hilty & Brown (1986), Kirwan (1996c), Marín (1993), Marín *et al.* (1992), Mazar, Clark *et al.* (1998), Meyer de Schauensee & Phelps (1978), Moschione (1993), Remsen & Traylor (1989), Salaman & Gandy (1994), Sick (1993, 1997), Stotz *et al.* (1996), Willard *et al.* (1991), Zimmer (1953b).

68. Andean Swift

Aeronautes andecolus

French: Martinet des Andes **German:** Andensegler **Spanish:** Vencejo Andino

Taxonomy. *Cypselus andecolus* d'Orbigny and Lafresnaye, 1837, La Paz, Bolivia. Previously placed in *Apus*, even when *A. saxatilis* and *A. montivagus* were separated in *Aeronautes*. Proposed race *dinellii* from Jujuy (NW Argentina) now incorporated into nominate race. Three subspecies currently recognized.

Subspecies and Distribution.

A. a. parvulus (Berlepsch & Stolzmann, 1892) - W Andes of Peru to extreme N Chile.

A. a. peruvianus (Chapman, 1919) - E Andes of Peru.

A. a. andecolus (d'Orbigny & Lafresnaye, 1837) - C Bolivia to W Argentina (Río Negro).

Descriptive notes. 14 cm. Medium-sized swift with broad inner wing, sharply pointed outer wing and long, deeply forked tail; black upperparts broken by narrow white trailing edge to secondaries, white rump band and white collar; largely white/off-white below on face, throat and underparts, with buff-mottled flanks and ventral area. Race *parvulus* slightly smaller than nominate and very contrastingly plumaged; *peruvianus* smaller than nominate with shorter and more shallowly forked tail; lacks buff tints to white plumage and has darker undertail-coverts and more interrupted collar.

Habitat. Main habitats defined as arid montane scrub and semi-humid or humid montane scrub. Typically over semi-arid mountainous areas, often bushy or with scattered cacti and more rarely over forested slopes, at 340-3900 m (2500-3550 m in Peru and Bolivia, 2000-2500 m in southernmost areas of range). Has been recorded above 4100 m in Peru.

Food and Feeding. Gregarious and highly mobile forager; associates with wintering *C. pelagica*. **Breeding.** Observed entering hole in road cutting where young were being fed, early Dec, N Tarapacá, Chile. Recorded nesting in holes in steep rock-faces, but nest form not recorded.

Movements. Resident. May move as a result of snowstorms at high altitude.

Status and Conservation. Not globally threatened. Common throughout range, except N Chile where uncommon and irregular at Arica, Camarones Gorge and Chusmisa in mountains of Tarapacá. Local and irregular in parts of Argentina.

Bibliography. Araya & Chester (1993), Bond & Meyer de Schauensee (1943), Canevari *et al.* (1991), Chapman (1919), Fjeldsá (1991), Fjeldsá & Krabbe (1990), González & Málaga (1997), Hughes (1988), Johnson (1967), Koepeke (1970), Krabbe *et al.* (1996), Narosky & Yzurieta (1993), Neller (1993), Nore *et al.* (1983), de la Peña (1982, 1994), Plenge (1974), Remsen & Traylor (1989), Remsen, Traylor & Parkes (1986), Stotz *et al.* (1996), Vuilleumier (1969), Wetmore (1926), Zimmer (1953b).

Genus TACHORNIS Gosse, 1847

69. Antillean Palm-swift

Tachornis phoenicobia

French: Martinet petit-rolé **German:** Kubasegler **Spanish:** Vencejillo Antillano
Other common names: Palm Swift(?)

Taxonomy. *Tachornis phenicobia* Gosse, 1847, Jamaica.

Formerly placed alone in present genus. Two subspecies recognized.

Subspecies and Distribution.

T. p. iradii (Lembeye, 1850) - Cuba and I of Pines.

T. p. phoenicobia Gosse, 1847 - Jamaica; Hispaniola and nearby islands of Saona, Beata and Vache.

Descriptive notes. 9-10 cm. Small swift with large, obviously forked tail; black-brown upperparts broken by large white rump band with dark central stripe; white throat and central belly patch on otherwise brown underparts. Race *iradii* larger with deeper tail-fork, sootier upperparts and paler flanks and face.

Habitat. Main habitats defined as low, seasonally wet grassland and second-growth scrub. Mainly a lowland species, though can be recorded in mountains; collected at 450 m at Bombardopolis, Haiti. Always closely associated with royal palms (*Roystonea*), often close to human habitation, even in large cities. In

Port-au-Prince, Haiti, occurs around gardens with palms.

Food and Feeding. Encountered in small groups, occasionally with hirundines and other swifts. Observed entering a tannery to feed on flies inside low, open sheds.

Breeding. Seen entering clusters of dead palm fronds in May; believed to be feeding young in early Apr. Breeds colonially in palms. Nest is a globular construction of soft materials agglutinated with saliva, with nest cup at base. Clutch 3-5. No other information.

Movements. Resident, with vagrancy to Florida Keys and Puerto Rico suggesting some dispersal. **Status and Conservation.** Not globally threatened. Locally common in suitable habitat on all islands within its range. Occupation of man-made habitats such as large cities, e.g. Santo Domingo, suggests species is relatively adaptable and therefore secure.

Bibliography. Anon. (1998a), Barbour (1943), Bond (1956a, 1985), Dod (1987), Downer & Sutton (1990), Gundlach (1873), Kepler (1971), Lembeye (1850), Raffaele *et al.* (1998), Ridgway (1911), Stotz *et al.* (1996), Wetmore & Lincoln (1933), Wetmore & Swales (1931).

70. Pygmy Swift

Tachornis furcata

French: Martinet pygmée **German:** Däumlingssegler **Spanish:** Vencejillo Venezolano

Taxonomy. *Micropanyptila furcata* Sutton, 1928, Guachi, Zulia, Venezuela.

Previously placed in monospecific genus *Micropanyptila*; alternatively, on occasion in *Reinarda*, with *T. squamata*. Two subspecies recognized.

Subspecies and Distribution.

T. f. furcata (Sutton, 1928) - NE Colombia and NW Venezuela.

T. f. nigrodorsalis (Aveledo & Pons, 1952) - W Venezuela.

Descriptive notes. 10 cm. Tiny swift with long thin wings and long, deeply forked tail; uniformly brown upperparts; whitish throat, separated from whitish mid-belly by brown breast band with rest of underparts mid-brown. Race *nigrodorsalis* has blacker upperparts and whiter throat.

Habitat. Main habitats defined as tropical lowland evergreen forest, secondary forest and second-growth scrub. Habitats include primary and secondary forest, cultivated land and open areas with scattered trees, though must contain palms on which species depends for nest-sites.

Food and Feeding. Forages in small, highly active flocks.

Breeding. Pair collected at nest-site in late Jul, Catatumbo lowlands, Colombia. Noted to have similar nest structure to better-studied *T. phenicobia*, with similar dependency on palms.

Movements. Believed resident.

Status and Conservation. Not globally threatened. Restricted-range species: present in Caribbean Colombia and Venezuela EBA. Tiny range and small numbers of sites for which species is known suggest that population studies are urgently required.

Bibliography. Aveledo & Pons (1952), Bond (1956b), Hilty & Brown (1986), Meyer de Schauensee (1982), Meyer de Schauensee & Phelps (1978), Olrog (1968), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Sutton (1928).

71. Fork-tailed Palm-swift

Tachornis squamata

French: Martinet claudia **German:** Gabelschwanzsegler **Spanish:** Vencejillo Tijereta

Other common names: Neotropical Palm-swift, Fork-tailed Swift

Taxonomy. *Cypselus squamatus* Cassin, 1853, Guyana.

Previously placed in genus *Reinarda*, alone or with *T. furcata*. Two subspecies recognized.

Subspecies and Distribution.

T. s. semota (Riley, 1933) - E Ecuador and NE Peru through E Colombia and NW Brazil to S & E Venezuela; possibly also N Bolivia.

T. s. squamata (Cassin, 1853) - the Guianas and Trinidad to C & E Brazil.

Descriptive notes. 13 cm; 12 g. Smallish swift with very long, deeply forked tail and long thin wings; black-brown upperparts; large white throat separated from white mid-belly by thin brown breast band; underparts otherwise brown. Race *semota* generally much darker with less feather fringing than nominate.

Habitat. Main habitats defined as palm forest, river-edge forest, low, seasonally wet grassland and second-growth scrub. Recorded from Amapá, N Brazil, over Amazonian upland savanna. Depends on buriti (*Mauritia*) palms for nest-sites, whether in an urban setting (often in good numbers in city parks), open landscapes

such as *llanos*, or forest clearings. Habitat survey in Villavieciencia area, Colombia, showed reliance on morichales biome, species being absent from all 8 other habitat types. Also around *Bactris* palms in Ecuador. Occurs to 1000 m but typically much lower, 200-1000 m on E slope of Ecuadorian Andes.

Food and Feeding. Not particularly gregarious, occurring in flocks of up to 10, and just as likely to be seen with Blue-and-white Swallow (*Notiochelidon cyanoleuca*) as with other swift species. Feeds at very low levels or just over canopy, and in lower strata of mixed swift flocks.

Breeding. In Trinidad breeds Apr-Jun; in Colombia fledgling collected late Feb near Leticia and male in breeding condition collected Vaupés, May; in Mato Grosso, Brazil, breeding behaviour recorded late Sept to Nov. Solitary. Requires buriti palm (*Mauritia*) leaves, which, on withering, crack at base to hang down at trunk; nest a J-shaped pouch 13 cm long, inner walls mainly down-lined, outer copiously feathered and rather disorderly, adhered with saliva at top and curving away from leaf, leaving entrance 30 mm across at base to egg trough, latter sited in middle of leaf some 16 cm from crack; nest wall 5 mm, 20 mm below egg trough; outer wall of trough 60-70 mm, inner wall 35 mm, depth 15 mm. 3 eggs, possibly secured to egg-shelf using saliva; incubation period 21 days.

Movements. Resident. May migrate in parts of Brazil, as absent from Borba (Rio Madeira), Mar-Nov. **Status and Conservation.** Not globally threatened. Locally common throughout range within morichales habitat. Common at Limoncocha, E Ecuador, and across Venezuelan and Colombian *llanos*. Relatively abundant in some urban areas, such as towns and cities of N Venezuela.

Bibliography. Duhs (1992), ffrench (1991), Friedmann (1948), Friedmann & Smith (1950), Gilliard (1941), Haverschmidt & Mees (1994), Herklots (1961), Hilty & Brown (1986), Marín (1993), Marín *et al.* (1992), McKay (1980), Meyer de Schauensee & Phelps (1978), Paz y Miño (1989), Pearson (1975), Remsen & Traylor (1989), Riley (1933), Schubart *et al.* (1965), Sick (1948a, 1993, 1997), da Silva *et al.* (1997), Snyder (1966), Stotz *et al.* (1996), Thomas (1990), Willis & Oniki (1993), Zimmer (1953b).

Genus *PANYPTILA* Cabanis, 1847

72. Great Swallow-tailed Swift

Panyptila sanctihieronymi

French: Martinet de San Geronimo **Spanish:** Vencejo Tijereta Grande

German: Großer Schwalbensegler

Other common names: Geronimo Swift

Taxonomy. *Panyptila sancti-hieronymi* Salvin, 1863, San Gerónimo, Vera Paz, Guatemala. Monotypic.

Distribution. S Mexico (Nayarit and Jalisco S to Chiapas), C Guatemala and S Honduras.

Descriptive notes. 18-20 cm; 50 g. Large swift with long thin wings and long, very deeply forked tail; black upperhead, white collar contiguous with large white throat, and black upperparts with white trailing edge to remiges; underparts black apart from white throat and rear flank patches.

Habitat. Main habitats defined as montane evergreen forest, pine forest, secondary forest and arid montane scrub. Mainly over montane habitats, 1200-1500 m in Mexico, 600-2000 m in Guatemala, and usually above 1000 m in Honduras, but recorded from lowlands of La Selva, Costa Rica, and to 500 m in valleys of

Honduras, when sometimes over human settlements. Typically over wild and rocky terrain.

Food and Feeding. 2 stomachs contained large numbers of winged termites and single pentatomid bugs (*Solubea pugnax*). One of least gregarious apodids. Often seen foraging at high elevation and at great speed.

Breeding. Very large tube-like nest, 660 x 150 mm, adhered along length, consisting of felt-like plant material agglutinated with saliva, with feathers attached to outside. As well as basal entrance, false entrance sited on tube side.

Movements. Generally considered resident, though series of Costa Rican and Nicaraguan records in Sept-Nov and Mar-Apr and movements in lowlands of NW Mexico close to sea-level during Dec-Jan suggest some degree of dispersal.

Status and Conservation. Not globally threatened. Uncommon to fairly common in Mexico and Guatemala; considered common in Honduras. Only recorded from Mexico for first time as recently as 1944, and there are still relatively few published records.

Bibliography. Álvarez del Toro (1952), Anon. (1998a), Binford (1989), Carr & Dickinson (1951), Griscom (1932a), Hernández-Baños *et al.* (1995), Howell & Webb (1994, 1995a), Land (1970), Monroe (1968), Ridgway (1911), Rowley (1984), Salvin (1863), Schaldach (1963), Selander (1955), Sick (1958), Stiles & Skutch (1989), Stotz *et al.* (1996).

73. Lesser Swallow-tailed Swift

Panyptila cayennensis

French: Martinet de Cayenne

German: Kleiner Schwalbensegler

Spanish: Vencejo Tijereta Chico

Other common names: Cayenne Swift

Taxonomy. *Hirundo cayennensis* J. F. Gmelin, 1789, Cayenne.

Separation into races may prove to be unjustified. Two subspecies currently recognized.

Subspecies and Distribution.

P. c. veraecrucis R. T. Moore, 1947 - E Mexico (Veracruz) to N Honduras.

P. c. cayennensis (J. F. Gmelin, 1789) - S Honduras S through Central America, with scattered distribution in W Colombia, Ecuador, Peru, NE Bolivia, Brazil, Venezuela, Trinidad and the Guianas.

Descriptive notes. 13 cm; 18 g. Medium-sized swift, black with white collar, throat and rear flank patches. Structure and plumage remarkably similar to much larger *P. sanctihieronymi*, but more grey-brown in collar area than latter; also shorter-winged (average nominate 119 mm and *veraecrucis* 126-8 mm, *P. sanctihieronymi* 188 mm). Race *veraecrucis* larger than nominate.

Habitat. Main habitats defined as tropical lowland evergreen forest and secondary forest. Mostly lowlands and foothills, to 1000 m in Mexico, 1500 m in Guatemala, 300 m in Honduras, 800 and 1000 m in Costa Rica on

Caribbean and Pacific slopes respectively, 1400 m in Colombia, 1000 m in Venezuela, and 1500 m in Ecuador where mainly below 900 m, with broader altitudinal range on Andean W slope (300-1500 m) than on E (200-600 m). Occurs over a variety of habitats, rarer in more arid areas, clearings and edges of primary or secondary forest, cultivated areas, over human habitations and rivers.

Food and Feeding. Occurs in mixed groups with *Chaetura* and *Cypseloides*, but generally less gregarious than other apodids, not typically in flocks of over 6. Feeds in lower strata of mixed flocks with *Cypseloides* or *Streptoprocne*, but in their absence occupies higher levels than other swifts.

Breeding. Recorded Costa Rica Jan-Jun, Panama Mar-Aug, and Caldas, Colombia, Apr and Dec. In Brazil occupied nests found in Mato Grosso in Feb and in Pará Jun-Sept, and nestlings in Rio de Janeiro in Nov. Solitary. Recorded nesting under eaves, against walls of occupied houses, inside deserted buildings and large forest trees. Two nest types: either sock-shaped, fixed by sole to branch, with entrance a narrow sleeve hanging from sole, or long sleeve attached for whole length to trunk or wall; both consist of plant down with felt-like structure, feathers frequently adhered to outside, agglutinated with saliva; dimensions range from 240 x 90 mm and 355 x 75 mm to 480 x 165 mm; entrance typically 10-50 mm wide. Clutch 2-3. Both adults roost in nest throughout year.

Movements. Resident. Recorded as rare vagrant during Nov over secondary-scrub habitat 30 km S of Caracas, Venezuela, in 18 years, suggesting only small degree of dispersal.

Status and Conservation. Not globally threatened. Local and uncommon, to locally fairly common in optimum habitat, such as Hill Bank, N Belize. Fairly common to uncommon in Central American range; perhaps less abundant in South America, where rare to uncommon in Ecuador, and uncommon in Venezuela and Colombia. Usually encountered in small numbers only.

Bibliography. Arnold (1966), Beebe (1949), Boesman (1998), Carr & Dickinson (1951), Edwards (1959), Graves & Zusi (1990b), Greenway (1934), Haverschmidt (1954a, 1971), Haverschmidt & Mees (1994), Herklots (1961), Hilty (1977), Hilty & Brown (1986), Howell & Webb (1995a), Kiff (1975), Kirwan & Sharpe (1999), Marín (1993), Marín *et al.* (1992), Meyer de Schauensee & Phelps (1978), Monroe (1968), Moore (1947b), Munves (1975), Pacheco & Whitney (1995), Parker & Remsen (1987), Parker *et al.* (1991), Peres & Whittaker (1991), Ridgely & Gwynne (1989), Ridgway (1911), Rogers (1939a), Salaman & Gandy (1994), Schulenberg & Parker (1981), Sick (1947, 1958, 1993, 1997), Slud (1964), Snyder (1966), Stiles & Skutch (1989), Stotz *et al.* (1996), Teixeira *et al.* (1988), Thomas (1993), Valley & Whitman (1997), Weimore (1968a), Zimmer (1953b).

Genus *CYPSIURUS* Lesson, 1843

74. African Palm-swift

Cypsiurus parvus

French: Martinet des palmes **German:** Palmensegler **Spanish:** Vencejo Palmero Africano
Other common names: Palm Swift (when joined with *C. balasiensis*); Madagascar Palm-swift (*gracilis*)

Taxonomy. *Cypselus parvus* Lichtenstein, 1823, Nubia.

Forms superspecies with *C. balasiensis*, with which previously considered conspecific. Race *gracilis* (with *griveaudi*) may prove to be a distinct species. Eight subspecies currently recognized.

Subspecies and Distribution.

- C. p. parvus* (Lichtenstein, 1823) - Senegambia to Ethiopia, S to S Sudan; also SW Arabia.
- C. p. brachypterus* (Reichenow, 1903) - Sierra Leone to NE Zaire, S to Angola; islands in Gulf of Guinea.
- C. p. myochrous* (Reichenow, 1886) - S Sudan to NE South Africa (Transvaal), preferring highlands.
- C. p. laemostigma* (Reichenow, 1905) - coastal lowlands from S Somalia to Mozambique.
- C. p. hyphaenes* Brooke, 1972 - N Namibia and N Botswana.
- C. p. celer* Clancey, 1983 - Mozambique to Natal.
- C. p. griveaudi* Benson, 1960 - Comoro Is.
- C. p. gracilis* (Sharpe, 1871) - Madagascar.

Descriptive notes. 16 cm; 10-18 g. Very small swift with very long, very deeply forked tail, usually appearing needle-thin when tightly closed, and long, very thin wings. Pale grey-brown upperparts, with head and particularly wings appearing darker; underparts uniform and very pale with some streaking on throat; underwing-coverts darker than underbody. Male has whiter throat than female. Juvenile has more rufous fringes than fresh adult and lacks long emarginate outer rectrices. Race *laemostigma* darker, throat more mottled, and smaller; *myochrous* as latter with more greenish gloss; *brachypterus* darker than preceding races, throat

as nominate; *hyphaenes* paler than nominate, with least marked throat; *celer* similar to *myochrous*, though warmer tone with restricted pale fringing and fine streaking restricted to upper throat; *griveaudi* very dark with heavy streaking on throat and upper breast; *gracilis* darker than African races, with heavily streaked throat, juvenile with deeper tail-fork than juveniles of other races.

Habitat. Always contains palms, particularly fan palms, on which depends largely for nest-sites, though sympathetically constructed bridges also now used to some extent. Suitable palm species found from arid to rainforest zones. In Saudi Arabia occupies areas of Tihamah coastal plains where doum palm (*Hyphaene thebaica*) present. In Liberia, where infrequent within forest blocks, uses coconut (*Cocos*) and more locally *Borassus*, but not oil palm (*Elaeis*). Similarly choosy in S Africa, where pinnate palms generally shunned, whereas large dense population thrives in *Hyphaene* palm belt in N Botswana and Owambo. Typically occurs in lowlands, to 1100 m in Madagascar and rarely to 1700 m on Comoros; mainly below 1400 m in Kenya, though breeding locally to 1800 m. On Comoros prefers lowlands, where occurs through coconut belt without reaching forest edge areas.

Food and Feeding. Recorded contents from 32 stomachs: flies 17, ants 6, termites 4, beetles 3, c. 100 winged termites 1, and many small ants 1. Noted in groups of 4-8 at Kariba, Zimbabwe, with Lesser Striped Swallows (*Hirundo abyssinica*), Wire-tailed Swallows (*H. smithii*) and *Neafraus boehmi* in lowest of 3 feeding levels, below 20 m. This stratification apparent only when several species present; fed at other levels when alone or with just 1 other species. Believed to be most crepuscular swift in South Africa, where feeding period overlaps that of microchiropteran bats.

Breeding. Over much of range breeds year-round, though mainly in warmer months. Laying dates: May-Aug, Senegambia; Sept-Oct and Jun, Liberia; May, Burkina Faso; Nov-Jun, N Nigeria; Sept-Oct, Principe I; Apr-May, Jul-Aug and Nov-Jan, Cameroon; Mar, Central African Republic; Nov-Sept, Sudan; Jan and perhaps Jun, Ethiopia; Mar, May-Oct and Dec-Jan, majority Aug-Sept, Zambia; Mar, Jun-Jul, Sept-Oct and Dec-Jan, Malawi; year-round, of 288 nests 9% Apr-Jun, 37% Dec-Jan, Zimbabwe; Jun-Nov, South Africa; Sept-Nov, Madagascar; eggs and juvenile recorded late Sept, Comoro Is. Solitary or colonial. Typically nests in palms but man-made structures also used, as are leaves of *Dracaena*; recorded nesting in *Eucalyptus*, where nest placed in leaf clusters, in area lacking indigenous palms. Nest consists primarily of seed-down, more when cotton floss used, and typically soft feathers, agglutinated with saliva and sited on upper side of palm frond, or next to trunk between base of 2 fronds on *Washingtonia* palms; nest cup protrudes 4-15 mm away from back wall of nest and 45-120 mm along frond, and is 45-55 mm wide. Copulates only at nest. Typically 2 eggs, though 1 and 3 recorded, and 3 on average in Madagascar, with first egg laid 10 days after nest-building started; both sexes incubate, at night with partner resting on nest pad or close by, with frequent change-overs; rigid incubation posture with abdomen pressed against eggs, eyes remaining open during day; great variation in incubation percentage time noted, not clearly correlated with climatic variables; similar extremes noted in brooding, also by both sexes; incubation not always apparent in rain; average incubation period in Tanzania 20 days; at hatching, adult presses young tightly to nest; within hours of hatching young very restless, even while being brooded; from day 4 vertical crawling away from flange; little brooding from day 9; only 1 young fed on each visit, mean feeding rates per chick per 200 minutes 3.8 for brood of 1, 2.75 for brood of 2; average fledging period 31 and 33 days for broods of 1 and 2, respectively. In Tanzania, of 35 eggs laid, 23 hatched and 6 young fledged; average breeding success 17%, with 0.3-1.9 young fledged per breeding attempt.

Movements. Resident over much of range, but present only during summer in most southerly breeding area in South Africa. Extralimital records probably indicate range expansion. Two unidentified *Cypsiurus* at Al Ain in 1996 were first United Arab Emirates record.

Status and Conservation. Not globally threatened. Common to locally abundant. In Kenya commonest on coastal strip and far less apparent in W. Locally common in Tihamah coastal plains of Saudi Arabia. Race *gracilis* very common in Madagascar and *griveaudi* common on Comoros. Scarcest in areas of recent colonization. Use of exotic *Washingtonia* palm, native to SW USA, considered a major cause in recent range expansion, which is continuing in S Africa and seems to have begun in 1930's. However, westward expansion of African elephant (*Loxodonta africana*) into Okavango, coupled with frequent fires, may threaten species locally as a result of palm reduction.

75. Asian Palm-swift

Cypsiurus balasiensis

French: Martinet batassia **German:** Bengalsegler **Spanish:** Vencejo Palmero Asiático

Taxonomy. *Cypselus Balasiensis* J. E. Gray, 1829, India.

Forms superspecies with *C. parvus*, with which previously considered conspecific. Sulawesi in process of being colonized from S, by either *infumatus* or *bartelsorum*. Species name often erroneously listed as *batasiensis*. Four subspecies recognized.

Subspecies and Distribution.

- C. b. balasiensis* (J. E. Gray, 1829) - Indian Subcontinent W of Assam hills.
- C. b. infumatus* (P. L. Slater, 1865) - Assam hills to Indochina, Malay Peninsula, Sumatra and Borneo.
- C. b. bartelsorum* Brooke, 1972 - Java and Bali.
- C. b. pallidior* McGregor, 1905 - N & E Philippines.

Birds that have recently colonized S & SE Sulawesi may be either *infumatus* or *bartelsorum*.

Descriptive notes. 13 cm. Very small swift with long thin wings and long, deeply forked tail shorter than that of adult *C. parvus* and lacking streamer-like emarginated outermost rectrices. Mid-grey upperparts, slightly paler rump; pale grey underparts, underwing-coverts appearing darker, with unstreaked throat. Race *infumatus* darker, especially on rump and glossy black-brown rectrices and outer remiges, with shorter tail and shallower tail-fork; *bartelsorum* lacks fringing in juvenile and has lightly streaked throat; *pallidior* paler than *infumatus*, rump quite uniform with mantle, tail shorter and less forked than in *bartelsorum*.

Habitat. Primary dependence on fan palms (*Livistona*, *Borassus*, *Corypha*, *Arecia*) but in some areas thatched roofs used as nesting and roosting sites. Forages adjacent to sites, especially over mangroves and paddy, where palms prevalent. Although mainly a lowland species, as are fan palms, recorded to 1000 m in India and Sri Lanka, 1500 m in Java and Myanmar, and 1320 m on Sulawesi. Common even in city parks. Rarest in dense forest, though clearings and edges utilized. Resident over scrub and dry deciduous forest in Mudumalai Wildlife Sanctuary, SW India.

Food and Feeding. Hemiptera, Coleoptera and Hymenoptera recorded. Detailed Malaysian study of nestling diet (both faeces and bolus) found Coleoptera, Isoptera, Hymenoptera, Diptera, Homoptera and Ephemeroptera, with predominance of flying ants, termites and beetles. Mean open-country foraging height 13.3 m. Frequent in mixed flocks with other swifts and hirundines. Forages particularly actively in evening. Very gregarious; recorded in flocks of up to 1000, though 40 or below more frequent. In S India large numbers feeding on alate rice earhead bugs (*Leptocoris acuta*) were most active in early morning, numbers decreasing from 10:00 onwards as temperature increased.

Breeding. Virtually year-round with local variation of peak, mainly Mar-Aug in lowlands and Apr-Jun in hills, India; Dec to early Jul, Malay Peninsula; recorded Oct and Apr, Sumatra, but probably also year-round. Solitary. Typically nests on palm fronds, but where these are scarce will nest in eaves of thatched roofs. Nest is flimsy half-cup of seed-down (Malaysian study revealed sole use of either *Ceiba pentandra* or *Phragmites communis*) agglutinated with saliva, c. 10 mm deep x 40-50 mm wide, supporting apron extending over 50 mm above nest; feathers also used, under 5% in Malaysian study, to lesser extent than in *C. parvus*; eggs not glued to nest with saliva as in *C. parvus*, perhaps due to deeper, more secure, egg chamber and more continuous incubating habits during stormy weather; sited under palm leaves or near midrib frond of older leaves which hang down almost vertically; nest in Malaysia completed in 8 days. Clutch 2 eggs, though 1 and 3 recorded, mean 1.93 in Malaysia; both sexes incubate for c. 78% of time, though incubation continuous during inclement weather; mean feeding interval 45 minutes, shortest early morning and longest midday; adults incubate in vertical position, mean period for last egg 18 days; in 2-egg clutches 1-day interval between eggs hatching; young initially blind and naked, primary feathers in pin on day 6 and split on day 14, eyes opening on day 7 and movement in nest vicinity on day 14; young cling to apron when nest becomes too full; mean nestling period 28.5 days. Overall egg success 38%. Two clutches recorded in 46% of nests, with interval between first brood fledging and start of second clutch 8-26 days.

Movements. Resident.

Status and Conservation. Not globally threatened. Common to locally abundant. Least common where fan palms at lowest density. May be absent where palm crowns vigorously cut back, perhaps due to loss of roosting sites. Apparent range expansion in parts of Wallacea: first recorded in 1978 in S & SE Sulawesi, where now quite common; single record from Talaud Is of 3 birds in Sept 1995, presumably referring to birds of race *pallidior*; report of many birds at Kapan, Timor, in Jan 1990 would, if confirmed, imply a major range extension.

Bibliography. Abdulali (1984), Abdulali & Hussain (1972b), Ali (1996), Ali & Ripley (1983), Andrew & Holmes (1990), Baker (1934a), Bangs & Van Tyne (1931), Brooke (1972b), Chakravarthy & Purna Chandra Tejasvi (1992), Chantler (1993), Cheng Tsohsin (1987), Coates & Bishop (1997), Daniels (1997), Danielsen *et al.* (1994), Deignan (1945), Dharmakumarsinhji (1947), Dickinson *et al.* (1991), Duckworth & Kelsh (1988), Escott & Holmes (1980), Etchépaca & Hue (1978), Evans, Dutton & Brooks (1993), Evans, Magsalay *et al.* (1993), Gimmegg *et al.* (1998), Hachisuka (1934), Hails & Turner (1984), Hellebrekers & Hoogerwerf (1967), Hornskov (1996), Inskipp, C. & Inskipp (1991), Inskipp, T. *et al.* (1996), Lee *et al.* (1996), Lekagul & Round (1991), MacKinnon & Philipps (1993), Madoe (1976), Majumdar *et al.* (1992), van Marle & Voous (1988), Medway (1975a), Medway & Wells (1976), Meyer de Schauensee & Ripley (1940), Parrot & Andrew (1996), Philipps (1996), Philipps & Riley, J. PLATE 43

inches 6
cm 15

Genus *TACHYMARPTIS* Roberts, 1922

76. Alpine Swift

Tachymarptis melba

French: Martinet à ventre blanc **German:** Alpensegler **Spanish:** Vencejo Real
Other common names: Ceylon White-bellied Swift (*bakeri*)

Taxonomy. *Hirundo Melba* Linnaeus, 1758, Gibraltar.

Genus *Tachymarptis* has commonly been merged into *Apus*, but nowadays increasingly separated; differs in feather lice, foot structure of nestling, large size and tendency towards white underparts. Race of Mali birds not yet established, but their isolation from other breeding populations suggests it could be an undescribed race. Proposed race *striatus* from Mt Kenya is synonym of *africanus*. Subspecies name *dorabatai* often misspelt *dorabatai*. Ten subspecies currently recognized.

Subspecies and Distribution.

T. m. melba (Linnaeus, 1758) - S Europe through Asia Minor to NW Iran; winters in W & E Africa.
T. m. tuneti (Tschusi, 1904) - C & E Morocco through Middle East and Iran (except NW) to SE Kazakhstan and W Pakistan; winters in W & E Africa.
T. m. archeri (Hartert, 1928) - Somalia, SW Arabia N to Dead Sea depression.
T. m. maximus (Ogilvie-Grant, 1907) - Mt Ruwenzori (Uganda/Zaire).
T. m. africanus (Temminck, 1815) - E & S Africa and SW Angola; S birds winter in E Africa.
T. m. marjoriae (Bradfield, 1935) - Namibia to NW Cape (South Africa).
T. m. willsi (Hartert, 1896) - Madagascar.
T. m. nubifuga (Koelz, 1954) - Himalayas; winters in C India.
T. m. dorabatai (Abdulali, 1965) - W peninsular India.
T. m. bakeri (Hartert, 1928) - Sri Lanka.
Also resident (subspecies unknown) in Mali.

Descriptive notes. 20-22 cm; 104 g. Very large swift with broad wings and shallowly forked tail relatively shorter than in *Apus*; olive-brown upperparts lacking prominent saddle, outer wing appearing blacker; underparts with white throat and highly distinctive large oval white patch encircled by olive-brown breast band, flanks and undertail-coverts. Races *tuneti* and *marjoriae* paler, with grey-brown plumage; *archeri* averages paler than *tuneti*, with shorter wings; *maximus* largest race, with very dark, blackish plumage; *africanus* and *nubifuga* smaller than nominate, with blacker plumage, smaller throat patch and blacker shaft-streaks

on white areas; *willsi* and *bakeri* both smaller, with darker plumage and broader and narrower breast bands respectively; *dorabatai* has broader breast band and shorter wings than *nubifuga* and separated from *bakeri* by its lighter plumage and broader breast band.

Habitat. A polytypic species occurring over a wide range of habitats and foraging over vast areas. In W Palearctic in temperate and Mediterranean zones, typically in mountains but occasionally in lowlands. In remainder of sub-Saharan Africa and S Asia occurs from sub-desert steppe to equatorial mountains. Typically breeds below 1500 m, sometimes to 2200-2300 m. May breed above 4000 m on high mountains in Kenya and forage to 3700 m in Himalayas. Seen entering probable nesting sites at 2100 m on Madagascar.

Food and Feeding. Swiss food balls for nestlings averaged 219 prey items, ranging from 11 to 626, mean weight 2.53 g, mainly Hymenoptera, Coleoptera and spiders. Seventeen food balls comprised 308 flies, 200 beetles, 125 aphids, 94 wasps, 21 spiders, 16 cicadas (Cicadidae), 15 lacewings (Neuroptera), 2 ants and 2 butterflies. Other Swiss prey species were wood wasps (*Sirex gigas*), drone honeybees (*Apis mellifera*) and dragonflies. In Africa grasshoppers and winged termites also taken. A single bug species comprised the vast majority of prey in a series of stomachs from Zaire. In South Africa believed to be a significant predator in spring around commercial apiaries during cool, windy, overcast weather. Usually forages higher than most other swifts, e.g. in highest feeding level, 30-40 m, at Kariba, Zimbabwe, but will feed at low levels, especially during inclement weather. Has been observed taking cicadas flushed by a human. Will feed at night either where lights attract insects or even in total darkness as recorded in Saudi Arabia.

Breeding. Season Mar-Jun, Israel: laying Morocco Apr-May, Samarkand from early May, C Europe mid-late May or in bad weather as late as early Jun, Zimbabwe Aug, South Africa Sept-Jan; nestlings being fed Caucasus early Jul, Kugitang Mts (Central Asia) mid-Jul; fledging from nest Dagestan, Caucasus, early Jul; breeding behaviour noted late Sept and mid-Oct, Madagascar. Colonial, mixed colonies with *Apus barbatus* frequent; colonies may last for hundreds of years. Monogamous, with bond of at least 11 years recorded. Uses ledges or holes in cliff-faces or tall man-made structures; nest-site used in successive years by pair. Nest saucer-shaped, consists of downy feathers from many species, and swift primaries, tightly bound with dried plant matter and saliva. 125 x 130 mm, mean height 39 mm on level surface and 49 mm on angled surface in Europe, typically with central depression averaging 28 mm on horizontal surfaces; nest bowls on flatter surfaces average deeper; in Africa those attached to vertical rock-face externally 90 x 110 mm, inner bowl 100 x 110 x 20 mm, those wedged in vertical crack 80 mm wide measured 70 mm deep, internal bowl 80 x 110 x 20 mm. Copulation by nest or in air. Typically 3 eggs (1-4); incubation 17-23 days with nest duties shared by both sexes; whole clutch hatches within 24 hours; average 10 feeds daily; nestling period 53-66 days. In Switzerland, 94% of eggs hatch successfully and 78-98% of broods fledge; overall breeding success 70%, with average of 1.8-2.4 young fledged per breeding effort. Breeds first at 2-3 years, less frequently at 1 year.

Movements. Nominate race, *tuneti*, *nubifuga* and S African populations of *africanus* migratory. Migrants at high altitude, and often movements observed only when poor weather forces birds down. Palearctic breeding populations leave Sept to mid-Oct, returning from mid-Feb, later farther N, e.g. late Mar to early Apr to Switzerland. Main migration through Belen Pass, S Turkey, Oct-Nov, where in smaller flocks than *Apus apus* and mainly in single-species groups. At Bosphorus migratory picture unclear, as large Istanbul population embarks on early-morning feeding movements, but peak autumn

passage early Sept. In Israel, autumn passage late May to mid-Dec, peaking Sept-Oct; spring passage mid-Jan to mid-Jun, peaking mid-Feb to late Mar; huge migration noted over West Bank in mid-Mar 1987, when 10,000 flew N in 15 minutes, only 50-100 m above ground. In Natal performs altitudinal migration from 1500-2400 m to below 900 m. Recorded once along Egyptian Nile in Feb, in Arab Gulf states on 3 occasions Nov-Jan; small numbers, mostly *tuneti*, winter Israel, mainly in desert areas; S African populations partially migratory: breeding areas occupied Aug-May, with migration noted May-Jun and Aug-Oct through Zimbabwe, Mar-Apr and Aug-Oct Malawi, and probably Apr and Sept Botswana. Other races in Africa and India show some non-breeding dispersal, thought to be linked to monsoon. Large numbers recorded Feb-Apr in N Liberia of unknown migratory provenance, since Palearctic and African migrants believed to occur in that country and breeding cannot be ruled out. Annual overshooting migrant to British Is and C & N Europe; 3 Caribbean records.

Status and Conservation. Not globally threatened. Locally fairly common to common throughout much of range. Locally abundant in some areas, e.g. Turkey, Central Asian republics and parts of Africa where resident; perhaps increasing in S Africa, where increasingly using buildings as nest-sites. One colony lost in late 1960's as a result of dam construction. Locally abundant also in Indian Subcontinent. Swiss population has fluctuated, with minimum of 1250 pairs annually during 1970-1974, at least 61% utilizing buildings; severe weather in 1974 caused crash to maximum of 320 pairs during 1975-1978, subsequently increased to 1200-1300 pairs in 1994. Similar fluctuations reported from Bulgaria (decline of large colony from 300-500 pairs to c. 100 pairs) and Italy (desertion of colonies due to poor spring weather). Range expansion, with some regional increases, within stable European population. Swiss population has increased since 1990 as purpose-built nestboxes have been sited on many tall buildings. Population estimates in 1997: Europe 44,614-62,482 breeding pairs, Turkey 10,000-200,000 pairs.

77. Mottled Swift

Tachymarptis aequatorialis

French: Martinet marbré **German:** Schuppensegler **Spanish:** Vencejo Ecuatorial

Taxonomy. *Cypselus aequatorialis* von Müller, 1851, Ethiopia.

Genus *Tachymarptis* has commonly been merged into *Apus*, but nowadays increasingly separated; differs in feather lice, foot structure of nestling, large size and tendency towards white underparts. It has been suggested that resemblance to *Apus bradfieldi* may be more than superficial, hinting at closer alliance between these forms, which were formerly considered conspecific. Races proposed for birds from W slope Mt Ruwenzori (*schubotzi*) and NW Cameroon (*bamendae*) not distinct from nominate race and included within it. Includes "*Apus reichenowi*". Four subspecies currently recognized.

Subspecies and Distribution.

T. a. lowei (Bannerman, 1920) - Sierra Leone to Nigeria.
T. a. furensis (Lynes, 1920) - Darfur (W Sudan).
T. a. aequatorialis (von Müller, 1851) - Eritrea and Ethiopia S to Mozambique and E Zimbabwe; also SW Angola and NW Cameroon (*Bamenda*).
T. a. gelidus (Brooke, 1967) - SW Zimbabwe.

Descriptive notes. 23 cm; male 92.5 g, female 96 g. Very large swift with long, broad wings and long, moderately forked tail; blackish mantle contrasts slightly with head and distinctly with rump; inner wing paler than blackish outer wing; blackish underparts heavily barred, with indistinct pale throat patch. Race *gelidus* similar but smaller, with whiter throat, greyer upperparts and blacker barring on breast; *furensis* may average larger than nominate, with greyer upperparts, more extensive throat patch and pale belly patch caused by narrow barring in that area; *lowei* intermediate between nominate and *furensis* below, with upperparts similar to *gelidus*.

Habitat. Breeding restricted to granite highlands, where recorded up to 3000 m, occasionally higher, although widely scattered range encompasses both arid and equatorial mountain ranges. Forages widely and encountered over adjoining habitats, often at great height. Where sympatric with *T. melba*, generally breeds at lower elevations.

Food and Feeding. Recorded prey comprises ants, including *Crematogaster* (*Acrocnolia*), ichneumonid flies (Ichneumonidae) with other Hymenoptera, flies, termites and frequently beetles. In low-level foraging, feeds mainly on honeybees (*Apis mellifera*). Gregarious, typically in flocks of 20-40 and often with other swift species, especially *T. melba*, but occasionally in very large flocks of up to 1000.

Breeding. Laying dates: Ghana Jun and Oct, Nigeria possibly Nov-Jun, Ethiopia Jul, Kenya Feb-Mar, probably with 2 breeding seasons at Njorowa Gorge coinciding with rainy seasons, Tanzania Jun-Jul and Nov, Malawi Aug-Sept, Zambia Oct, Zimbabwe Jun and Aug-Nov; *furensis* have enlarged gonads Jun and small gonads Feb-Mar; specimen of *lowei* taken in breeding condition late

On following pages: 78. Alexander's Swift (*Apus alexandri*); 79. Common Swift (*Apus apus*); 80. Plain Swift (*Apus unicolor*); 81. Nyanza Swift (*Apus niansae*); 82. Pallid Swift (*Apus pallidus*); 83. African Swift (*Apus barbatus*); 84. Forbes-Watson's Swift (*Apus berliozi*); 85. Bradfield's Swift (*Apus bradfieldi*); 86. Pacific Swift (*Apus pacificus*); 87. Dark-rumped Swift (*Apus acuticauda*); 88. Little Swift (*Apus affinis*); 89. House Swift (*Apus nipalensis*); 90. Horus Swift (*Apus horus*); 91. White-rumped Swift (*Apus caffer*); 92. Bates's Swift (*Apus batesi*).

Apr. Typically colonial; males allegedly outnumber females by 50% and, though monogamous, this may indicate co-operative breeding; colonies poorly synchronized. Nest built over several weeks in vertical, or close to vertical, crack in rock-face, under rock overhang or 2-3 m above cave floor in vertical cleft; at least 6 m clear airspace needed for approach unless in cave; dry granite rock favoured. Sturdy, bracket-shaped nest consists of wind-dispersed seeds and feathers with leaves agglutinated with saliva, adhered to vertical surface or on 45° overhang, measuring 80-87 mm wide, 60-65 mm front to back and 25-48 mm deep. Clutch 1-2; both sexes incubate.

Movements. Poorly understood. Non-breeding dispersal implied by wide scatter of records away from breeding areas and by common occurrence of non-breeding (presumed) nominate race during summer in W Sudan and as far W as Chad. Will follow storms, where presumably benefits from updraughts. Rare visitor to W Liberia on 4 occasions, late Feb to early Apr. Vagrant to Hexrivier Pass, Cape Town, some 1000 km from limit of breeding range.

Status and Conservation. Not globally threatened. Common to abundant in much of range. Very localized within W African range, though large numbers recorded from Wase Rock, Nigeria, e.g. 2500 roosting in Mar 1997. Numerical status of Angolan or Cameroon populations unknown.

Bibliography. Anon. (1997a), Balança & de Visscher (1993, 1997), Bannerman (1933, 1953), Bednall (1958, 1959, 1963), Benson (1952), Benson & Benson (1977), Benson *et al.* (1971), Brooke (1967, 1968, 1969a, 1969c, 1971b, 1971, 1973a), Cave & Macdonald (1955), Cheke & Walsh (1996), Cooke (1965), Devise (1992), Dowsett (1976, 1989a), Dowsett & Dowsett-Lemaire (1978a), Duckworth *et al.* (1992), Elgoud *et al.* (1994), Field (1998), Fry *et al.* (1988), Gatter (1997), Ginn *et al.* (1989), Grimes (1974, 1987), Harrison *et al.* (1997), Karcher (1989), Lippens & Wille (1976), Louette (1981), Lynes (1925), Maclean (1993), Masterson (1945, 1946), Nikolaus (1987), Osborne (1975), Osborne & Osborne (1978), Pinto (1983), Short *et al.* (1990), Snow (1978), Steyn (1966b), Zimmerman, D.A. *et al.* (1996).

Genus *APUS* Scopoli, 1777

78. Alexander's Swift

Apus alexandri

French: Martinet du Cap-Vert **German:** Alexandersegler **Spanish:** Vencejo de Cabo Verde
Other common names: Cape Verde Swift

Taxonomy. *Apus unicolor alexandri* Hartert, 1901, São Nicolau, Cape Verde Islands. Affinities unclear. Formerly considered conspecific with *A. unicolor*; recently suggested to be more closely related to *A. pallidus*, *A. barbatus* or *A. niansae*, although these proposals appear to be based mainly on speculation. Only known eggs, described in 1898, were considered unique amongst Apodiformes in being speckled reddish brown; a second clutch reported in 1986, however, consisted of pure white eggs, as in other Apodiformes, suggesting that the first set were probably misidentified; implications drawn from the first eggs have greatly confused the issue of relationships. Monotypic.

Distribution. Cape Verde Is. where occurs throughout (except Santa Luzia), including small islet of Raso, but thought to breed only on Santiago, Fogo, Brava, Santo Antão and São Nicolau.

Descriptive notes. 13 cm. Small, short-winged swift with relatively shallow tail-fork and distinctive fluttering flight; darkest black-brown on outer wing, wing-coverts, tail and mantle, with paler brown forehead and rump, the latter producing a prominent saddle; underparts paler still with broad, diffuse, off-white throat-patch; rest of underparts darker away from throat, pale brown lightly barred darker.

Habitat. Occurs over all habitats on small island range, foraging from sea-level up to peaks of highest mountains, e.g. 2830 m on Fogo. Breeds up to 1600 m.

Food and Feeding. Forages alone or in parties of up to 30.

Breeding. Noted visiting nest-sites Aug-Sept; eggs collected early Apr and mid-Nov; breeding suspected Jan-Mar, early Jun and Aug-Sept on Santiago, Feb on São Nicolau and Aug-Sept on Brava. Nests in cliff fissures and in houses. 2 eggs, plain white.

Movements. Resident, though foraging birds, or non-breeders, occur on E islands and São Vicente. Occasional absence noted from some islands, e.g. São Vicente and Santo Antão in Jan-Feb 1966.

Status and Conservation. Not globally threatened. Restricted-range species; present in Cape Verde Islands EBA. Common, with largest numbers on Fogo and Brava. Population not accurately censused, but certainly numbers in the thousands. Early records indicate abundance on São Nicolau.

Bibliography. Alexander (1898), Bannerman (1953), Bannerman & Bannerman (1966, 1968), Beaman & Madge (1998), Boume (1955, 1957), Brooke (1971b, 1971i), Chantler (1993), Cramp (1985), Dowsett & Dowsett-Lemaire (1993), Driessens (1994), Hazevoet (1995), Hazevoet *et al.* (1996), Lack (1956a), de Nairois (1986, 1994a), Noeske & Plütze (1994), Norrevang & Hartog (1984), Snow & Perrins (1998), Stattersfield *et al.* (1998), White (1960).

79. Common Swift

Apus apus

French: Martinet noir **German:** Mauerssegler **Spanish:** Vencejo Común
Other common names: (Eurasian/European/Northern) Swift

Taxonomy. *Hirundo Apus* Linnaeus, 1758, Sweden.

Forms superspecies with *A. unicolor* and *A. niansae*; has been considered conspecific with both, and also with *A. barbatus*. Birds breeding in SW Asia have been separated in race *marwitzi*, but not widely accepted. Israeli population somewhat intermediate between nominate race and *pekinensis*. Two subspecies normally recognized.

Subspecies and Distribution.

A. a. apus (Linnaeus, 1758) - W Palearctic E to L Baikal, SE towards Iran; winters mainly from Zaire and Tanzania S to Zimbabwe and Mozambique.

A. a. pekinensis (Swinhoe, 1870) - Iran E through W Himalayas to Mongolia and N China; winters primarily in Namibia and Botswana.

Descriptive notes. 16-17 cm; 36-52 g. Large rakish swift with long, deeply forked tail and sharply pointed wings; black-brown mantle, outer wing, lesser coverts, tail, crown and underparts beneath

small off-white throat patch; slightly paler inner wing, greater coverts of underwing, forehead and rump; contrast between paler and darker tracts varies individually and temporally, fresh feathers being blacker with narrow white fringes. Juvenile very black, with little contrast between tracts; white fringes most apparent on forehead, which can show as small white patch, and larger, more defined white throat-patch. Race *pekinensis* has paler forehead and shows greater contrast in wing.

Habitat. Wide range of habitats from arid steppe and desert on S & E boundaries, temperate and Mediterranean zones N into boreal zone; also

over all sub-Saharan habitats. Recorded from sea-level to high altitude. Abundance in Britain and Ireland seemingly correlates with climate; commonest in relatively warm and dry S & E, becoming scarcer to N & W, where cooler, wetter and windier weather reduces insect abundance. In Israel primarily in Mediterranean climatic zone, with only small numbers in semi-desert areas. Race *pekinensis* occurs in Himalayas at 1500-3300 m, foraging to 4000 m, and recorded migrating at 5700 m in Ladakh. **Food and Feeding.** Prey up to 12 mm taken, with stinging insects avoided. Over 500 prey species noted in European diet. German study analysed 11,384 insects and 17 spiders: 53% were Hemiptera, 26% Coleoptera, 10% Diptera and 3% Lepidoptera and Neuroptera.

Breeding. Season: Mar-Jun, Israel; probably May-Jun, Pakistan and Kashmir; mid-May to late Jul Britain and Ireland, and a week earlier and later in Switzerland and Fennoscandia respectively; in Turkmenistan, nest-building at Kopet-Dag in Apr, completed nest Kyzylcha-kala in early May, clutches completed in Ashkhabad from late Apr; laying NW Africa in May, and Russia early-mid Jun. Colonial, though solitary nests not infrequent; separate nests, typically over 1 m apart. Site prospected and chosen by male; initially female greeted with hostile display, though allopreening occurs when she submits by lifting head to expose throat patch; copulation on wing and at nest. Nests mainly in buildings, but in remote parts of range also in tree hollows and rock crevices. Nest cup constructed of small pieces of vegetable matter and feathers, agglutinated with saliva, measuring 125 × 110 mm, internal diameter 45 mm. Clutch 1-4, averaging 2 in N Africa but typically more in Europe; both sexes share nesting duties equally; incubation, initiated by laying of last egg, occurs in equal periods of c. 2 hours, more intensive when weather poor; period 19-5 days; brooding continuous in first week, discontinuous from second, with young unattended during inclement weather; down that grows from day 13 is extensive by day 17, being fully replaced by day 30; feeding rate depends on weather, average 10 food balls daily in Gibraltar; 2 young share food ball until large enough to swallow one whole by day 14; nestlings restless from 2-3 weeks, with wing exercises and allopreening; average fledging period 42.5 days (wide range of 37-56 days due to weather conditions), self-initiated fledging after sunset or prior to 08:00. Average breeding success 58-65%, with mean 1.3-1.7 young fledging per breeding effort.

Movements. Long-distance migrant. Present at SW Palearctic sites from mid-Mar, arriving later farther N; main arrival N Europe early May, with migration persisting to early Jun. Main spring and autumn passage in Egypt late Mar to mid-May and mid-Aug to mid-Oct; records in late Jan to early Feb could indicate local wintering or early migration. Spring migration of nominate race through Israel mid-Jan to mid-Jun, peaking Apr-May; passage S throughout country mid-May to mid-Nov; in spring *pekinensis* moves mainly in Mar-Apr, occurring primarily in E in autumn. Leaves N Europe from late Jul, mainly Aug, very rare from Nov. Autumn movement over W Turkish migration watchpoints peaks mid-late Aug. Present on African wintering grounds from Sept. Broad-front autumn migration from Europe on SSW bearing, returning by generally more E route. Race *pekinensis* departs South Africa by early Mar, nominate race leaving somewhat earlier, late Jan to early Feb. Winters in small numbers N of Sahara, e.g. Cape Verde Is, with records Aug-Jun, possibly in Egypt among flocks of *A. pallidus* along Nile, in Israel and Arab Gulf states. Vagrant to many oceanic archipelagos, including Pribilof Is off Alaska (1 record, Jun) and Prince Edward Is in S Indian Ocean.

Status and Conservation. Not globally threatened. Declines apparent in some areas of Europe at least, where breeding population recently reported to have decreased in 12 countries. In Britain and Ireland, census work during 1968-1972 revealed an estimated 100,000 pairs; between then and 1989-1990 there is no evidence of significant population change, and it is believed that if previous figure is correct there are c. 80,000 and c. 20,000 pairs in Britain and Ireland respectively. Population estimates (breeding pairs) in 1997: Europe 3,973,943-4,872,619, Russia 1,000,000-5,000,000 and Turkey 50,000-500,000. Has recently colonized Canary Is, on Gran Canaria and probably Tenerife.

Bibliography. 80. Plain Swift

Apus unicolor

French: Martinet unicolore **German:** Einfarbsegler **Spanish:** Vencejo Unicolor

Taxonomy. *Cypselus unicolor* Jardine, 1830, Madeira.

Forms superspecies with *A. apus* and *A. niansae*; has been considered conspecific with both, and also with *A. barbatus*. In past, considered conspecific with *A. alexandri*. *Shouedenapus myoptilus poensis* formerly treated as race of present species. Monotypic.

Distribution. Canary Is and Madeira; possibly breeds in Morocco.

Descriptive notes. 14-15 cm. Medium-sized swift with even more streamlined outline than *A. apus*, long, deeply forked tail and long thin wings; black-brown outer wing, tail and mantle, with paler, dark brown forehead, rump and underparts beneath indistinct mottled throat-patch. Like *A. apus*, plumage contrast, shade and fringing vary temporally, but appearance averages more barred beneath.

Habitat. Throughout established range, and tentative Moroccan range where frequents sea cliffs, never found far from sea. Occurs over all habitats in Canaries from sea-level to 2500 m; especially common in deep coastal gulleys.

On Madeira from sea-level to highest summit, Pico Ruivo, breeding on rocky islets.

Food and Feeding. Typically insectivorous, but no detailed study. Forms large groups in winter around favoured feeding sites.

Breeding. Season Mar-Aug. Colonial. Nests in variety of natural sites, such as caves and cliffs, where suitable rock niches occur, or under tiles or in holes in man-made structures. Saucer-shaped nest constructed largely from downy seed cases, mainly from *Compositae*, with other plant matter or man-made items less frequently incorporated, agglutinated with saliva with occasional feathers adhered to surface, measuring 100-120 mm across with central depression 10-20 mm wide. 2 eggs; both sexes thought to incubate. Frequently double-brooded.

Movements. Numbers reduced in winter on Canary Is; migrants probably winter mainly in NW Africa, as winter records from Mauritania and N Morocco.

Status and Conservation. Not globally threatened. Restricted-range species; present in Madeira and Canary Islands EBA. Common and apparently stable. Madeira is believed to have 1000-2000 breeding pairs according to 1991 census.

Bibliography. Bannerman (1963), Bannerman & Bannerman (1965), Beaman (1994), Beaman & Madge (1998), Brooke (1971b), Chantler (1993), Cramp (1985), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Driessens (1994), Dunn (1994), Emmerson (1979), Etchecopar & Hùe (1964), Fry *et al.* (1988), Hagemeijer & Blair (1997), Herroelen (1994), Hollom *et al.* (1988), Lack (1956a), Lorenzo & González (1993), Martín (1987), Meininger *et al.* (1990), Moreno (1988), Reese (1997), Rodríguez (1988), Smith (1968), Snow & Perrins (1998), Stattersfield *et al.* (1998), Zehner (1980).

81. Nyanza Swift

Apus niansae

French: Martinet du Nyanza

German: Braunsegler

Spanish: Vencejo de Nyanza

Other common names: Brown Swift

Taxonomy. *Cypselus Niansae* Reichenow, 1887, Kagehi, Lake Victoria.

Forms superspecies with *A. apus* and *A. unicolor*; has been considered conspecific with both, and also with *A. barbatus*. Race *somalicus* formerly considered to belong to *A. pallidus*. Two subspecies currently recognized.

Subspecies and Distribution.

A. n. niansae (Reichenow, 1887) - Eritrea, W Ethiopia, E Uganda, W Kenya and N Tanzania; winter records from N & NE Zaire, NW Tanzania, Somalia, Ethiopia and Kenya.

A. n. somalicus (S. R. Clarke, 1919) - N Somalia and adjacent Ethiopia; some birds winter in Kenya.

Descriptive notes. 15 cm; male 32 g, female 33 g. Medium-sized swift with small head, rakish wings, comparatively short and shallowly forked tail with relatively blunt rectrices; blackest on mantle, outer wing and smallest coverts, showing extreme contrast with pale brown inner wing and greater coverts; brown head and rump less notably paler than inner wing; brown underparts with pale throat. Race *somalicus* averages paler and smaller with more distinct pale throat-patch.

Habitat. Although can be encountered in lowlands, typically occurs in highland areas and associated habitats, gorges, cliff-faces and also human settlements. Arid character of much of

habitat suggests necessity of accessible, relatively wet area as source of abundant food.

Food and Feeding. Prey items recorded: ants 14, flies 7, beetles 2, bugs 1, bees 1 and termites 1. Most active in crepuscular period, though feeds throughout day close to active breeding colonies. Large colony at Hell's Gate, Kenya, forages in daytime high over nearby Lake Naivasha outside breeding season, leaving in early morning and returning at dusk. Gregarious, often associating with other swift species.

Breeding. Laying dates: Eritrea Apr-May, C Ethiopian plateau Apr-Aug, Addis Ababa May-Sept, Kenya Sept; *somalicus* thought to breed in May. Colonial: Addis Ababa colony in a building fluctuated between 20 and 195 pairs over 5 years, though only 10-50 pairs nested at any one time, while at another colony 4-9 nesting attempts per season recorded. Nests in crevices on cliff-faces or in gorges, or in similar niches in buildings. Shallow cup of feathers and grasses agglutinated with saliva, with grass base and possibly some mud incorporated as well as concrete fragments, up to 120 mm wide externally, with internal cup 85-110 mm across and 25-30 mm deep; use of mud seen as tactic to close small space, on to which feathers and sometimes hat bones can be added. Aerial copulation. Clutch 1-3; both sexes incubate, 2-3 periods each during day, one or other on eggs at night with mate beside nest; incubation minimum 19 days; fledging 41 days. Gonad growth suggests first breeding 1 year after hatching.

Movements. In N Somalia present late Mar to late Sept, probably only partially migratory. Addis Ababa colonies present in both rainy seasons, Feb-Apr and Jun-Sept, though this population also only partially migratory. Individuals believed to be wintering birds recorded from Kenya. Other populations resident.

Status and Conservation. Not globally threatened. Generally common to abundant throughout the Rift Valley Highlands. Huge colony at Hell's Gate National Park, Naivasha, Kenya, numbers 10,000's of individuals. Apparently adapts well to man-modified areas, and is common in Addis Ababa.

Bibliography. Archer & Godman (1937-1961), Ash & Miskell (1983b, 1988), Britton (1980), Brooke (1969c, 1970a, 1971b), Brown & Britton (1980), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Duckworth *et al.* (1992), Dyson (1972), Fry (1988e), Fry *et al.* (1988), Grant & Mackworth-Praed (1937), Lewis & Pomeroy (1989), Lippens & Wille (1976), Schwab (1979), Short *et al.* (1990), Smith (1955a, 1955b, 1957), Snow (1978), van Someren (1922), Urban (1984), Urban & Brown (1971), White (1953), Zimmerman, D.A. *et al.* (1996).

82. Pallid Swift

Apus pallidus

French: Martinet pâle

German: Fahlsegler

Spanish: Vencejo Pálido

Other common names: Mouse-coloured Swift

Taxonomy. *Cypselus pallidus* Shelley, 1870, Egypt.

Forms superspecies with *A. barbatus*, *A. berliozii* and *A. bradfieldi*. *A. niansae somalicus* formerly placed in present species. Three subspecies currently recognized.

Subspecies and Distribution.

A. p. brehmorum Hartert, 1901 - W Palearctic from Portugal E to Turkey (except Dalmatian coast), and from Morocco to NW Egypt, including Canary Is and Madeira; winters in Sahel.

A. p. illyricus Tschusi, 1907 - Dalmatian coast and possibly E Italian coast; winters in Sahel.

A. p. pallidus (Shelley, 1870) - Banc d'Arguin through Sahara to Middle East and Pakistan; migratory populations winter in Sahel, with limited wintering coastal Pakistan.

Descriptive notes. 16 cm; 42 g. Large, bulky swift with relatively broad blunt wing-tips, short, fairly shallowly forked tail, broad head and body. Brown, with white throat-patch. Race *brehmorum* larger and darker than nominate, with black-brown outer wing and saddle, smallest wing-coverts minimally paler, greater coverts (including greater primary coverts) and inner wing distinctly paler, entire head, lower back and rump greyer brown and forehead pale grey-brown (pronounced saddle effect), and underparts olive-brown with large, indistinct, triangular pale grey throat-patch contiguous with forehead patch and sometimes strikingly

barred in appearance; *illyricus* slightly larger and darker, with more distinct throat-patch as a result.

Habitat. Throughout much of range associated with coastal sites, especially islets, but occurs in continental zone in C Sahara. Typically found around cliff-faces and gorges, though in many parts of range also in urban areas, where commonly breeds. Forages over many habitats, to 1750 m on Cyprus and 1200 m on Canary Is. Breeds to 1250 m in mountainous plateau of S Italy and to 2700 m in SW Bulgaria. Approximately 42% of Bulgarian population breeds at 1200-1600 m around ski resorts in coniferous woodland, with 38% at 200-500 m in rural and suburban areas.

Food and Feeding. At Gibraltar, 1293 prey items comprised Hymenoptera 56%, Hemiptera 25%, Diptera 12%, Coleoptera 5%, Lepidoptera 1%, and others, including Odonata and spiders, 1%. Small beetles and small flies, including mosquitoes, recorded in Tunisia, and flying ants in Algeria. Gregarious, often associating with other swift species.

Breeding. Laying dates: Israel, Mar-May; Morocco and Tunisia, Mar-Jul, with first clutch from Apr and second clutches beginning late Jul, with last fledging mid-Oct; Gibraltar, first clutch from mid-Apr, peaking late May, with second clutches from late Jul and last fledging mid-Oct. Colonial: 48% of colonies on Gibraltar with fewer than 10 pairs, largest 60 pairs; 3-300 m between colonies; lower level of mate and nest-site fidelity than in *A. apus*. Nests in variety of sites, e.g. caves, cliff-faces, niches, eaves, under tiles, holes in palms, and on Gibraltar forcibly vacated fresh nests of House Martins (*Delichon urbica*); 70% of nests under eaves, 15% in holes in stonework, 7% under gutters and 7% on cliffs. Round nest of straw and feathers agglutinated and adhered to substrate with saliva, 80-100 x 100-120 mm across and 40-50 mm deep, with central depression 25 mm deep, occupied 4-7 days before laying starts. Copulation in flight after soliciting by gliding with raised wings, often after long pursuit. Typically 2 or 3 eggs (1-4 recorded), on Gibraltar first clutches mean 2.9 eggs, second clutches 1.9; both sexes incubate, period 21.5 days; hatching asynchronous; chicks brooded day and night initially, with up to 4 feeding visits per hour; fledging period 46.5 days. Double-brooded. On Gibraltar, fledging rate 53% for first-clutch eggs and 30% for second-clutch eggs.

Movements. Southernmost and some Middle Eastern breeders resident; additional wintering in S Spain and as far N as France recorded, but generally otherwise a medium-distance migrant. Present in France early Apr to mid-Nov, Gibraltar and Morocco late Feb to Oct and Canaries Jan-Sept. Migrates through NW Africa late Feb to early May and Aug-Nov. Spring migration through Eilat, Israel, peaks late Feb to mid-Apr, with autumn migration late May to late Sept, mainly Jun-Jul. Very common passage migrant in Djibouti. Present on Gambian wintering grounds Oct-Dec, as late as Apr in reduced numbers, but in some central N African areas some present all year. Rare visitor to W Liberia late Feb to early Apr. Vagrant S to South Africa. Wintering recorded in India E to Sind.

Status and Conservation. Not globally threatened. Abundant in some areas, including much of N Africa and W Mediterranean. Huge count of 8000-12,000 birds made from an area of cliffs in SE Mali. Locally uncommon in many peripheral areas such as Canaries, Turkey and S France. In 1976, French population thought to be 100-1000 pairs; marked increase in population and range since first mainland breeding in 1950. Single colony of 8000 birds at Sevilla, Spain, in 1986. Stable or possibly slightly increasing European population, with greatest abundance in Spain, Portugal, extreme S France, Corsica, Sardinia, Croatia and Greece; slight decline in Gibraltar and Greece, with Albanian range declining. Population estimates (breeding pairs) in 1997: Europe 21,202-32,893 and Turkey 10-1000. Large colonies in Israel, with 2000 pairs at Har Sedom.

Bibliography. Affre & Affre (1967), Ali & Ripley (1983), Anon. (1988b), Aspinall (1996), Bannerman (1953), Barlow *et al.* (1997), Beaman & Madge (1998), Benson *et al.* (1971), Bernis (1988), Bigot *et al.* (1984), Blankert (1980a), Boano (1979), Boano & Cucco (1989), Boano *et al.* (1993), Bretagnolle *et al.* (1995), Brichetti *et al.* (1988), Brooke (1968, 1969a, 1970a), Burges (1983), Calvert (1984), Casement (1963), Castan (1955), Chantler (1990, 1993), Cheke & Walsh (1996), Colombo & Galeotti (1993), Cramp (1985), Cuadrado *et al.* (1985), Cucco (1992), Cucco & Malacarne (1987, 1995, 1996a, 1996b, 1996c), Cucco, Bryant & Malacarne (1993), Cucco, Malacarne, Orecchia & Boano (1991, 1992), Cucco, Malacarne & Poncino (1994), Diaz, Asensio & Telleria (1996), Driessens (1994), Dudley *et al.* (1996), Dunn & Wilson (1985), Duquet & Frémont (1995), Elgood *et al.* (1994), Evans (1994), Finlayson (1979), Finlayson & Tomlinson (1993), Flaxman (1987), Fry *et al.* (1988), Gatter (1997), Gélouet (1961), Gimpel *et al.* (1986), Goodman & Watson (1983), Goodman *et al.* (1989), Gore (1990), Gory (1995), Gory *et al.* (1995), Grimes (1987), Grimmett *et al.* (1998), Hagemeijer & Blair (1997), Hanby (1985), Harvey (1981a, 1981b), Hazevoet (1995), Heim de Balsac (1949/50), Hirschfeld (1995), Iankov (1991), Jennings (1995), Kainady (1976), Kennedy (1986), Kroymann & Kroymann (1991), Lack (1958c), Lack & Lack (1951a), Ladbroke & Smart (1984), Laferrère (1972, 1974), Lethaby (1987), Malacarne & Bertolo (1994), Malacarne & Cucco (1990, 1991, 1992), Malacarne, Cucco & Bertolo (1994), Malacarne, Cucco & Clemente (1987), Malacarne, Cucco & Orecchia (1992), Malacarne, Palomba *et al.* (1989), Mayaud (1951), Mazzotto *et al.* (1996), Mingozzi *et al.* (1988), Molteni (1964), Morgan (1990), Neubaur & Trettau (1959), O'Toole (1994), Ojalvo (1993), Palomeque *et al.* (1980), Penlop *et al.* (1997), Piacentini *et al.* (1996), Pulcher (1985), Purroy (1997), Randi & Boano (1993), Roberts (1991), Rodríguez de los Santos & Rubio (1986), Shirihi (1996), Short & Horne (1981), Smart (1984), Snow (1978), Snow & Perrins (1998), Telleria (1981), Thibault *et al.* (1987), Thiollay (1974), Thonnérieux (1987), Walbridge & Cade (1986), Wallace (1961), Wassink (1980), Welch & Welch (1984), Yeatman (1976).

83. African Swift

Apus barbatus

French: Martinet du Cap **German:** Kapsegler **Spanish:** Vencejo de El Cabo
Other common names: Black Swift(!), African Black Swift; Fernando Po Swift (*sladeniae*); Madagascar Swift (*balstoni*)

Taxonomy. *Cypselus barbatus* P. L. Sclater, 1865, Cape of Good Hope.

Forms superspecies with *A. pallidus*, *A. berliozi* and *A. bradfieldi*. Has been considered conspecific with *A. apus* and also with *A. unicolor* and *A. niansae*. Races *sladeniae* and *balstoni* (possibly with *mayottensis*) sometimes treated as two further distinct species. It has been suggested that if race *hollidayi* can remain a distinct breeding population despite presence of migratory nominate race during local breeding season, then it may prove to be a separate species. Current knowledge about taxonomic status of *glanvillei*, *sladeniae* and *serlei* to some extent compromised by scarcity of specimens; racial identity of population resident in N Liberia unknown, but may prove to be *sladeniae*; in contrast, *sladeniae* might even be applicable only to birds of Bioko. Nine subspecies recognized.

Subspecies and Distribution.

A. b. glanvillei Benson, 1967 - Sierra Leone.

A. b. sladeniae (Ogilvie-Grant, 1904) - SE Nigeria, W Cameroon (Mt Kupe), Bioko and W Angola; possibly this race in N Liberia.

A. b. serlei de Roo, 1970 - W Cameroon (Bamenda).

A. b. roehli Reichenow, 1906 - E Ethiopia, NE Uganda and Kenya to Malawi and E Zaire; also Sombo in NE Angola.

A. b. hollidayi Benson & Irwin, 1960 - Victoria Falls, on Zambia/Zimbabwe border.

A. b. oreobates Brooke, 1970 - Melsett to Mashonaland (Zimbabwe) and Mt Gorongosa (Mozambique).

A. b. barbatus (P. L. Sclater, 1865) - South Africa, and may occur W into mountainous areas of Namibia; wintering grounds unknown.

A. b. mayottensis (Nicoll, 1906) - Comoro Is.

A. b. balstoni (Bartlett, 1880) - Madagascar.

Descriptive notes. 16 cm; 42 g. Large, bulky swift, with broad blunt-tipped wings, short, shallowly forked tail and heavy body; black underparts with whitish throat-patch; black outer wing and saddle; notable inner wing contrast, and paler forehead and rump. Contrast between inner and outer wing less than in *A. niansae*. Race *glanvillei* slightly darker; *sladeniae* very dark, especially on throat, which lacks any paler feathers in some birds; *serlei* darker, lacking blue gloss on mantle and with underpart fringing more restricted; *roehli* smaller and darker; *hollidayi* paler with uniform wing-coverts; *balstoni* similar to *roehli*.

averaging darker with more uniform mantle, smallest coverts and outer wing; *mayottensis* slightly browner than *balstoni*.

Habitat. Primarily in moist mountains, typically breeding at 1600-2400 m, less often at 1000 m and below, and also over adjacent, even lowland habitats. Noted at 300-2150 m in Marojejy, Madagascar. Found over all habitats on Comoros. In S Cape and in Madagascar, breeds on sea cliffs.

Food and Feeding. Beetles, ants, termites and bees recorded; c. 12 beetles 8 mm long found in 1 stomach. Forages over forest canopy, and also at lower levels where forest more open with large trees. Gregarious, frequently in flocks up to 100, regularly with other swifts. Noted feeding lower than *A. caffer* or *Tachymarpis melba*. One seen feeding in middle feeding level, 20-30 m, at Kariba, Zimbabwe.

Breeding. Laying Malawi Aug-Sept, Zimbabwe Sept, South Africa Sept-Feb, Madagascar Nov-Mar; in E Africa breeding correlated with cool dry season, mid-year, or rainy seasons; possible *sladeniae* recorded in Liberia were visiting probable nest-site in crack in vertical granite dome, also used by Lesser Striped Swallows (*Hirundo abyssinica*). Red-rumped Swallows (*H. daurica*) and Rock Martins (*H. fuligula*), in late May. Typically colonial, recorded in mixed colony with *Tachymarpis melba*. In E Africa nests mainly in hollows in mature trees, especially cedars (*Juniperus procera*); favours niches in non-granite cliffs, including sea cliffs near Cape Town, in some cases within sea-spray zone, though possible tree-breeding recently recorded. Nest a shallow pad of grass, occasionally seed-down, and feathers, with untidy base and neat, sturdy, yet thin top; materials collected in flight. Clutch 1-2.

Movements. Nominate race present as breeder in South Africa Aug to mid-May, with presumed migration through Kariba, Zimbabwe, in May and Aug, while some probably overfly Botswana. However, wintering recorded from S Cape, Swaziland and Natal. It has been suggested that *balstoni* may be migratory to some extent, with decline in numbers noted in SW Madagascar Apr-Jul and on High Plateau Apr-Sept. Resident in other areas of range. In Natal, altitudinal migration from 1500-2400 m to below 900 m. Situation in Zimbabwe complex, with many "black" swifts present at Victoria Falls Nov-Apr, including small numbers of *hollidayi* and larger numbers of *A. apus*, but majority assumed to be migratory South African population of nominate race. W African race *sladeniae* may be only a vagrant to Bioko, while 2 possible *sladeniae* recorded from Principe in 1997.

Status and Conservation. Not globally threatened. Form *sladeniae* Data-deficient, known from only 10 records. All 3 W African races also known from only a small number of specimens. Locally abundant in South Africa and locally common in E Africa. In Kenya, locally common in W highlands. Restricted race *mayottensis* common in Comoros, where seen throughout; a group of 100 on Grand Comoro (Ngazidja) in early Aug 1981. Race *balstoni* widespread and common in Madagascar, with aggregations of several thousands recorded.

Bibliography. Anderson, M.D. (1994), Anon. (1995g, 1997a, 1998b), Bannerman (1953), Bannerman & Bates (1924), Basilio (1963), Benson (1960, 1967a), Benson & Benson (1977), Benson & Irwin (1960), Benson, Brooke *et al.* (1971), Benson, Colebrook-Robjent & Williams (1976-1977), Broekhuysen (1971), Brooke (1968, 1969a, 1970a, 1971b, 1972d, 1994), Chapin (1939), Cheke & Walsh (1996), Collar & Stuart (1985), Collar *et al.* (1994), Donnelly (1974), Dowsett & Dowsett-Lemaire (1993), Elglood *et al.* (1994), Field (1998), Fry (1988c), Fry *et al.* (1988), Gatter (1993, 1997), Good (1952), Harrison *et al.* (1997), Hockey *et al.* (1989), Hustler (1996), Johnson & Maclean (1994), Lack (1956a), Langrand (1995), Lewis & Pomeroy (1989), Louette (1988a), Maclean (1993), Martin, R. *et al.* (1985), Milon *et al.* (1973), Muller & Herremans (1995), Parker (1971, 1972), Penry (1994), Pérez del Val (1996), Pérez del Val *et al.* (1997), Pinto (1983), Rand (1936), Reichenow (1907), de Roo (1970), Safford & Duckworth (1990), Short *et al.* (1990), Snow (1978), Thompson & Buisson (1988), Traylor (1960), Zimmerman, D.A. *et al.* (1996).

84. Forbes-Watson's Swift

Apus berliozi

French: Martinet de Berliozi **German:** Sokotrasegler **Spanish:** Vencejo de Socotora

Other common names: Berliozi's/Watson's Swift

Taxonomy. *Apus pallidus berliozi* Ripley, 1965, Socotra.

Forms superspecies with *A. pallidus*, *A. barbatus* and *A. bradfieldi*. Birds breeding in SE Somalia (Hal Hambo) are apparently intermediate between nominate and race *benisoni*. Two subspecies recognized.

Subspecies and Distribution.

A. b. berliozi Ripley, 1965 - Socotra.

A. b. benisoni Brooke, 1969 - Somalia; winters S to coastal Kenya.

Descriptive notes. 16 cm; male 37-5 g, female 40 g. Plain brown, with forehead and lores intermediate in shade between *A. apus* and *A. pallidus*. Very like *A. pallidus* in structure and plumage, but slightly darker overall, with less distinct saddle and oily sheen on primaries, secondaries and median upperwing-coverts, and less contrast between inner wing and outer wing, latter particularly important relative to other resident plain *Apus*: slightly paler overall than *A. apus pекinensis*, with larger, whiter throat-patch and oily sheen on upper secondaries and median coverts, and separable in hand by longer average bill length (tomium

18-20 mm in *benisoni*, 16-18 mm in *A. a. pекinensis*) and apparently by P10 being longest (P9 generally longest in *pekinensis*). Race *benisoni* darker and browner than nominate, with more rounded throat-patch, less marked underparts and darker forehead.

Habitat. Generally found in arid landscapes. On Socotra seen over a wide range of habitats, even urban ones; in mountains occurs at 700-1200 m, favouring craggy areas. Coastal breeders nest in cliffs and caves, foraging over stabilized dunes. In Kenya, where non-breeding visitor, seen over coastal lowland forest.

Food and Feeding. Beetles, ants, grasshoppers, termites and bugs recorded. Typically forages in small numbers, c. 10, though flock of 200 recorded.

Breeding. Breeds at Hal Hambo, Somalia, Mar-Sept, or perhaps Dec, though this may be due to disturbance; completed by mid-May on Socotra. Colonial. Nests in holes in ceilings of sea-caves; saucer-shaped or pad-like nest 110-130 mm wide and 30-60 mm deep, sometimes lacking central depression, composed of dry seaweed (*Cymodocea*) agglutinated with saliva to a variety of materials, including sand, feathers, fishing line and plant matter. 2 eggs.

Movements. Race *benisoni* partial migrant, with some wintering on Indian Ocean coast as far S as Kenya, in coastal lowlands, where recorded Oct-Feb from Arabuko-Sokoke and Gede Forests S to Diani, Gazi and Shimba Hills. Otherwise resident. Unidentified *Apus* in Aden during Apr-Jul may prove to be this species.

Status and Conservation. Not globally threatened. Range very restricted. Common at main Socotran breeding site in Hajhir Mts, e.g. 300 recorded in survey, spring 1993. Range may be slightly more extensive than currently thought.

Bibliography. Ash & Miskell (1983b, 1998), Britton (1980), Brooke (1969b, 1969c, 1971b, 1972c), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Dymond (1966b), Evans (1994), Fry (1988c), Fry *et al.* (1988), Jennings (1995), Kirwan *et al.* (1996), Lewis & Pomeroy (1989), Porter, Christensen & Schiormacker-Hansen (1996), Porter, Dymond & Martins (1996), Ripley (1965), Ripley & Bond (1966), Short *et al.* (1990), Snow (1978), Zimmerman, D.A. *et al.* (1996).

85. Bradfield's Swift

Apus bradfieldi

French: Martinet de Bradfield **German:** Damarasegler **Spanish:** Vencejo de Namibia

Taxonomy. *Micropus bradfieldi* Roberts, 1926, Namibia.

Forms superspecies with *A. pallidus*, *A. barbatus* and *A. berliozi*. It has been suggested that resemblance to *Tachymarpis aequatorialis* may be more than superficial, hinting at closer alliance between these forms, which were formerly considered conspecific. Two subspecies recognized.

Subspecies and Distribution.

A. b. bradfieldi (Roberts, 1926) - SW Angola and Namibia.

A. b. deserticola Brooke, 1970 - N Cape (South Africa).

Descriptive notes. 18 cm; 42-5 g. Large swift with structure typical of *A. pallidus* group; relatively pale and lacking distinct saddle; black-brown outer wing and tail contrast with inner wing and paler brown upperparts; indistinct pale throat-patch on grey-brown, heavily patterned underparts. Race *deserticola* slightly darker-bodied, with resultant increase in throat-patch contrast.

Habitat. Occurs over a variety of arid habitats, including true desert and open savanna.

Food and Feeding. Insects, including honeybees (*Apis mellifera*) and termites. Latter particularly important, taken after emergence

precipitated by summer storms. In Namibia, noted resting on ground near hives while catching bees in flight, probably foraging for young at colony 24 km distant.

Breeding. Race *bradfieldi* probably breeds c. Aug-May (laying Apr, Namibia; nestlings Oct, Angola); *deserticola* recorded breeding in South Africa in Dec-Jan, Mar and May. Colonial. Nests in fissures in granite or basalt rocks, old buildings and disused mine workings, possibly also in dead palm fronds. Flat, cup-like nest of vegetable matter, including straw probably taken from nests of Pale-winged Starlings (*Onychognathus naboroupp*), and small feathers; 100 mm long, 105 mm wide and 35-55 mm deep, with central depression averaging 87 x 24 mm; adhered to angle of fissure with saliva. 2 eggs.

Movements. Mainly resident with some dispersal after breeding.

Status and Conservation. Not globally threatened. Commonest swift in C Namibia and generally common throughout range. Believed to have colonized E to Big Hole in Kimberley during 20th century. Formerly classified as South African Red Data species, but no longer applicable.

Bibliography. Anderson, M.D. (1994), Brooke (1968, 1969a, 1969c, 1970a, 1971b, 1971c, 1984), Brooke & Avery (1992), Brown (1989, 1993), Dean & Jensen (1974), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fry *et al.* (1988), Ginn *et al.* (1989), Harrison *et al.* (1997), Lack (1956a), Louit (1980), Mackworth-Præd & Grant (1962), Maclean (1993), Pinto (1983), Ryan & Rose (1985), Snow (1978).

86. Pacific Swift

Apus pacificus

French: Martinet de Sibérie **German:** Pazifiksegler **Spanish:** Vencejo del Pacífico
Other common names: Fork-tailed Swift(!), Pacific Fork-tailed Swift, White-rumped Swift(!), Asian/Large/Northern White-rumped Swift

Taxonomy. *Hirundo pacifica* Latham, 1801, New South Wales.

Forms superspecies with *A. acuticauda*, with which in past occasionally considered conspecific. Four subspecies recognized.

Subspecies and Distribution.

A. p. pacificus (Latham, 1801) - Siberia E to Kamchatka and Japan, S to N China and S Japan; winters in Indonesia, Melanesia, Australia and possibly NE India (Assam, Nagaland, Manipur).
A. p. kanoi Yamashina, 1942 - SE Tibet E to Taiwan; winters in Malaysia, Philippines and Indonesia.
A. p. leuconyx (Blyth, 1845) - outer Himalayas and Assam hills; winters in India.
A. p. cooki (Harrington, 1913) - SE Asia; winters S to N peninsular Thailand.
May also breed (race unknown) in Batan Is (N Philippines).

Descriptive notes. 17-18 cm; male 42.5 g, female 44.5 g. Large swift, with rakish structure, long pointed wings, long, deeply forked tail, and thickest outer tail tapering little from body. Very black upperparts, tail and wings, showing greater contrast between inner wing and outer wing below, with striking white rump band; feathers of underparts broadly white-fringed, though whitish throat-patch can be indistinct. Race *kanoi* blacker, with rump-patch and throat-patch smaller, greyer throat and more streaked and less deeply forked tail; *leuconyx* similar to *kanoi* but smaller; *coki* smallest race, with most streaking on throat and

rump and narrowest underpart fringing.

Habitat. Occurs over a vast range of habitats, both breeding and wintering, from low Arctic to pebbles, often around human habitation. Winters mainly in lowlands. Recorded breeding at 2300 m in Pakistan and c. 3500 m in Tibet; recorded to 3800 m in Nepal and may forage as high as 4000 m; occurs over temperate, subtropical and broad-leaved forest between 1300-2400 m in C Bhutan; occurs from sea-level to 3000 m in Japan.

Food and Feeding. On Chinese breeding grounds, prey recorded from 9 insect orders, Diptera predominating. Flying termites recorded for race *leuconyx*, and bees in Myanmar in winter. In Siberia where sympatric with *A. apus*, feeds at dusk for much longer period, to midnight or 1:00 am. Typically forages higher than congeners, especially in winter. In Malaysia, mean foraging heights 184.5 m in forested habitats and 133.5 m in open habitats, most preferring former, representing higher strata in mixed flocks with *Hirundapus*, *A. nipalensis* and to lesser extent *Rhaphidura leucopygia*. Gregarious, regularly in large flocks, though most often found foraging in small groups of 3-5.

Breeding. Breeds Langtang in Nepal, Mar-May, Himalayas Apr-Jul, and Japan Jun-Aug; eggs recorded from late May on Yellow Sea islands, from early to middle Jun in China, from mid-Jun in L. Baikal region, and mid-Jun to mid-Jul in Siberia; nestlings being fed in mid-Jul near Ust-Karsk. Colonial. In Japan, nests in mountainous cliffs and caves on islands; nest is half-cup of vegetable matter agglutinated with saliva and similarly adhered to sloping face of cliff fissure or cave of building; will utilize nest of Nepal House-martin (*Delichon nipalensis*); nest material taken in flight and from ground. Clutch 1-3; incubation 17 days; both adults take equal part in all duties at nest; fledging period 40-5 days. On Cheniushan I in Yellow Sea, where conditions apparently highly suitable, hatching success 73.5%, fledging success 63.6%, with average of 1.24 young produced per pair annually.

Movements. Nominate race a long-distance migrant, while 3 more S races mainly resident or short-distance migrants; race *coki* thought to be resident, but has occurred in winter in Malay Peninsula; *kanoi* has occurred in winter in Philippines and Malaysia; *leuconyx* may be dispersive resident, recorded throughout Indian Subcontinent. Nominate form winters in Indonesia, Melanesia and Australia, where common Oct-Apr; recorded Cape York Peninsula, N Australia, with *Hirundapus caudacutus* in Jul, presumably non-breeding birds. Arrives in Japan from late Mar, most arriving in Honshu mid-Apr and Hokkaido early May. First arrivals in far E Siberia from late Apr to early May, appearing *en masse* in NE Mongolia late May to early Jun. Leaves Yakutia in mid-Aug, E Mongolia Aug, L. Baikal late Aug, Japan from late Sept with migration through Oct and early Nov. Regular passage migrant in Java, though relatively few migrant records from Borneo and Sumatra. Recorded across Wallacea, rarely as winter visitor but mainly as passage migrant: Sulawesi Sept-Oct and Jan-Mar, Halmahera late Sept and early Apr, Buru late Nov and early Dec, Flores mid-Aug to mid-Apr, Timor Sept-Nov and Mar, and Aru Is early Apr. Migrates through Malay Peninsula mid-Sept to mid-Nov and late Feb to late May, recorded Talaud early Oct and S New Guinea mid-Oct to late Dec. Large numbers migrate through Riau Archipelago, in Strait of Malacca, late Apr. Often seen with *Hirundapus* species on passage. First mainland record in Cochinchina as recently as 1996, and probably under-recorded on passage throughout Indochina. Recently recorded in mid-winter in S Sumatra, where largest migrant group c. 220 moving S through Serkap early Oct. Vagrant within Russia W to Urals, to Britain Jun 1981 and May 1993, to Alaskan islands at least 10 times, Jun-Sept, and to Macquarie I in S Tasman Sea.

Status and Conservation. Not globally threatened. Rare in Pakistan, but not uncommon in other Himalayan areas. Generally common throughout rest of breeding and wintering range. Large colony on one Yellow Sea island numbers over 8000 birds after breeding.

87. Dark-rumped Swift

Apus acuticauda

French: Martinet de l'Assam **German:** Glanzrückensegler **Spanish:** Vencejo de los Khasi
Other common names: Khasi Hills/Dark-backed Swift

Taxonomy. *C. [ypselus] acuticauda* [sic], Jerdon, 1864, India (= Nepal?).

Forms superspecies with *A. pacificus*, of which in past occasionally considered a race. Population from Blue Mts, in Lushai Hills of S Assam, described as race *rupehandi*, but claimed differences in plumage do not hold good. It is also suggested that, if a series of specimens were available from Thailand, they might show that population to represent a separate form. Monotypic.

Distribution. Breeds with certainty around Cherrapunji and Lilancote, in Khasi Hills (NE India); also thought to breed in Lushai Hills, in Mizoram (extreme S Assam), where series of specimens collected in May. Recently recorded in Bhutan; may occur in Myanmar and (1 specimen) Nepal. In Thailand, to date only known by winter records from NW.

Descriptive notes. 17 cm. Large swift with rakish structure very like *A. pacificus*; outer tail slightly less thickset as outer rectrices strongly emarginated. Upperparts black; underparts heavily marked with broad white fringes; throat-patch indistinct, more heavily streaked and probably averaging darker than in *A. pacificus*.

Habitat. Deep gulleys and cliffs in the very wet Khasi Hills.

Food and Feeding. Not known.

Breeding. Season end Mar to end Apr. Colonial. Cup-like nest of grass and feathers agglutinated with saliva, on ledge in cliff fissure.

Clutch 2-3, though 4 recorded.

Movements. Winter records from NW Thailand indicate short-distance migration, although birds concerned may possibly represent an unknown population. Recorded from Bhutan in springs of 1996 and 1997; not recorded from Andaman Is, and some doubts surround origin of Nepalese record. May be summer visitor only to breeding zone.

Status and Conservation. VULNERABLE. Restricted-range species; present in Eastern Himalayas EBA. Apparently small population and very limited known range imply species at risk, though lack of recent information may mask true status. Extensive research and survey work required.

Bibliography. Ali & Ripley (1983), Baker (1934a), Brooke (1969d), Collar & Andrew (1988), Collar *et al.* (1994), Grimmett *et al.* (1998), Inskipp, C. & Inskipp (1991), Inskipp, T. *et al.* (1996), Jerdon (1863-1864, 1871), Koelz (1954), Lack (1956a, 1958e), Lekagul & Round (1991), Ripley (1982), Robson (1996b, 1997d), Smythies (1986), Stattersfield *et al.* (1998), Vaurie (1959).

88. Little Swift

Apus affinis

French: Martinet des maisons **German:** Stubbstärtssegler **Spanish:** Vencejo Moro
Other common names: House Swift(!)

Taxonomy. *Cypselus affinis* J. E. Gray, 1830, Ganges.

Forms superspecies with *A. nipalensis*, with which often considered conspecific; separation based mainly on consistently shorter, less forked tail and broader rump band, combined with potential sympatry in Himalayas. Birds of sub-Saharan Africa formerly treated as race *abessynicus* [sic], and those of coastal Limpopo and Transkei as race *gyratus*. Six subspecies recognized.

Subspecies and Distribution.

A. a. galilejensis (Antinori, 1855) - NW Africa E to Pakistan, and S of Sahara in E Sudan, Eritrea, Ethiopia and NW Somalia.
A. a. aerobates Brooke, 1969 - Mauritania E to Somalia and S to Transkei (E South Africa).
A. a. bannermani Hartert, 1928 - Bioko, Principe and São Tomé, in Gulf of Guinea.
A. a. theresae Meinertzhagen, 1949 - W & S Angola to S Zambia and S through S Africa.
A. a. affinis (J. E. Gray, 1830) - S Somalia to N Mozambique (including Zanzibar and Pemba), and E to India S of Himalayas and E of Pakistan; some birds winter in India and presumably Africa.
A. a. singalensis Madarász, 1911 - S India and Sri Lanka.

Descriptive notes. 12 cm; male 25 g, female 25 g. Small swift with relatively chunky body, blunt wing-tips and square tail; black above, with slightly paler forehead and uppertail-coverts, and very distinct broad white rump-patch, which extends onto lower part of flanks; underparts blackish apart from inner wing and rounded white throat-patch. Differs from other *Apus* in square-ended tail; rump-patch broader than in *A. nipalensis*. Race *galilejensis* very pale, especially on tail-coverts and forehead; *aerobates* darker than nominate, especially on wings and tail, with coastal population between Limpopo and Transkei ("*gyratus*") darkest and

largest within subspecies; *theresae* very like *galilejensis* but with slightly darker uppertail-coverts; *bannermani* darkest race, with heaviest throat streaking; *singalensis* blacker than nominate, especially on head and uppertail-coverts, some showing slight tail-fork.

Habitat. Occurs over a wide range of habitats and latitudes, though less frequently in truly arid regions, and usually close to human habitation. In Kenya, recorded to 3000 m. In Botswana, absent from areas lacking surface water as a result of permeable sandy soils. May shun high-altitude grassland in South Africa because of competition from wintering Northern House-martins (*Delichon urbica*).

Food and Feeding. Flies, termites, ants, beetles, grasshoppers and a dragonfly recorded in Africa, and Diptera, Hemiptera, Coleoptera, Hymenoptera and airborne Arachnida in India. Rarely feeds very low but often forages at great height, particularly, it is believed, during winter in S Africa. Highly gregarious, often with other Apodidae. Noted feeding in flocks of up to 50 on huge columns of "Chilli" white aphids (*Myzus persicae*) in S India. Forages as far as 15-20 km from nest-site on occasions.

Breeding. Feb-May and Aug-Oct in Mauritania, Oct-Jul in Senegambia, avoiding rainy season, and year-round in W African rainforest areas, including Liberia, where Aug-Sept lull; laying dates Mar-May and Sept-Oct in Sierra Leone, May and Dec in Nigeria (perhaps year-round, at least in S),

Feb in Bioko, Jun-Jul in São Tomé, Jun in Chad, Mar and May in Sudan, and Mar-May and Jul-Aug in Ethiopia; E African breeding coincides with rainy seasons, Feb in Malawi, Oct and Mar-Apr in Zambia, Sept-May in Zimbabwe; Aug-Apr in South Africa, with two-thirds Sept-Nov; nominate race breeds year-round in India except Nov-Feb; *singalensis* breeds mainly Mar-Jul; *galilejensis* from Feb/Mar to Oct in Karachi, Mar-Jul in NW Africa, and from early May in Nura-Tau range (Uzbekistan); in Israel, first brood hatches late Mar to early Apr and second Jun-Jul; nestlings being fed mid-Aug, Turkmenistan. Two breeding seasons recorded in Kenya and Gujarat as result of bimodal rainy season. Colonial, typically fewer than 30 nests, though colony of 95 recorded and c. 1000 nests from 1 building in Ghana; nesting alongside Eurasian Crag-martin (*Hirundo rupestris*) reported; 2-3 females may lay in 1 nest; solitary breeding recorded. Cliff sites and abandoned swallow (*Hirundo*) nests can be employed and forcible eviction noted, but typically nests on man-made structure in angle between roof and wall; eviction by House Sparrows (*Passer domesticus*) recorded. Nest a sturdy, untidy, yet internally neat and smooth, hemispherical "bag" of vegetable matter, mainly grass, down and small twigs, with feathers, agglutinated with saliva; built in dense, often overlapping clusters with up to 3 entrances, sometimes communal; needs perch to cling to while building. Clutch 1-3, 3 in Kenya and 2 in South Africa, usually completed over 4-5 days, all eggs in colony laid within 10 days; incubation stints short and irregular until clutch completed, and then initially for up to 90% of day, by both parents typically at intervals of less than 90 minutes; clutch unattended c. 3 times per day, sometimes for up to 1 hour (usually less than 8 minutes); incubation 22-24 days. Double-brooded, second clutch laid on fledging of first young; in Zanzibar 1 pair laid 6 clutches over 21 months, implying near-constant breeding in some equatorial areas.

Movements. Resident throughout tropics; majority of northernmost (W Palearctic) and southernmost (S African) populations wholly or partly migratory. Present Turkey Mar-Sept only, and summer only also in Tajikistan, Uzbekistan and Turkmenistan, otherwise partially migratory only in Middle East and N Africa, though noted on passage in Chad during Oct. E populations of *galilejensis* may migrate through Arabia to Africa. Complex picture emerges from Israel, where resident N Israeli population disperses up to 100 km during Oct-Mar into areas where it does not breed; small passage, presumably from outside Israel, mid-Sept to mid-Dec and early Feb to mid-May. Populations in S Africa, C Zimbabwean plateau and Freetown, Liberia, may be partly migratory, but this is equivocal and may be result of apparent reductions in numbers caused by changes in roosting behaviour, making species less conspicuous; however, coastal migration recorded in Liberia at beginning of dry season. Recently recorded Antananarivo, Madagascar, during Sept and Nov; at least one record on Maldives, flock of 7 in Dec. Accidental but increasingly recorded in Europe; 5 records in Spain up to early 1990's and at least as many since; 4 in Portugal up to Jun 1998, with first as recently as 1995; Italy 2, Malta 8, Britain and Ireland 9 (May-Nov) and Sweden 4 (Jun-Nov) up to early 1990's, and recent increase in British records (5 in 1997 and 3 in 1998).

Status and Conservation. Not globally threatened. Scarce to locally common in W Palearctic, though often abundant in towns and cities in tropical range. Although generally common and locally abundant in sub-Saharan Africa and India, more local in rural areas. Huge population increase in Africa during 20th century due to increasing use of buildings; in South Africa recorded only once in 19th century, though expanded rapidly to become common by 1930's, with continued expansion to present day; very similar story from Liberia, where expansion followed mass forest destruction. Israeli population believed to number in low thousands of pairs. In Saudi Arabia commonest in Asir highlands. Evidence of genuine increase in W European records in recent years, and possible breeding in S Spain in 1995, when 2 seen flying around a rocky area in Sierra de la Plata, near Tarifa, occasionally entering holes; other recent records from this area, which also holds small breeding population of *A. caffer*.

Bibliography. Abdullahi (1965b), Ali & Gadgil (1975), Ali & Ripley (1983), Andayani *et al.* (1993), Anon. (1996c, 1997a), Ash & Miskell (1998), Atkinson, Dutton *et al.* (1994), Bannerman (1932, 1953), Barlow *et al.* (1997), Beaman (1994), Beaman & Madge (1998), Benson & Benson (1977), Benson *et al.* (1971), Blincow *et al.* (1992), Bradley (1993), Broekhuysen (1971), Brooke (1963, 1965, 1968, 1969a, 1971e, 1971f, 1974b), Brooke & Vernon (1961), Brudenell-Bruce (1958), Bunting (1987), Carr (1984), Chantler (1993), Chantler & Driessens (1995b), Chari *et al.* (1983), Cheke & Walsh (1996), Chittenden (1978), Christy (1988), Clancey (1980c), Collins & Naik (1975), Comyn (1938), Cramp (1985), Dowsett (1977b), Dowsett & Forbes-Watson (1972), Driessens (1994), Dudley *et al.* (1996), Elgood *et al.* (1994), Étiéhouart & Hue (1964), Evans (1994), Ferguson (1955), Friedmann (1930), Fry *et al.* (1988), Gatter (1997), George (1959), Ginn *et al.* (1989), Goodman *et al.* (1989), Gore (1990), Grimes (1987), Grimmett *et al.* (1998), Harrison *et al.* (1997), Hirschfeld (1995), Hockey *et al.* (1989), Hue & Étiéhouart (1970), Ingram (1972), Inskipp *et al.* (1996), Ivri *et al.* (1990), Jennings (1995), Jones & Tye (1988), del Junco & González (1966), Kirkpatrick (1950), Knyshtaus (1993), Laferrière (1972), Langrand (1995), Langrand & Sinclair (1994), Lewis & Pomeroy (1989), Long (1963), Luleyeva (1993), Lunais (1984), Maclean (1993), Moreau (1942a), Morel & Morel (1962), Naik, R.M. & Naik (1965a, 1965b, 1969), Naik, R.M. & Razack (1963, 1967a, 1967b), Naik, R.M. & Shivanarayana (1969a, 1969b), Naik, S. & Naik (1963, 1966), de Naurois (1972, 1994b), Pakenham (1979), Penny (1994), Pepler (1991), Pérez del Val (1996), Phillips (1963, 1978), Pinto (1983), Rahmani *et al.* (1994), Rand (1951b), Razack (1968), Razack & Naik (1965, 1968, 1970), Reuter *et al.* (1980), Roberts (1991), Rudebeck (1980), Salvan (1968), Serle (1939, 1950), Shirihai (1996), Short *et al.* (1990), Skerrett (1996), Snow (1978), Snow & Perrins (1998), Stepanyan (1990), Thirumurthy & Krishna Doss (1981), Tornielli (1977), van der Vliet (1998), Zhao Zhengjie (1995), Zimmerman, D.A. *et al.* (1996).

89. House Swift

Apus nipalensis

French: Martinet malais **German:** Haussegler **Spanish:** Vencejo Oriental
Other common names: Little Swift(!), Malay House Swift

Taxonomy. *Cypselus Nipalensis* Hodgson, 1837, central region of Nepal.

Forms superspecies with *A. affinis*, with which often considered conspecific; separation based mainly on consistently longer, more forked tail and narrower rump band, combined with potential sympatry in Himalayas. Four subspecies recognized.

Subspecies and Distribution.

A. n. nipalensis (Hodgson, 1837) - Nepal E to SE China (Fujian) and Japan, S through Assam and SE Asia, and also N Philippines.

A. n. subfuscatus (Blyth, 1849) - Malay Peninsula, Sumatra including Riau Archipelago and Belitung, Anambas, N Natunas and Borneo.

A. n. fuscatus Brooke, 1971 - Java and Bali.

A. n. kuntzi Deignan, 1958 - Taiwan.

Also occurs in Sulawesi and Lesser Sundas, where population may refer to *subfuscatus* or *fuscatus*.

Descriptive notes. 15 cm. Very similar in size and structure to *A. affinis*, but tail averages longer and has slight, though usually discernible, fork; blacker than *A. affinis*, notably on head and tail-coverts, with narrower white rump band. Race *subfuscatus* even blacker than nominate, especially on upper head; *fuscatus* has deepest tail-fork and browner underparts; *kuntzi* intermediate between nominate and *subfuscatus*, with most heavily streaked rump of any subspecies.

sometimes with other Apodidae and hirundines. In Malaysia in Feb-Jul forages in high strata (over 30 m), with mean heights of 185 m over forested areas and 114.5 m over open areas; preference for forest during Feb-Mar, reversed in Apr.

Breeding. In Myanmar, breeds any time between Feb and early Oct, with most nest-site selection in late Mar, nest-building in Apr, laying in May, hatching in Jun and most nestlings fledged by Jul; in Japan, breeds Apr to late Nov, with hatching peaks late May to early Jun, late Jul to early Aug and late Sept to early Oct; possible prospecting in late Jun, Batangas (Philippines); occupied nests from mid-Dec to mid-Aug, Malay Peninsula; eggs Mar-Apr in Sumatra; nest completed by early Feb with fledging in late Jun, Borneo. Colonial, with breeding synchronized within colony. Typically nests in angle between roof and wall in man-made structure, often in seemingly dangerously accessible sites where human population tolerant; in Yunnan at elevation of 3.6-15.5 m, average 8.1 m; old nest of Striated Swallow (*Hirundo striolata*) used on Flores. Large untidy hemispherical nest "bags" in overlapping clusters, constructed of vegetable matter and feathers, sometimes with artefacts such as rags incorporated, agglutinated and adhered with saliva. Clutch 1-5, mean 3.1; incubation 18-26 days, average 21.1; mean of 26 feeding visits per day, range 8-55; fledging period 36-51 days, average 43.6. Typically raises more than 1 brood per year, with 3 broods in Japan. Hatching success 89.5%.

Movements. Some N populations undertake poorly studied winter movements, with records during this season in Indian Subcontinent. Believed to be a winter resident in Luzon. Recorded in N Australia.

Status and Conservation. Not globally threatened. Abundant over most of range, though level of abundance appears to vary considerably. Common on Sumatra but rather locally distributed. Rare and local in Philippines. Uncommon and highly localized in Japan, where first recorded in 1965, but range expanding since 1970's and 1980's following arrival of Red-rumped Swallows (*Hirundo daurica*), in whose old nests it breeds. Recent colonist in Brunei, where 3 colonies by 1977, but expansion very slow as only 1 additional colony found since then. Recent colonist also in Wallacea, first recorded with certainty in 1978 on Sulawesi, where scarce and local resident in N & S. Similar story from Lesser Sundas, where recorded on Flores since 1986 and on Timor in 1993, and colony of 50 birds on Sumba in Jun 1994.

Bibliography. Abdullahi (1965b), Ali & Ripley (1983), Ali *et al.* (1996), Andayani *et al.* (1993), Biswas (1974), Brazil (1991), Brooke (1971g), Chantler (1993), Clancey (1980c), Coates & Bishop (1997), Collins & Naik (1975), Deignan (1945), Dickinson *et al.* (1991), Finch (1975), Grimmett *et al.* (1998), He Xiaoru (1985), Hellebrekers & Hoogerwerf (1967), Higgins (1999), Holmes, D.A. 90. Horus Swift

Apus horus

French: Martinet horus **German:** Horussegler **Spanish:** Vencejo Horus
Other common names: Toulson's Swift ("toulsoni"); Loanda Swift (*fuscobrunneus*)

Taxonomy. *Cypselus affinis* var. *Cypselus Horus* Heuglin, 1869, north-east Africa.

Taxonomic status of form "toulsoni" of NW Angola and Zimbabwe is highly controversial, and it has been considered a full species, but is probably best treated as a dark morph within nominate race. Two subspecies currently recognized.

Subspecies and Distribution.

A. h. horus (Heuglin, 1869) - C Ethiopia, CS Kenya and N Tanzania, and NW Uganda to Burundi and E Zaire; Zambia to SW Cape (South Africa); more isolated populations in Nigeria, N Cameroon, W Chad, W & EC Sudan, extreme W Zaire and NW Angola.

A. h. fuscobrunneus Brooke, 1971 - SW Angola.

Descriptive notes. 15 cm; 26 g. Small, fork-tailed swift, black-brown with broad white rump-patch, white throat-patch. Differs from *A. affinis* in larger size, forked tail and relatively paler underwing-coverts; tail broader, relatively shorter and less deeply forked than in *A. caffer*. Race *fuscobrunneus* has dark brown rump, smaller, greyer throat-patch, lacks distinct gloss to plumage and has relatively paler uppertail-coverts and head; "toulsoni" morph similar to this subspecies but generally darker; intermediates between "toulsoni" and typical nominate birds have been seen in Zimbabwe.

Habitat. Correlates with that of the bee-eaters (Meropidae), kingfishers (Alcedinidae) and martins (Hirundinidae), among which it nests; consequently, often seen around sand banks, feeding over wide range of adjacent habitat. In Kenya, utilizes colonies of White-fronted Bee-eaters (*Merops bullockoides*) and has a similar range. Breeds at 1600-2000 m in C Kenya.

Food and Feeding. Termites, flies, beetles and ants recorded. One food ball contained 204 insects: 78 jassid, 1 fulgorid and 5 heteropteran bugs, 5 Neuroptera, 95 Lepidoptera, 3 Diptera, 1 wasp, 1 beetle and 15 indeterminate. Another contained 12 spiders and 477 insects of 15 families: beetles, butterflies, flies and wasps, of which 77% Cicadellidae. In Kenya, a complete bolus of 363 prey items and a partial bolus of 33 comprised 79% termites (Termitidae), planthoppers (Cicadellidae and Delphacidae) and ants (Formicidae). Foraging level in mixed flocks typically between lower *Cypsiurus parvus* and higher *A. caffer*; this was apparent at Kariba, Zimbabwe, where fed in groups

of 4-10 within same stratum, 20-30 m, as Mosque Swallow (*Hirundo senegalensis*). Occasionally feeds at highest level, 30-40 m, when this not already occupied. Forages in small flocks, up to 30, often with other swifts or hirundines.

Breeding. Breeds Chad Nov-Feb, Sudan Mar-Jun; egg-laying Jun in Ethiopia, Apr-May in Malawi, Aug-Sept in Zambia, all year but mostly Nov-Feb in Zimbabwe, Jan-May in Transvaal, Nov-Dec and Mar-Apr in Cape; in Zimbabwe breeds in hot wet months Oct-Apr above 1000 m, and in cool months Apr-Sept below 1000 m. Nests solitary; although not genuinely colonial, also in small groups typically of up to 12 pairs, sometimes many more, often scattered within colonies of bee-eaters (Meropidae) or sand martins (*Riparia*), grouped nesting therefore believed to result from utilizing nest-holes of colonial species. Apparent breeding behaviour noted from a cave in coastal sandstone cliffs, SW Cape. Uses deserted nests of burrowing species, namely bee-eaters, kingfishers (Alcedinidae), Ground Woodpecker (*Geocolaptes olivaceus*), Banded Martin (*Riparia cincta*) and probably Southern Anteater-chat (*Myrmecocichla formicivora*), typically in riverbanks; eviction not recorded, though may lose nest to African Pied Starlings (*Spreo bicolor*); 1 burrow was 45 cm long, with narrow entrance and terminal disc-shaped nesting cavern, 30 x 40 cm and 6 cm high. Nest is thin platform of vegetable matter agglutinated with saliva to hair, feathers, occasionally rags; windblown grass collected. Copulates at nest. Clutch 1-4, average 2 in Zimbabwe and 3 in South Africa; incubation c. 28 days; average feeding interval 54 minutes, mean weight of food pellets 1 g; fledging period c. 6 weeks.

Movements. Populations breeding in South African and Zimbabwean high veld winter elsewhere, possibly in Zimbabwean low veld, though resident in some low-lying tropical parts of S Africa S to NE Transvaal. Similar movements, thought to be localized, perhaps altitudinal, occur in parts of E Africa, e.g. present at Mau Narok, Kenya, at 3000 m late Apr to early Jul; C Kenyan population as a whole present only Mar-Sep, with some records E of breeding range Oct-Dec. Believed to be dry-season visitor in Zambezi Valley. In Natal, makes altitudinal migration from 1500-2400 m to below 900 m. **Status and Conservation.** Not globally threatened. Locally common in suitable habitat over much of range, and abundant in some C Ethiopian highland sites. Range has increased following colonization of buildings by hirundine hosts. One Kenyan colony at Nakuru numbered "several hundred" pairs in 1978. Recently recorded for first time from Niger.

91. White-rumped Swift

Apus caffer

French: Martinet café **German:** Kaffernsegler **Spanish:** Vencejo Café
Other common names: African White-rumped Swift

Taxonomy. *Cypselus Caffer* Lichtenstein, 1823, South Africa.

Population of N Angola and lower Congo formerly separated racially as *ansorgei*, but merely one of darkest-headed populations and no longer considered a valid race. Birds of tropical zones (excluding migratory populations in extreme N and S) claimed to average shorter-winged, and are sometimes recognized as racially distinct (*streubelii*), but variation in wing length apparently clinal, increasing from N to SW. Monotypic.

Distribution. S Spain, E Portugal and C Morocco; Senegambia, N & E Sierra Leone and (probably breeding) NW Liberia, then C Ivory Coast E to Somalia and S to South Africa; S Gabon S to C Namibia (Windhoek). Winter range of migratory populations unknown.

Descriptive notes. 14 cm; 22 g. Smallish, very graceful swift with long, deeply forked tail, very heavily emarginated outer rectrices, often held tightly closed for long periods, and long slim wings. Deeply black plumage with narrow, though highly contrasting, white rump, small white throat-patch, and slightly paler forehead and superciliary area; when remiges fresh, white trailing edge to secondaries visible.

Habitat. Occurs over a wide range of habitats, from arid savanna and Mediterranean scrub to equatorial forest. Habitat dictated by preferences of nest "hosts": *A. affinis*, and Lesser Striped Swallow (*Hirundo abyssinica*), Greater

Striped Swallow (*H. cucullata*), Rufous-chested Swallow (*H. semirufa*), Wire-tailed Swallow (*H. smithi*), Rock Martin (*H. fuligula*), Angolan Cliff Swallow (*H. rufigula*) and Red-rumped Swallow (*H. daurica*). Often around urban areas in sub-Saharan Africa, but not yet in W Palearctic (though will nest in disused buildings). In Morocco, occurs from sea-level to 2500 m.

Food and Feeding. Three food balls contained a cerropid bug and 33 winged ants averaging 8 mm in length, a number of winged fire ants (*Solenopsis puncticeps*), some still alive, 10 spiders, and 98 other insects comprising 17 families of flies, bugs, beetles and wasps, of which c. 75% by weight were the leafhopper *Glossocratus afzeli*. Other recorded prey items include termites, chalcid wasps (Chalcidoidea), bees, Lepidoptera and weevils (Curculionidae). Commonly associates with other Apodidae, and less often within W Palearctic range with *H. daurica*. Occurs within the highest feeding level at Kariba (Zimbabwe), 30-40 m.

Breeding. In Spain breeds from late May; laying dates May in Morocco, Jul in Senegambia, Apr and Jun-Jul in Nigeria, Feb in Sudan, May-Jun in Ethiopia, May and Jul in Zaire, Jan-Feb, Aug and Oct in Angola, Aug-Dec in Zambia, Sept in Malawi, Aug-Apr in Zimbabwe, Nov-Feb in Namibia, Aug-Mar in Transvaal, with South African peak Oct-Jan. Loosely colonial or solitary, maximum colony size 15-20; minimum distance between nests 2.5 m in South Africa and 25 m in Spain; loyal to nest-site for at least 9 years and to mate for at least 3. Typically uses disused *A. affinis* or certain swallow (*Hirundo*) nests, though niches in rock-faces or buildings sometimes used; eviction of

swallows involves repeated attacks lasting 3-5 minutes, several times during day, with 4-6 swifts clinging to entrance while owner in occupation; other strategy is to occupy recently completed nest when builder leaves and then remain inside, lining entrance with feathers to hinder entry. In disused nests, uses feathers and down adhered with saliva as lining; in rock sites, shallow cup of feathers and vegetable matter agglutinated with saliva; under eaves, nests only against masonry; typically uses retort-shaped nests, though more open ones may be adopted with suitable adjustment involving building of side walls. Clutch 1-3 eggs, usually 2, laying interval 38-72 hours; sexes share nest duties equally; time spent incubating highly variable, typically 17-90%; average incubation period 21 days in Tanzania and 22-5 days in South Africa, second egg hatching up to 30 hours after first; chicks soon after hatching very active, later moving within cavity up to 2-3 m from nest; eyes open from 7-8 days, fully open but milky by day 14, feathers open on head day 11, belly and tail day 12, chin and remiges days 14-15, and back day 22, when some grey down still visible; down no longer present by day 31; brooding fairly continuous in first week, becoming irregular by third; average fledging period 42 days in Tanzania and Zimbabwe, 46 days in South Africa, with great variation in interval between 2 fledglings leaving nest (4 hours to 22 days). Double-brooded in parts of range; in Tanzania 3 broods noted, re-laying interval 2-7 days; 2 or perhaps 3 broods in Spain. Success rate 76% in Tanzania and 57% in South Africa; mean annual production 2.5 young, with average 1-1.5 young fledged per breeding effort. Breeding can commence from 2 years of age.

Movements. Migratory in northernmost and southernmost parts of range. Spanish population present early May to Aug-Oct, some recorded into early Dec, with autumn migration through Straits of Gibraltar mid-Aug to mid-Oct; S African population present Aug-May, mainly absent from S Cape and much reduced farther N within S breeding range Jun-Jul. Poorly understood wet-season movements into Sahel may be feature of N sub-Saharan populations. Otherwise resident. Migrates in flocks of up to 100. S African migrants may be transequatorial. Some degree of altitudinal migration in Natal. First record from Arabia 1982, and seen at least once subsequently in Tihamah coastal plains, Saudi Arabia, in Mar 1989. Vagrant to Norway (May, Jun) and Finland (Nov).

Status and Conservation. Not globally threatened. In sub-Saharan Africa localized in wide W African range, increasing in E Africa where commonest swift away from urban areas, and common in S Africa, where population increase primarily result of utilization of bridge construction. Highly localized and scarce in W Palearctic, though increasing in both range and density. Strait of Gibraltar area believed to hold at least 30 breeding pairs, with highest density of 10 pairs in zone with radius of 3 km; Spanish population estimated at 30-100 pairs in early 1990's; breeding confirmed in Portugal in 1995.

Bibliography. Anon. (1996c, 1997a), Ash & Miskell (1998), Aspinwall (1980b), Bannerman (1953), Barlow *et al.* (1997), Barrios (1993, 1994), Beaman & Madge (1998), Benson & Benson (1977), Benson *et al.* (1971), Bernis (1988), Blankert (1980b), Broekhuysen (1971), Brooke (1957, 1964, 1968, 1969a, 1971f, 1971i, 1974b), Brooke & Steyn (1979), Bunning (1987), Carbajo *et al.* (1984), Chantler (1993), Chapman (1969), Cheke & Howe (1990), Cheke & Walsh (1996), Clancey (1971), Cramp (1985), Cumming (1952), Díaz, Asensio & Tellería (1996), Donnelly (1974), Dowsett & Forbes-Watson (1993), Driessens (1994), Earle (1989), Elgood, Fry & Dowsett (1973), Elgood, Heigham *et al.* (1994), Field (1998), Finlayson & Tomlinson (1993), Fry & Elgood (1968), Fry *et al.* (1988), Gatter (1997), Ginn *et al.* (1989), Gore (1990), Grimes (1987), Hagemeijer & Blair (1997), Harrison *et al.* (1997), Hockey *et al.* (1989), Ingram (1972), Johnson & Maclean (1994), del Junco & González (1966, 1969), Lewis & Pomeroy (1989), Lynes & Vincent (1939), Mackworth-Præd & Grant (1957, 1962, 1970), Maclean (1993), Moore (1996, 1998), Moreau (1942b), Ojanen (1983), Pakenham (1979), Penry (1994), Pepler & Martin (1991), Pinto (1983), Porter, Christensen & Schiermacker-Hansen (1996), Rahmani *et al.* (1994), Raw (1981), de Roo & Deheegher (1966), Salvan (1968), Schmidt (1965, 1986), Short *et al.* (1990), Smith (1968), Snow (1978), Snow & Perrins (1998), van Someren (1944), Tree (1973), Zimmerman, D.A. *et al.* (1996).

92. Bates's Swift

Apus batesi

French: Martinet de Bates **German:** Mohrensegler **Spanish:** Vencejo del Camerún
Other common names: Black(!) Bates's Black Swift

Taxonomy. *Cypselus batesi* Sharpe, 1904, Efulen, Cameroon. Monotypic.

Distribution. W Cameroon and N Gabon, Central African Republic, and E Zaire (Kivu Province and Semliki Valley); also Sierra Leone to Nigeria, where status uncertain.

Descriptive notes. 14 cm. Small swift with structure most similar to *A. caffer*, with deeply forked tail; distinctive high-speed flight with rapid flickering wingbeats and occasional short glides. Very black plumage relieved only by typical underwing contrast and indistinctly paler throat-patch. Plumage the most uniform of any *Apus*.

Habitat. Occurs in rainforest zone near rocky extrusions where cliff swallows, especially Dusky Cliff-swallow (*Hirundo fuliginosa*), present. In N Liberia, reported at 500-1500 m.

Food and Feeding. Not known.

Breeding. Breeds Sept-Mar in Gabon, probably Mar and maybe Jan in Liberia, and lays May-Jun in Cameroon. Solitary, nesting in deserted nests of *H. fuliginosa* and probably Lesser Striped Swallows (*H. abyssinica*), which has led to suggestion that other hirundine nests may be used; recorded examining nests of *Telecanthura ussheri*. Lines nest interior and spout with feathers, seed-down and saliva. 2 white eggs.

Movements. Resident.

Status and Conservation. Not globally threatened. Generally rare, but abundance varies and can be locally frequent, with 20-30 birds seen along R Semliki (E Zaire) on three occasions in Oct during late 1930's. Commonest in highlands of Cameroon. Widespread but uncommon in N Liberia.

Bibliography. Bannerman (1931, 1953), Bates (1930), Brooke (1971b, 1971i), Brosset & Éraud (1986), Carroll (1988), Chapin (1939), Christy & Clarke (1994), Colston & Curry-Lindahl (1986), Dowsett (1989a), Dowsett & Dowsett-Lemaire (1993, 1997), Dowsett & Forbes-Watson (1993), Dowsett *et al.* (1999), Dyer *et al.* (1986), Elgood *et al.* (1994), Field (1998), Fry *et al.* (1988), Gatter (1988, 1997), Grimes (1987), Lippens & Wille (1976), Louette (1981), Mackworth-Præd & Grant (1970), Rodewald *et al.* (1994), Rougeot (1951), Serle (1954), Sharpe (1904), Smith & McNiven (1993), Snow (1978), Stuart (1986), Thollay (1985).

Class AVES

Order APODIFORMES

Suborder APODI

Family HEMIPROCNIDAE (TREESWIFTS)

- Small to large branch-perching swifts, partly glossy, with long wingtips that fold scissor-like across deeply forked tail; two species with erectile forehead-crest, others with facial plumes.
- 15-31 cm.

- Oriental Region E to Solomon Is.
- Deciduous savanna woodland to evergreen rainforest.
- 1 genus, 4 species, 13 taxa.
- No species threatened; none extinct since 1600.

Systematics

Obviously glossy above, with rather soft, songbird-like plumage and a branch-perching foot, the "halfway-house" treeswifts helped sustain a long period of confusion over swifts (Apodidae) and swallows (Hirundinidae), groups that taxonomists from Linnaeus to Temminck actually merged and whose relatedness remained controversial until the end of the nineteenth century.

The four currently recognized species of treeswift were all described for science between 1802, when the Grey-rumped Treeswift (*Hemiprocne longipennis*) was named by G. S. Rafinesque, and 1833, when S. R. Tickell separated the Crested Treeswift (*Hemiprocne coronata*). Remarkably, both of these, the first and last to be named, were placed in the old, inclusive genus *Hirundo*, making the Crested Treeswift possibly the last of many species ever to be wrongly classified as a swallow. Whatever his knowledge of the literature of the time, Tickell, then serving in India, would certainly have been the first describer of any treeswift species to have known a member of this family in the field, and so he may be said to have been misled for the very best of reasons.

C. L. Nitzsch's 1829 name of *Hemiprocne* (*hemi progne*, or "half-swallow") pre-dates most evidence for the phylogenetic remoteness of all swifts from swallows, but it validly refers to a treeswift and has priority over two rival family-group names used for these birds. Later, it came to denote more than just the treeswifts as now defined, and not until the 1890's were sound technical reasons put in place for assigning these peculiar birds to a taxonomic position of their own. In 1990, C. G. Sibley and J. E. Ahlquist summarized the history of this research, which had culminated in the recognition of two separate families of swifts. In terms of their anatomy, these two families in fact exhibit more differences from one another than are found among typical families of passerines.

Recognizable as a distinct group at a glance, the four treeswifts include one convincing superspecies that links the Grey-rumped and Crested Treeswifts. These two grey-and-glossy birds have nearly identical vocalizations, and a flap-like forehead-crest 2.5-3 cm tall that both sexes often raise when perched, no doubt as a behavioural signal to mates or others in the home tree. They show a small size difference overall, and differ also in details of face pattern, extent of glossy blackness on the upperparts, one or two minor colour-density features elsewhere, and the proportionate length of the tail-streamers. They were lumped for a time as allopatric representatives of a single species, but their ranges in south-west Thailand are now known to be contiguous, or may ac-

tually overlap, with no evidence of interbreeding. This apparent reproductive isolation is perhaps assisted by the predilection of the two species for mainly different habitats, the Grey-rumped preferring evergreen forest while the Crested selects deciduous growth. This situation is likely to continue west across the dividing range into south Tenasserim, but it has never been investigated there owing to problems over safety of access in that region.

The Whiskered Treeswift (*Hemiprocne comata*) and the Moustached Treeswift (*Hemiprocne mystacea*) are only slightly crested, but they share a bold face pattern. This is characterized by a white supercilium from the base of the bill to the nape, and a malar stripe from the chin along the jaw to the side of the neck, both formed of long hackle-points that trail clear of the head. Otherwise, since the Whiskered is the smallest member of the genus and the Moustached is the largest, these two are less similar to each other than are the two crested species. Moreover, the striped face pattern is actually incipient, though without hackle development, in the female Crested Treeswift, the male of which, however, lacks the malar stripe and shows white only above the lores.

Between them, the three larger species parcel out the family range almost in full. The Crested and the Grey-rumped Treeswifts are distributed parapatrically, their ranges meeting edge to edge in southern mainland South-east Asia, while the Grey-rumped and the Moustached Treeswifts are separated by a short water-gap in the western Moluccas. Only the Whiskered Treeswift occupies a mostly shared range, in which it is substantially smaller than the co-occurring Grey-rumped Treeswift. It differs from all of the larger species in its habitat preference, and operates a unique foraging technique that is presumably related to its small size. It is of interest that in the Philippines, where it is out of contact with the Grey-rumped Treeswift, the Whiskered averages larger in size than in its shared range, raising the suggestion that it may have taken up some vacant niche that would otherwise have been occupied by the Grey-rumped. Rather disappointingly, however, a brief description of the Whiskered Treeswift's foraging behaviour on the Philippine island of Negros gives no hint of the sort of behavioural shift that this species might have been expected to show had this expansion actually occurred.

Morphological Aspects

Technically, the four species of treeswift are distinguished from their relatives, the typical apodid swifts, by details of cranium

Unlike typical swifts, treeswifts are able to perch firmly on twigs and branches with the aid of a non-reversible hind toe.

They sit in rather an upright posture, and normally select a spot which gives them good all-round vision of their immediate surroundings. The Whiskered Treeswift, the smallest of the four species, is also the most active and manoeuvrable in flight, chasing insects and other small flying arthropods in amongst the twigs and leaves, usually staying close to the foliage, and well below the height of the main forest canopy.

shape; the form of the skeletal palate; the anatomy of the tarsus and deep plantar tendons operating the digits; the non-reversible hind toe associated with branch-perching; the lack of a claw on the manus; and the soft, passerine-like feathering, with a patch of downy plumage on the flank. As in typical swifts, the corner of the mouth runs well behind eye-level, to give a broad gape characteristic of an aerial insectivore. The feet and the shallow bill are black to dark purplish-slate, and the eyes are deep brown and proportionately large. The size of the eyes could be a reflection of the fact that foraging activity commonly reaches a peak in the late evening. All post-juvenile plumages are glossy blue- or green-shot black on, at least, the top of the head, the tail, the upperwing-coverts and the flight-feathers, with the tertials, their immediate coverts and the adjacent scapulars mainly whitish, forming a contrasting dorsal patch. Most species also show some white on the central belly or undertail-coverts, darker races of the Moustached Treeswift being the only exception in this respect.

Total length varies from 15-17 cm to 28-31 cm, and wing length from 12-14.5 cm in the Whiskered Treeswift to 19.5-24.5 cm in the Moustached Treeswift. Confining the comparison strictly to swifts, wing length is a reasonable index of wing area, and this combined with body weight can be used to calculate relative wing-loading, which is the amount of lift to be generated per unit wing area. In this case, the Moustached Treeswift, the only one for which reliable body weights have been published, has a lower wing-loading than a large typical swift of the genus *Apus*, and a very much lower one than a similar-sized needletail such as a *Hirundapus* species. This should hold true also for the middle-sized Crested and Grey-rumped Treeswifts, and it does fit with the amount of rather slow gliding and wheeling indulged in by those species while foraging and socializing on the wing. The rather vigorous, bat-like flapping of the little Whiskered Treeswift, on the other hand, is more like that of some small typical swifts in the same environment. On theoretical grounds, this species would not be expected to share the wing-loading advantage of its larger cousins, but this is speculation and the Whiskered Treeswift remains one of the most manoeuvrable fliers of all swifts.

As with typical swifts, most of the length of the treeswift wing is supplied by the primaries, the birds having a long manus but a relatively short arm. The Whiskered, Crested and Grey-rumped Treeswifts moult the primaries in standard swift fashion,

sequentially and descendantly, from the first primary at the carpal joint outwards to the leading edge of the wing. The large Moustached Treeswift, by contrast, regularly moults its primaries from two centres, covering the inner and the outer parts of the tract separately, and sometimes these centres are active together. Apart, perhaps, from reducing the total time taken to replace these feathers, this adaptation may aid in maintaining wing area, since it is unusual at any time to find a bird without a good proportion of its flight-feathers more or less fresh.

All treeswifts also show a remarkably deep forking of the tail. Depending on species, this accounts for 45% to 70% of the standard tail length, far in excess of the figure for any typical swift. Correspondingly long outer streamers, which, as in typical swifts, are narrower and more pointed in adults than in juveniles, give a tail length ranging from about 58% of wing length to, in the Moustached Treeswift, 85% of wing length. With individual variation, and sometimes even a length difference of a centimetre or more bilaterally, this swallow-like feature adds to these birds' manoeuvrability while foraging, an ability taken to extremes by the Whiskered Treeswift, as it works its way around details of the forest canopy "skin". At rest, the tail-points are often tightly adpressed, jutting out spike-like from beneath deeply crossed wingtips to give treeswifts their instantly recognizable shape on a perch.

In all species, the cryptic head and body plumage which characterizes juveniles is lost in a moult that begins soon after fledging, whereas the wing-coverts, flight-feathers and tail are retained until the complete moult of the following year. The juveniles soon lose their pale fringing through wear, and young birds are then aged most easily by the relatively broad, blunt-tipped shape of their tail-streamers (the fifth feather-pair, as in typical swifts).

Habitat

Although regularly occurring along logging tracks, streams and similar places sufficiently broad and open to break the canopy, the Whiskered Treeswift is a genuine member of the continuous-forest community, following vegetation surfaces up around the highest emergent crowns. Only very occasionally does it venture out into tall secondary growth or mature orchards, and even then typically into trees derived from local forest, such as durian. Nevertheless, in various parts of their ranges both the Whiskered and the Moustached Treeswifts have discovered service wires as a substitute for tree perches, but only where these pass through their normal habitat. Nowhere does this new behaviour appear to have expanded the foraging space that these birds exploit.

Among the larger species, the Crested Treeswift is the only one to make extensive use of deciduous forest types, dominated in India, for example, by the tree genera *Anogeissus*, *Boswellia* and *Tectona*. It is not, however, entirely confined to such habitat.

The flight silhouette of the Moustached Treeswift shows the narrow, curved wings and long tail streamers characteristic of the family. This relatively common species is found in parkland and partly cleared forest, and also in more "natural" habitats such as forest margins, mangroves and riverside woodland. It often hunts above the tree tops or over open country, and its typical flight behaviour involves much gliding.

This Whiskered Treeswift illustrates several of the typical features of the genus *Hemiprocne*. The bill is very short, but the mouth extends well back to just below the eye. The bristles surrounding the mouth may help the birds to gather up insects as they fly. The dark brown eye is relatively large, a feature which allows for good vision, even when foraging around dawn and dusk, when light levels are low. The striking white lines above and below the eye contrast markedly with the rest of the plumage. Males, like this bird, have chestnut ear-coverts, whereas in females they are green.

as it also reaches perhumid parts of Sri Lanka and similar places elsewhere. The Grey-rumped Treeswift demonstrates the ecological breadth virtually of the whole family in the range of vegetation types occupied, from mature mangroves to evergreen hill forest at 1000-2000 m. All the larger species, nevertheless, very definitely prefer edge habitat, sallying partly over continuous canopy but just as often over open ground, and seemingly dependent on the interface between high canopy and gaps for their home sites. The Crested and Grey-rumped Treeswifts, and probably also the Moustached, reach some of their highest local population densities in mature parkland, forest fragmented by agriculture and, in the case of the Crested Treeswift, groves or gallery woodland actually in savanna country. All three also show a clear preference for perching in bare and exposed parts of the upper crown, from which they have an uninterrupted view of local airspace and, no doubt, of the foraging activity of neighbours. The Whiskered Treeswift also chooses exposed look-outs and nest-sites, but in edge situations typically much further down the vegetation profile, and, unlike the other three, it never hunts over open ground.

General Habits

The treeswifts exhibit bio-mechanical features of both the typical swifts and the swallows, and sharing some of the foraging advantages of these divergent groups imposes a social order that is intermediate between the two, but rather more swallow-like than swift-like. Whereas by breeding and foraging communally most of the typical swifts encountered by treeswifts seem to be trading scarcity of nesting sites for information-exchange on food location, no treeswift has this fitness opportunity at the nest.

The forest-living Whiskered Treeswift is, if anything, more swallow-like than most swallows! Strictly dispersed throughout the year, the pair plus not more than one offspring find food exclusively around a small, apparently unshared activity space. How they defend this space is unknown, and the greater premium may just be on mutual avoidance. A juvenile monitored in Selangor, Malaysia, left the parental territory within weeks of fledging.

None of this species' three larger relatives, all of which inhabit forest edge rather than the interior forest, has been well studied away from the nest, but all seem to have gained something of the best of both worlds. Nesting in the open, they are dispersed breeders like the Whiskered Treeswift. Unlike that species, though, neighbours consort when hunting, apparently regardless of the stage of the breeding cycle. Should only two or three pairs meet, each could still gain a foraging advantage from the communal searching of some collective space for what could be patchy food even for a dietary generalist. It is worth noting here that the extent to which any treeswift specializes in the food it takes has yet to be determined.

As breeding for the year draws to a close, so sociality among the larger species increases. The age-groups participating are unknown, but stable parties can assemble alongside breeders. Thus, a noisy pack of Grey-rumped Treeswifts, presumably including parents, is on record as accompanying the first flights of a late fledgling. Parties of this species also mob Asian falconets (*Microhierax*), which, to judge from their regular hunting behaviour, are liable to be predators of nestling treeswifts.

Outside the breeding season, the three larger species tend to shift ground. How far this applies to established pairs is unknown, but reports of the periodic abandonment of nesting areas apply to all. Rather little is known about this aspect of the Crested Treeswift's biology. Non-breeding Grey-rumped Treeswifts, however, regularly gather in parties of up to 50 birds and occupy a communal home tree at the edge of forest or in semi-open country, including casuarinas at the shore, for several winter months at a stretch, returning to the same tree season after season. No directly comparable behaviour has been recorded for the Moustached Treeswift, but mobility and communal foraging are a normal part of the life of this largest species too. An astonishing 2000 or so individuals reported over a highland valley in western Papua New Guinea would be in line with some fairly spectacular socializing.

Voice

The two crested species, in particular, have a limited repertoire of rather powerful, hysterical-sounding squeals, given freely in

The Crested Treeswift is notable for a distinctive forward-pointing crest, which is often raised, especially as a signal when other birds are perched close by. This species may most easily be distinguished from the very similar and closely related Grey-rumped Treeswift (*Hemiprocne longipennis*) by the fact that its tail streamers project well beyond the tips of the folded wings.

[*Hemiprocne coronata*,

Ardea]

social contexts: while wheeling and soaring; accompanying a newly flying youngster; or mobbing a predator. Arriving foragers are similarly greeted by a waiting mate or, as non-breeders, by a ragged chorus of neighbours around the home perch.

The vocalizations of the Crested and the Grey-rumped Treeswift are more or less identical. They include a screaming "kee" or "kia", given singly or in a series; a disyllabic call, the main flight-call, variously rendered as "ti-chuk", "whit-chuk", "kee-kik" or "chwe-chwep"; and, commonly in a greeting chorus, a trisyllabic "kip-KEE-kep" or "ki-KEE-kik", stressed heavily on the middle note. The calls of the Moustached Treeswift, also given socially, including in flight, are a high-pitched, downslurred squeak or squeal, "kiiee" or "whiiee"; a softer, upslurred whistle, "owi-wi-wi-wi"; and a loud flight-call, "wick", likened to the call of a sparrowhawk (*Accipiter*).

Whiskered Treeswifts are generally quieter than their larger, more social relatives, and their calls are less well described. Communications between pair-members, perched and in flight, include a high-pitched "chew" or "kweeo" and peal of shorter notes, "kwee kwee, kwi-kwi-kwi-kwi", as well as a "she-she-she-SHEW-she". In this last series, the stressed syllable is pitched higher, as is the case with the crested species.

Food and Feeding

Although arthropods appear to constitute the diet, very little is known of what specific prey treeswifts do actually catch. There is no information at all for the Whiskered Treeswift; a mention only of termites and bees for the Grey-rumped; records of bugs, beetles and small flies for the Crested; and reports of bugs, beetles, bees and ants for the Moustached. No quantitative data are available on the diet of any species. Furthermore, how treeswifts and "true" swifts cope with bee venom is not understood, and the Moustached Treeswift is also reported to take bugs of the family Pentatomidae, another group of insects equipped with good chemical defence.

Among the typical swifts, the known dietary specialists are all medium-sized to relatively big, fast-flying birds covering large distances per foraging day. By contrast, the treeswifts, being tied socially to the crown of a home tree, of necessity exploit a relatively limited and more or less fixed amount of airspace daily, and over long periods. On theoretical grounds, they have a need to hunt opportunistically, taking a good range of whatever comes by that is within handable and energy-efficient prey-size limits. Flexibility of flight mode, from virtually swallow-like manoeuvring up to the fast-forward pace of a big typical swift, pre-adapts the larger species to such a diet, obtained at foraging heights commonly shared with several individually less versatile species of swallow and typical swift. In comparison, the small for-

aging space (often not more than two or three large tree crowns) utilized by a pair of Whiskered Treeswifts specialized in delicate manoeuvring is shared extensively with only one other, still smaller, aerial insectivore, the Glossy Swiftlet (*Collocalia esculenta*).

Typically, prey are taken on the wing, although it seems likely that close in to canopy surfaces the Whiskered Treeswift picks off the occasional food item perched or hanging from the tips of exposed foliage, as also do small apodid swiftlets in these situations. The larger species, at least, forage more intensively in the early mornings and late evenings than at other times, and the Moustached Treeswift is recorded as making the occasional sally even after dark. All treeswifts also tend to be active after rain.

Breeding

No specific sexual display flight has been described for any species of treeswift, although noisy soaring by the larger species is likely to have some social meaning, as yet uninvestigated. An instance of in-flight copulation by the Grey-rumped Treeswift is on record from Sulawesi: the male on top, with wings fully extended, and the partners holding together for about 3 seconds, calling loudly throughout. On the other hand, at least two independent descriptions exist of Moustached Treeswifts copulating on a perch.

The overall breeding seasons of all the species are long. Where adequate information is available, they show a peak of activity in spring or early summer, or twin peaks. There tends to be a break only from late autumn to the beginning or middle of winter, timed according to hemisphere and probably with local variations.

As with the typical swifts, both pair-members co-operate in nest building. They develop the rim of the nest with strands of saliva into which they embed thin flakes of bark, body feathers and small fragments of bryophyte before the solution hardens. The body feathers used are probably mostly, but not exclusively, their own. The Whiskered Treeswift has been shown to add saliva and feathers after laying, and actually while incubating, but the final shallow structure appears only just large enough to contain the single egg, standing proud of the rim like a rather large acorn in its cup.

The nest varies in size according to species, but is only 25-40 mm across at its longest diameter. It sits atop or, more often, forms a hemispherical bracket off the side of a typically narrow, bare twig. Invariably, this twig, often pencil-thin, is fully exposed at the edge of the canopy, giving uninterrupted flight access in most directions. The thinness of the support must help with perching, but may also aid in detecting the approach of a climbing predator. Snakes are active mainly at night, and sleeping on long, thin wands is one of the regular anti-snake strategies adopted by small birds of many kinds which roost in tropical forest.

The Grey-rumped Treeswift shows certain differences from the Crested Treeswift in terms of habitat preference: while the former inhabits evergreen forest, the latter tends to be found more often in deciduous trees. As its vernacular name suggests, the Grey-rumped Treeswift has a noticeably pale greyish rump. Both tend to be found at the edges of forest, and they may have benefited in some areas from disturbance to the denser original forest.

By day, an empty and unattended nest, seen from a distance, passes for a small, natural woody excrescence, but the plain white egg, often as broad as or even broader than the supporting twig, is by no means cryptic. Treeswift eggs are not well represented in museum collections; indeed, comparative data have been obtained on only two of the four species, the Crested and the Grey-rumped Treeswifts. The shape of these eggs varies from rather broad to a distinctly long, regular oval; the colour from plain white, as also given in all field accounts of the Whiskered Treeswift egg, to the palest shade of grey; and the surface texture from matt to occasionally very slightly glossy. Twelve eggs of the Crested Treeswift measured roughly 23-26 x 15.5-19 mm, while a smaller sample of six Grey-rumped Treeswift eggs measured 23-24.5 x 17-18 mm; the approximate measurements of single Whiskered and Moustached Treeswift eggs were 20 x 15 mm and 30 x 20 mm respectively.

The egg of the Crested Treeswift is said to be gummed to the nest, and it is hard to see how any treeswift egg could survive long on a twig swayed by breeze were it not fixed down. Whether this securing of the egg is by a deliberate act of the parent or is incidental to the moistening and drying of the nest "cement" has not been established.

The orientation of the incubating or brooding adult varies according to the position of the nest on its support, and the latter's thickness. Typical brackets on thin twigs are completely tented by the parent's lower-breast and belly feathering as it perches crosswise on the support, facing and straddling the nest, and a bird incubating in this position cannot be distinguished from one merely resting. A Whiskered Treeswift pair has been seen to leave an egg unattended for several minutes, but a typical incubation relief schedule, recorded in this and the Crested Treeswift, exposes the egg only momentarily. Field observations on nests of these two species reveal that the share of incubation duties taken by females is two or three times greater than that of their mates.

No exact measurements have been made of the incubation and fledging periods, but a Malaysian egg of the Whiskered Treeswift hatched on or before day 21 and the chick flew soon after its 28th day, being fed by both parents at least occasionally for a minimum of three more weeks. At the opposite end of the size spectrum, incubation and fledging of the Moustached Treeswift together occupy more than 60 days.

As with typical swifts, the young treeswift chick is fed a bolus of food, regurgitated from the parent's throat into its open mouth. Later, it takes this food direct from the parent's mouth. A Whiskered Treeswift chick was fed from its first day of life, and within a short time of hatching.

On hatching, the chicks have grey skin and sparse grey down, although descriptions of young Grey-rumped and Moustached Treeswifts suggest that, when dry, they may be fairly well covered. Two or more weeks before flight, the developing chick outgrows the nest, and about the time when its first contour feathers begin to erupt it transfers to the nest support. In all four species this juvenile plumage is cryptic, and remarkably different from that of the adult. In-the-hand descriptions exist for all except the Whiskered Treeswift. The wings, their coverts and the tail are sooty-black, boldly fringed and tipped white to rufous-cream, according to species; the cap and upper body are black, broadly fringed white, cream-buff or, commonly in the Moustached Treeswift, rufous, in addition to which the cap feathering is subapically zoned buff, dark brown and/or rufous. Non-black zones take over to give a pale forehead and lateral coronal bands in the Crested Treeswift, and in the stripe-faced species an incipient supercilium and malar streak are evident. The tertial patch, white in adults, shows buff, typically with a subapical band of dark brown. The underpart feathers are pink-buff with an outer zone of dark brown and a white fringe; or, in the Moustached Treeswift, like the upperparts down to the breast, then buff with bands of black, rufous and white. The colours and the entire coarse, mealy pattern simulate lichen-covered bark, this effect enhanced by the behaviour of the chick when unattended: sitting rigidly upright with head tipped to align the bill, and with the otherwise contrastingly dark eye closed, it passes off easily as a small branch stub.

Movements

No treeswift migrates in the regular sense, and the forest-living Whiskered Treeswift is strictly sedentary, remaining in its nesting territory all year round. Seemingly erratic comings and goings imply that the Moustached Treeswift may be nomadic in parts of its range, but the scope of individual journeys may not be more than local. While there is the contrary indication of a

The Whiskered Treeswift is small and light, and well able to perch even at the tips of thin twigs, as it waits between feeding forays. Treeswifts also roost in such situations, which probably offer them an extra degree of safety from non-flying predators, such as snakes. Of all the treeswifts, this species is tied most closely to natural forests, and it is seen much less often in parks, orchards or plantations. Unlike the other treeswifts, it prefers to perch and hunt in amongst the branches and twigs of the forest trees, rather than venturing into the open skies above the forest canopy.

comata,
Sabah, Borneo.
Photo: Sarah Whitley]

Treeswifts build tiny nests from feathers, bark and leaf fragments, glued together and onto the top of a branch using saliva. The nest is often hard to spot, as it may be situated high in a tree, and looks like part of a branch. The nest is rather fragile, with thin, papery walls, and is only just big enough to hold the single egg. It is unable to support the adult, or even a large chick; indeed, this Moustached Treeswift chick has outgrown its nest. The adult incubates the egg by squatting on the branch, at which time it completely hides the nest from view with its body. Clearly visible here are the scythe-shaped wings, which cross over when the bird is at rest, and the streamers of the deeply forked tail.

casualty recovered from the permanent snow zone of the Carstensz Mountains in Irian Jaya, a good 3000 m above terrain regularly used by the species, this one-off record is backed by no other evidence.

Both the Crested and the Grey-rumped Treeswifts shift seasonally, possibly only locally, although the size of some winter gatherings of the latter species in the Malay Peninsula leads one to conclude that these may draw recruits from a fairly wide range. It has not yet been shown whether such gatherings include full adults, although year-to-year usage of favoured trees implies that they probably do.

Relationship with Man

Rather surprisingly for noisy, visible birds which often live on the outskirts of villages, there appears to be very little information on the attitudes of humans towards treeswifts in their native countries. Indeed, no cultural or economic links are known between these birds and local human populations. It is tempting to suggest that treeswifts are "welcomed" because they are clearly insectivores, consuming rather large quantities of insects which might be considered potentially injurious pests, but there is no definite evidence that this is the case. Whatever the motivations, it appears that treeswifts and man generally co-exist, with limited direct contact and no regular conflict.

Given access to high perches and nest-sites, treeswifts, including the forest-dwelling Whiskered Treeswift, are not put off by regular human traffic nearby, appearing to rely completely on the security provided by their resting perches and nests from terrestrial predators. That treeswifts have little fear of man is nicely illustrated by the following account. In 1939, the eminent ornithologist E. H. N. Lowther described the boldly confiding behaviour of a pair of Crested Treeswifts near Dhanbad, in Bihar, east India. The two birds continued their nesting duties as normal while he photographed them from a hastily built platform, in full view and at no more than arm's length from the nest. On only the second day of his observations, the female allowed him to ruffle her feathers, and grappled with an offered finger as she incubated. In order to see the contents of the nest, Lowther had actually to push the sitting adults off it.

Status and Conservation

While hunting partly over the canopy of continuous forest, most treeswift species select home trees to which they return between sorties. These trees are situated where forest meets open space. Over much of the family range, windthrow clearings and river courses would have been almost the only available edge habitat, until conditions were vastly extended along expanding systems of roads and around settlements and agriculture. Forest-bound Whiskered Treeswifts respond to space opened up along log-extraction tracks and other small roads, while all the larger species have actively spread into cultivated landscapes, including even the planted timber of gardens and parks. Some of the densest local populations of, for example, the Grey-rumped Treeswift are actually in these latter types of situation.

No treeswift species could survive total clearance of tall trees, and none occurs in oil palm monoculture, the crop now most extensively replacing forest throughout the humid lowlands of the family range. All, however, appear likely to have benefited from the intermediate fragmentation of continuous forest cover. Over their entire range, at present, all treeswifts are regarded as common birds, although the Whiskered Treeswift is as vulnerable to outright habitat loss as is the rest of its community: not yet under direct threat, but a species to be watched.

The collapse of the Grey-rumped Treeswift population in Singapore, as measured by a decline in the size of non-breeder gatherings, has no immediately obvious connection with availability or quality of habitat there. The unusual scarcity of certain other typical swift species there compared with the nearby mainland points more directly towards a problem with aerial plankton and, ultimately, pesticides. In western Indonesia, most seriously Java, random hunting of all birds has become a problem for the conservation of non-forest populations of the Grey-rumped Treeswift.

PLATE 44

Family HEMIPROCNIIDAE (TREESWIFTS)
SPECIES ACCOUNTS

Genus *HEMIPROCNE* Nitzsch, 1829

1. Crested Treeswift
Hemiprocne coronata

French: Hémiprocne couronné

Spanish: Vencejo Arborícola Coronado

German: Kronenbaumsegler

Other common names: (Indian) Crested Swift

Taxonomy. *Hirundo Coronata* Tickell, 1833, Borabhum and Dhalbhum, Bihar-Bengal border, north-east India.

Forms a superspecies with *H. longipennis*, with which it has been considered conspecific: morphological differences are constant, however, with no evidence of intergradation where parapatric ranges of the two meet. Monotypic.

Distribution. Sri Lanka, India (W to N Uttar Pradesh and SE Gujarat), S Nepal and S Bhutan to Myanmar, SC China (SW Yunnan), NC & W Thailand (S to Kaeng Krachan) and S Indochina.

Descriptive notes. 23-25 cm. Adult has crest dark greenish-blue, 2.5-3 cm tall. Male uniformly pale greenish-grey from central crown to uppertail-coverts; lores black, finely bordered white above; anterior ear-coverts, lower face, chin and variable extent of throat rufous; wing-coverts glossy greenish-black; underwing-coverts pale grey, concolorous with breast and flanks, and belly and undertail-coverts whitish. Differs from *H. longipennis* in tail-streamers projecting well past folded wing-tips. Female lacks rufous on face, has grey-black ear-coverts and cheeks, white moustachial stripe and grey chin and throat. Juvenile a finely banded mixture of sooty-black, rufous, buff and white, predominantly dark above, with pale forehead and lateral coronal band, and white spot in front of eye.

Habitat. Scattered trees, groves, and edge and canopy breaks of more or less continuous, fully to mainly deciduous forest (dry dipterocarp, teak, etc.); also tall secondary growth and, marginally at

Indian Subcontinent, becoming bimodal (Mar-May and Jul-Sept) in Sri Lanka, and recorded Mar-Jun in Myanmar. Nesting dispersed, but several pairs may occur in the same general area. Nest a half-saucer of hardened saliva incorporating small, sometimes overlapping flakes of bark and body feathers, c. 12 mm thick and built as a bracket 20-30 mm wide, 4-18 m up on a live, usually thin branch in open canopy. Lays 1 egg, which is glued to the nest; incubation by both sexes, period unrecorded; nestling down grey; chick is brooded more or less continuously through the down-plumage stage, and fed by both parents; fledging period unrecorded, but appears to be longer than 4 weeks.

Movements. Mainly resident; seasonal dispersive movements are perhaps only local; records from Bangladesh may refer to vagrants or to rare resident population.

Status and Conservation. Not globally threatened. Patchily distributed and often local, but relatively common, and able to live close to human activity; rare in Bhutan, Bangladesh and NE India. Selection of edge habitat and capacity to use tall secondary growth suggest that it may have benefited from moderate forest disturbance. Under serious threat only in those areas where clearance has reached the point of severe tree loss.

Bibliography. Ali (1996), Ali & Ripley (1983), Bangs & Van Tyne (1931), Brooke (1969e), David-Beaulieu (1949-1950), Deignan (1945), Delacour & Jabouille (1940), Duckworth (1996), Engelbach (1932), Étchécopar & Hue (1978), Grimmett *et al.* (1998), Harvey (1990), Henry (1998), Inskipp, C. & Inskipp (1991, 1993), Inskipp, T. *et al.* (1996), Legge (1983), Lekagul & Round (1991), Lowther (1936), Meyer de Schauensee (1984), Osmaston (1921b), Phillips (1978), Riley (1938), Robertson (1993a), Robson *et al.* (1989), Round (1988), Smythies (1953, 1986), Stanford & Smith (1936), Sugathan & Varghese (1996), Thewlis *et al.* (1996), Thompson *et al.* (1993), Whistler (1930).

2. Grey-rumped Treeswift

Hemiprocne longipennis

French: Hémirocné longipenne

Spanish: Vencejo Arborícola Culigrís

German: Haubenbaumsegler

Other common names: Crested Treeswift(!)

Taxonomy. *Hirundo longipennis* Rafinesque, 1802, Java.

Forms a superspecies with *H. coronata*, with which formerly sometimes treated as conspecific. Several races have been described, but most nowadays considered invalid, e.g. *ocyptera* (Nias I), *thoa* (Batu Is, Pagi Is, Enggano I) and *anochra* (Natuna Is). Four subspecies recognized.

Subspecies and Distribution.

H. l. harterti Stresemann, 1913 - S Myanmar (S Tenasserim) and SW Thailand S & E to Sumatra, Borneo and intervening islands, and Sulu Archipelago E to Tawitawi (Philippines).

H. l. perlonga (Richmond, 1903) - W Sumatran islands from Simeulue to Enggano.

H. l. longipennis (Rafinesque, 1802) - Sunda Strait (Panaitan I) through Java to Lombok, and Kangean Is (E Java Sea).

H. l. wallacii (Gould, 1859) - Sulawesi, including S and E satellites, and Sula group (W Moluccas).

but dorsal patterning often more complex, particularly on cap, which lacks contrasting lateral band, and has no obvious pale loreal spot. Races *harterti* and *perlonga* shade darker than nominate on anterior underparts, and rump less pale in relatively large *perlonga*; *wallacii* largest, with plumage much as nominate.

Habitat. Groves of large trees and edge and canopy breaks of more continuous semi-evergreen and evergreen forest inland, locally tall mangroves and coastal casuarinas, also making use of tall plantation and mature parkland trees. Everywhere selects well-exposed, bare perches at outer edge of the high canopy. From plains level to 1200 m in Malay Peninsula, to 1550 m in Java.

Food and Feeding. Flying arthropods; prey selection hardly known, but regularly attends swarms of alate termites and, in Borneo, recorded taking bees from the edge of a flying swarm. Prey caught during long sorties out from a favoured tree crown, typically well clear of vegetation surfaces. In Selangor, Malaysia, mean foraging height above open ground was 35 m, and above forest canopy was 47 m. Like other Apodiformes, drinks by scooping water in a fast, skimming swoop down to an open surface.

Breeding. In N Hemisphere, laying season overall Feb-Aug/Sept (chick records in Oct), peaking in Mar-Jun; in S (Java) active nests Dec-Aug. Nesting dispersed but, as with *H. coronata*, often with several other pairs in the neighbourhood. Nest as that of *H. coronata*, built by both sexes, typically a half-saucer of hardened saliva incorporating small scraps of moss, bark flakes and body feathers, c. 36 x 24 mm, maximum outside depth 12 mm, built out as a bracket 5-30 m up on a thin, exposed branch. Lays 1 egg; both pair-members incubate and both tend the chick; incubation and fledging periods not recorded; chick down is grey.

Movements. Breeds over its whole altitudinal range, with probably no more than post-breeding local dispersive movements.

upper limit of range, semi-evergreen forest. Selects bare, exposed perches on outer surface of the canopy. From plains level to about 1300 m in Indian Subcontinent, to 1400 m in SE Asia.

Food and Feeding. Flying arthropods; diet said to include hemipteran bugs, beetles and small flies, but hardly analysed and proper details are lacking. Captures prey during long sorties out from high perches into free space clear of vegetation surfaces, including well above the forest canopy.

Breeding. Season Dec-Oct overall, with regional variation: peak activity Jan-Apr in

Status and Conservation. Not globally threatened. More or less common through most of its range, and under no serious threat overall. As with *H. coronata*, preference for patchy tree cover and edge habitat over continuous natural forest suggests that it may in fact have benefited from some forest disturbance; the species is absent, however, from still rapidly expanding oil palm agriculture, and populations in the plantation landscape would benefit from a commitment to the maintaining of natural or semi-natural shelterbelts. The opposite trend is set in Malaysia, where over-use of organophosphate pesticide sprays in suburban parkland habitat is another rising issue. Pesticides are suspected to be behind a recent population decline in Singapore. Elsewhere, the general impression is that bird-hunting, exacerbated by expanding availability of airguns, will have damaged non-forest populations through much of W Indonesia; hunting has caused quite severe reduction of nominate race, along with nearly all bird species, in lowland Java.

Bibliography. Allen (1952), Bishop (1992), Bromley (1948), Brooke (1969e), Brooks & Dutton (1997), Bucknill & Chasen (1990), Coates & Bishop (1997), Coomans de Ruiter (1935), Dickinson *et al.* (1991), Duckworth & Kelsh (1988), Duckworth *et al.* (1997), Dymond (1994), Eck (1976), Gibson-Hill (1950b), Glenister (1951), Hails & Jarvis (1987), Hellebrekers & Hoogerwerf (1967), Holmes, D.A. (1994a), Holmes, D.A. & Burton (1987), Holmes, D.A. & Philipps (1996), Hoogerwerf (1965), Inskipp *et al.* (1996), Johnstone *et al.* (1993), Lekagul & Round (1991), MacKinnon (1988), MacKinnon & Philipps (1993), Madoc (1976), van Marle & Voous (1988), Medway & Wells (1976), Mees (1986), Nash & Nash (1988), duPont & Rabor (1973a), Riley (1938), Robertson (1993a), Round (1988), Smythies (1981, 1986), Somadikarta (1975b), Stones, Lucking *et al.* (1997), Vowles & Vowles (1984), Wardill (1995), Watling (1983), Wells (1999), White & Bruce (1986), Wilkinson *et al.* (1991).

3. Whiskered Treeswift

Hemiprocne comata

French: Hémirocné coiffé

German: Ohrenbaumsegler

Spanish: Vencejo Arborícola Chico

Other common names: Lesser Treeswift

Taxonomy. *Cypselus comatus* Temminck, 1824, Sumatra.

Additional races proposed for some of islands off W Sumatra (*stresemanni*) and for some of Philippines (*nakamurai*), but both now considered invalid. Two subspecies currently recognized.

Subspecies and Distribution.

H. c. comata (Temminck, 1824) - S Myanmar (S Tenasserim) and peninsular Thailand S to Sumatra (including W Sumatran islands) and Borneo and intervening islands.

H. c. major (Hartert, 1895) - Philippines, including Sulu Archipelago, but excluding Palawan.

Descriptive notes. 15-17 cm. Only slightly crested. Male mostly dark bronze, with bold supercilium from forehead and lores to hind-nape and a more or less parallel stripe from chin back to side of neck, both sharply white against otherwise glossy black head and throat; lower ear-coverts dark chestnut. Female similar, but ear-coverts deep blue-green. Juvenile finely barred brown, tawny, grey and white, much as congeners; whitish facial stripes shorter than in adult. Race *major* has more white on abdomen and tertials, broader, blunter, more juvenile-like tail-streamers, and proportionately shallower tail-fork; also averages

larger, but Sumatran and Malay Peninsula birds both increase in size clinally northwards, giving much overlap between races.

Habitat. Small cover breaks and the main canopy of evergreen forest inland, and locally also of tall, mature mangroves. From plains level up to 1000-1100 m on major slopes, but not above 800 m in N Malay Peninsula.

Food and Feeding. Small flying arthropods, but diet not analysed. Compared with typical behaviour of co-occurring *H. longipennis*, forages from perches further down the canopy profile, taking prey in much shorter sorties close to vegetation surface; never above main canopy height.

Breeding. Over most of range lays Feb-Aug (latest fledglings in early Oct); the few Philippine records, dated only May. Nesting dispersed and breeding pairs territorial. Nest a half-saucer of hardened saliva incorporating feathers, but no published confirmation of vegetable matter included; built 8-40 m up as a bracket or on upper surface of a thin, exposed branch; construction continues after laying. Lays 1 egg; both pair-members incubate and tend the chick; natal down colour not described; in one instance, an egg hatched on or before day 21 and the chick flew soon after day 28, giving total development time of probably not less than 50 days.

Movements. Sedentary; breeding pairs are believed to remain in their nesting territory throughout the year.

Status and Conservation. Not globally threatened. Reported as common in most parts of range; very few recent records from Singapore. Tied more exclusively to original forest, hence at greater risk of outright habitat loss, than others of genus. Exceptional in secondary growth, but able to exploit edge created by selective logging.

Bibliography. 4. Moustached Treeswift

Hemiprocne mystacea

French: Hémirocné à moustaches

Spanish: Vencejo Arborícola Bigotudo

German: Bartbaumsegler

Other common names: Whiskered Treeswift(!)

Taxonomy. *Cypselus mystaceus* Lesson, 1827, Dorey, Vogelkop, Irian Jaya.

Six subspecies recognized.

Subspecies and Distribution.

H. m. confirmata Stresemann, 1914 - Moluccas (excluding Kai and Sula groups) to Aru Is.

H. m. mystacea (Lesson, 1827) - New Guinea mainland; islands of Geelvink Bay and W Papuan Is.

H. m. aeroplanes Stresemann, 1921 - Bismarck Archipelago (excluding Admiralty Is and Feni Is).

H. m. macrura Salomonsen, 1983 - Admiralty Is.

H. m. woodfordiana (Hartert, 1896) - Feni Is and most of Solomon Is (including Bougainville).

H. m. carbonaria Salomonsen, 1983 - Bauro I (Solomons).

Descriptive notes. 28-31 cm; 56-79 g. Only slightly crested. Male has two bold white facial stripes contrasting with glossy black cap and black face, with lower ear-coverts variably dark chestnut; rest of body blue-grey, paler below, with usually white central belly to undertail-coverts. Female differs only in having dark blackish-green ear-coverts. Juvenile head and body feathers complexly zoned black, rufous, buff and white, generally black-based dorsally and anteriorly, with cream-rufous forehead, lateral coronal bands and malar stripes, and with rear underparts cream-based. Races differ mainly in size and in body colour:

all others smaller than mainland nominate, *confirmata* otherwise similar; *aeroplanes* and *macrura* have less white on vent, latter also particularly long-tailed; *woodfordiana* and *carbonaria* smallest and with uniformly dark body.

Habitat. High emergent crowns in mangroves and beach-strand woodland, scattered trees and groves, and edge of inland forest (gallery forest in savanna areas) overlooking open country and along rivers that broadly break the canopy. From sea-level to 1580 m; a casualty recovered from ice at 4400 m in the Carstensz range.

Food and Feeding. Takes flying arthropods, including bees, ants, hemipteran bugs and beetles, in length range 6-18 mm. As is typical of the family, forages from bare, exposed perches at the top or

outer edge of canopy; launches often-long sorties into free airspace, including well above the canopy, returning each time to the favoured crown

Breeding. Active nests recorded in all months except Mar; season locally variable, can be long. Nesting is dispersed, and pairs believed to be territorial, at least around the nest-site. Nest a tiny saucer of feathers and plant material incorporated in hardened saliva, fixed on the top of a high, horizontal branch (no bracket nest described); simulates a small knot and, as with congeners, is completely hidden by the sitting adult. Lays 1 egg; both sexes incubate, but most brooding of the young chick is by female; combined incubation and fledging period in excess of 60 days. A record of possible second brood, at same nest, in Port Moresby area.

Movements. Locally dispersive resident, but perhaps nomadic in some areas; movements little studied.

Status and Conservation. Not globally threatened. Relatively common generally, with no hint yet that any race is threatened, although some individual Wallacean island populations may be under pressure. The mainland New Guinea range still carries an immense extent of suitable habitat, and the species' capacity to use broken landscape suggests that, except possibly in some W islands, it can withstand much more damage to forest than has occurred to date. On the other hand, no information exists on how it responds to plantation agriculture, which is the future of the lowlands of the region. In Irian Jaya widespread settlement of W Indonesian transmigrants will greatly increase the level of bird-hunting, a traditional activity of these people.

Class AVES
Order APODIFORMES
Suborder TROCHILI
Family TROCHILIDAE (HUMMINGBIRDS)

- Small to tiny fast-flying birds, with extensively iridescent plumage, many with strikingly coloured gorget or crest; thin bill extremely variable, from short to extremely long, from straight to sharply curved; feet tiny.
- 5-22 cm (with tail streamers, up to c. 35 cm).

- New World, mainly Neotropical.
- Wide variety of habitats, wherever suitable food plants occur, from sea-level up to c. 5000 m, with greatest diversity in submontane zone.
- 102 genera, 328 species, 684 taxa.
- 25 species threatened; 1 definitely extinct since 1600.

Systematics

Hummingbirds (Trochilidae), with some 328 recognized species, are one of the largest avian families in the New World, surpassed in species number only by the tyrant-flycatchers (Tyrannidae) with over 370. Although hummingbirds form an undisputed phylogenetic unit, their sister-group relationship is still debated. Traditionally trochilids are placed within the Apodiformes, together with the treeswifts (Hemiprocnidae) and the true swifts (Apodidae). This classification is based mainly on anatomical and morphological characters, such as modified cervical musculature, the skeleton of the flight apparatus, wing muscle innervation, or feather tracts, and the question still remains whether these similarities are due to convergence or to common ancestry. This debate has led some classifiers to place hummingbirds in an order of their own, Trochiliformes.

Recent biochemical studies favour the traditional classification: swifts and hummingbirds share a unique form of the enzyme malate dehydrogenase. This phylogenetic treatment is corroborated by the DNA comparisons of C. G. Sibley and J. E. Ahlquist.

Today, the monophyly of swifts and hummingbirds is widely accepted among ornithologists. The divergence is probably ancient and may date back to the beginning of the Tertiary (c. 65 million years ago) or even to the late Cretaceous (c. 70 million years ago), when a large tectonic plate broke from Gondwanaland, giving rise to South America. The relationship of the apodiforms to other avian groups is the subject of rather controversial debate. Affinities to nightjars and their allies (Caprimulgiformes) based on patterns of feather growth (pterylosis), to mousebirds (Coliiformes) from intestinal tract comparisons, and even to the "pico-passerine assemblage" of the songbirds (Passeriformes), derived from feather structure and egg-white protein analysis, have been suggested by various systematists. Most of the evidence for these links is based on similarities of debatable significance, and not on a common possession of derived characters (synapomorphies) defining monophyletic lineages. Modern anatomical methods, careful morphological character analyses, and molecular biology techniques may in the future shed some light on these unsolved problems of higher-level relationships.

Several attempts to classify hummingbird genera and species have been made since the second half of the 19th century, and indeed most of our present knowledge of systematic affinities within the family dates back to that time. When J. L. Peters

published Volume 5 of the *Check-List of Birds of the World* in 1945, dealing with the Trochilidae, he basically followed E. Simon's classification of the family formulated in 1921. Except for some minor modifications this list is still in use today.

Subdivision of the Trochilidae
(Figure: Hilary Burn)

The hummingbirds are traditionally situated alongside the swifts (Apodidae) and tree-swifts (Hemiprocnidae) in the Apodiformes.

This placement is based on skeletal and muscular similarities, supported by analyses of proteins and genetic material.

The relationship of the Apodiformes to other orders is more obscure, but they have been linked with nightjars and allies (Caprimulgiformes), mousebirds (Coliiformes) and passerines. Within the family, provisional taxonomic adjustments are a constant feature.

The Purple-throated Woodstar, for example, was previously placed in the genus *Philodice* but this has recently been subsumed into the genus *Calliphlox*.

Modern phylogenetic studies of hummingbirds have mainly focused on species- and genus-specific questions. Surprisingly little is known about the general relationships within the Trochilidae. There are two major reasons for this: first, the lack of fossil hummingbird records except for a few modern species, mainly from West Indian Quaternary cave deposits; second, most previous classificatory studies concentrated on the analysis of complex morphological variations, or on myological and other anatomical features of only a small number of taxa. Thus, classification attempts often failed because of a lack of holistic background knowledge on functional anatomy, morphology, biogeography and behaviour of the majority of species, leading to phylogenetic misinterpretations due to convergence, parallelism and extreme anagenesis, or evolution towards higher levels of specialization, common phenomena in hummingbirds. Many of the independently evolved structural and functional similarities in trochilids can be explained as adaptations to their highly specialized hovering flight and feeding apparatus, designed to exploit the nectar of angiosperm flowers. Other factors fostering convergence and parallelism are sexual selection pressures on polygamous males by female choice. Thus males of many unrelated species show striking similarities in form and colour of advertisement plumage like crests, gorgets, elongated and variously modified tail feathers, and puff thighs.

Some of the recent studies on hummingbird taxa similarly lack a major prerequisite, namely a sound knowledge of their biogeographical history, allowing the judgement and calibration of character variations within an evolutionary framework. If classificatory studies take account of the evolution of these patterns in time and space, as shown for the Andean *Metallura*, *Chalcostigma* and *Agelaiocercus* complex, the sometimes negatively viewed traditional morphological character analysis may yield valuable information on intraspecific and interspecific phylogenetic relationships, serving as a useful hypothesis to be tested with other methods.

Historically, two subfamilies are generally distinguished within the Trochilidae: the hermits (Phaethornithinae) and the trochilines or typical hummingbirds (Trochilinae). Within these two systematic units, the hermits comprise the six genera *Glaucis*, *Threnetes*, *Ramphodon*, *Eutoxeres*, *Anopetia* (formerly included in *Phaethornis*) and *Phaethornis*, whereas the trochilines form

an assemblage of some 96 genera, which by some authors would be increased to over 100.

Hermits differ from the trochiline hummingbirds by their characteristic humeral tendon and their predominantly pigmentary brownish, greyish and reddish colours. Iridescent colours are sparse and mostly limited to the upperparts. Hermits are generally non-territorial, occur in the understorey of tropical forest or dense scrub, and usually have long bills adapted to flowers with tubular corollas. In all species studied, males gather at leks where they attract females. In their displays, male her-

In 1861, John Gould split hummingbirds into two subfamilies, Phaethornithinae and Trochilinae, and to this day his arrangement stands, mainly for want of consensus on an alternative proposal. The vast majority of species fall into the Trochilinae, a mixed assortment of largely territorial and sexually dichromatic forms. Within this subfamily, the White-bellied Woodstar, belongs in the "starthroat-and-woodstar" assemblage which is linked, amongst other features, by the existence of an eclipse plumage, males often resembling females. This species was previously placed in *Acestrura*, but is now considered to belong in *Chaetocercus*.

[*Chaetocercus mulsant*,
Quindío, Colombia.

Trochilines are generally polygamous, the displays of males often featuring solitary aerial manoeuvres and spectacular plumage traits rather than communal lekking. Within this group, generic limits are poorly understood, a situation highlighted by the fact that around half the trochiline genera are monotypic. With changing taxonomic trends, however, this proportion is gradually declining. The Swallow-tailed Hummingbird, for example, was formerly isolated in *Eupetomena*, but has now been merged with the sabrewings (*Campylopterus*), on the basis of its song structure and the male's thickened primary shafts.

[*Campylopterus macrourus macrourus*, Rio de Janeiro, Brazil. Photo: Luiz Claudio Marigo]

mits employ fanned rectrices and wide-open bills showing the yellow, orange or red interior base of the lower mandible (Gape Display). All known nests of hermits are pendent, often cone-shaped, either attached to the inner tip of a long, narrow, bending leaf or fastened to a vertical root or twig if shelter is provided by a riverbank, cave vegetation, or even a bridge. A recently published careful systematic analysis of these various characters indicates that hermits form a distinct monophyletic group within the Trochilidae.

The more diverse hummingbird subfamily, Trochilinae, is heterogenetic and less distinctive than the hermits. This has led several taxonomists to seek clues allowing further splitting at the subfamily level. For instance, one proposal is to place the coquettes and thornbills in a subfamily, Lophornithinae, and to consider the distinctive members of the genera *Androdon* and *Doryfera* as another subfamily, Doryferinae. Whereas the classification of the Lophornithinae is based mainly on the somewhat superficial location and development of the nasal operculum and the primaries, the Doryferinae are markedly different in their hindneck musculature and song structure from all other previous subdivisions. Systematists agree that the genera *Androdon* and *Doryfera* are not members of the hermit assemblage, to which they were formerly assigned, but their advocated subfamily status should be considered with caution in the absence of detailed comparative anatomical and bioacoustical information. The differences observed in *Androdon* and *Doryfera* may well represent a trochiline-specific early evolutionary state and/or a behavioural adaptation for foraging and communication in forest understorey.

Until our knowledge is improved by further character analyses it seems appropriate to maintain the traditional classification of merely the two hummingbird subfamilies Phaethornithinae and Trochilinae designated by John Gould in 1861.

The Trochilinae comprise about 90% of hummingbird species. They exhibit a trochiline-specific pattern of the humeral tendon. Their often straight to slightly decurved bills range from a few millimetres in the Purple-backed Thornbill (*Ramphomicron microrhynchum*) to 12 cm in the Sword-billed Hummingbird (*Ensifera ensifera*). Most show marked sexual plumage-colour dimorphism. Iridescent bright colours of many metallic shades of red, orange, green and blue frequently occur on the head, upperparts and underparts of males. In some species, jewel-

coloured adornments like expandable gorgets, crests and elongated modified tail feathers are striking male characters. Females are of duller appearance, frequently lacking the brightly coloured feather parts. However, in some species plumage dimorphism is minor or absent, such as in members of the genera *Colibri* and *Eulampis*, where males and females are almost visually inseparable to the human eye. Males of the brightly coloured trochilines are generally territorial; lek behaviour is known only for a few species; and courtship in many non-hermits features characteristic aerial displays. Nests are predominantly cup-shaped and attached to branches or forked twigs, though pendular (*Doryfera*) and domed (*Agelaiocercus*) constructions are known. Trochilines live in extremely diverse habitats ranging from desert borders, mangroves and tropical rainforests to the perennial meadows below the snow-line of high-Andean peaks.

Generic limits and species relationships within the trochilines are still poorly understood. Indeed, many non-hermit genera are based on the same characters that are used to define species. In recent checklists and classifications the lack of synapomorphies at the genus level in trochilines is expressed by over 50% of monotypic genera. All this taxonomic uncertainty presents a considerable challenge for future systematic research.

Despite this problem, several major clades have been identified among the non-hermits. Based on the variation of a single wing muscle, the *Musculus tensor patagii brevis*, three groups within the Trochilinae have been proposed. The first unit covers those genera with a primitive muscle state: *Androdon*, *Doryfera*, *Florisuga*, *Colibri*, *Anthracothonax*, *Eulampis*, *Chrysolampis*, *Polytmus*, *Topaza* and *Heliothryx*. A more advanced muscle state was found in the following genera: *Campylopterus*, *Orthorhynchus*, *Stephanoxis*, *Lophornis*, *Discosura*, *Chlorostilbon*, *Cyananthus*, *Cyanophaea*, *Thalurania*, *Panterpe*, *Damophila*, *Lepidopygia*, *Hylocharis*, *Amazilia*, *Trochilus*, *Lampornis*, and all Andean and North American taxa. The category "highly advanced" muscle state comprises members of the genera *Calliphlox* and *Chaetocercus*.

This single-character arrangement is surprisingly consistent when compared with morphological, morphometric and behavioural information. Using these data sets, eleven distinct taxa can be clustered. Patterns of tail feather coloration, display, and song structure, and a primitive cross-structure feature of the hindneck

While there has been a tendency for some related groups to be merged, other genera have been divided. The best example of this latter phenomenon is the genus *Amazilia*.

Until recently this was considered to consist of a clumsily diverse clade of 28 small species grouped together on account of similarities in nest structure and cervical musculature. Biogeographical analysis suggests that these similarities are superficial and conceal different origins within a polyphyletic assemblage. For this reason *Amazilia* has been split into four separate genera. The six members of the new streamlined *Amazilia*, typified by the Rufous-tailed Hummingbird, have much red in the bill and rufous in the tail. A further six species, including the

Glittering-throated Emerald, have been allocated the genus *Polyerata*. They are unified by a dark upper mandible, a pale ventral region and lack of rufous in the tail. The Andean Emerald belongs in a third genus, *Agyrtia*, comprising nine species with largely white underparts, including the throat. The final nine species have adopted the genus *Saucerottia* characterized by their glossy violet or purplish tails, as illustrated by this Steely-vented Hummingbird.

[Above left: *Amazilia tzacatl fuscicaudata*, Antioquia, Colombia.

Of 23 hummingbirds described to science between 1946 and 1995, only five are still considered valid. The rest have been relegated to the ranks of races, hybrids or aberrant forms. In some cases, however, studies have led to the splitting of previously recognized species. The genus *Aglaiocercus*, for example, was formerly treated as monospecific but is now considered to contain three species, one of which is the Violet-tailed Sylph. While the three are very similar, they differ in plumage coloration, notably in the underparts of females, as well as in size and altitudinal range.

[*Aglaiocercus coelestis* *coelestis*, La Planada Reserve, Nariño, Colombia. Photo: Patricio Robles Gil/Sierra Madre]

muscle (*Musculus splenius capitis*), place the "tooth-bills" *Androdon* and *Doryfera* at the base of the trochiline assemblage, followed by a more derived taxon containing the "sabrewing-and-mango" genera *Campylopterus* (including *Phaeochroa*, *Eupetomena*, *Aphantochroa*), *Florisuga* (including *Melanotrochilus*), *Colibri*, *Anthracothorax* (including *Avocettula*), *Topaza*, *Eulampis*, *Chrysolampis*, *Orthorhyncus*, *Klais*, *Stephanoxis*, and *Abeillia*. This assemblage is characterized by complex cervical musculature, similar patterns of song syntax, and small compact nests of little variation in form and structure, often placed on leaves or saddled on horizontal branches. Probably closely related to the "sabrewing-and-mango" genera are the "coquettes" *Lophornis* and *Discosura* (including *Popelairia*), based on nest shape and male frontal display patterns.

The next taxon comprises the "true emeralds" *Trochilus* and *Chlorostilbon* (including *Chlorestes*). Biogeographical history and plumage features in both males and females already suggested close affinities between members of the West Indian taxa of *Trochilus* and *Chlorostilbon*, an assumption supported by a typical song pattern exhibited during the male display, and also by similarities of nest structure and site. Based on the colour patterns of the rectrices and other morphological features, their closest relatives are most likely the "emeralds" *Panterpe*, *Elvira*, *Eupherusa*, *Goethalsia* and *Goldmania*, followed by the "woodnymph-and-sapphire" clade *Cynanthus*, *Thalurania*, *Damophila*, *Lepidopyga*, *Hylocharis* and *Chrysura*. This latter assemblage shows distinctive cervical musculature, unique flight patterns in the male display, and nest structures with close affinities to the emeraldines. Another unit consists of the "amaziline emeralds" *Leucochloris*, *Polytmus*, *Leucippus*, *Amazilia*, *Agyrtria*, *Polyerata* and *Saucerottia*. Typical nest forms, nest-sites, and a cervical musculature pattern characterize this clade. A recent biogeographical revision of the taxa formerly treated superficially under the genus *Amazilia* postulated a polyphyletic status and various centres of origin around the periphery of central South America. Plumage character analysis suggests ties to *Lepidopyga* and *Leucippus*.

Another distinct taxon also derived from plumage comparisons are the "mountain gems" *Microchera*, *Anthocephala*, *Lampornis*, *Basiliinna* (formerly treated under *Hylocharis*) and *Lamprolaima*.

The "brilliant" *Clytolaema*, *Heliodoxa* (including *Polyplanta*), *Hylonympha* and *Sternoclyta* comprise a further assemblage of closely related taxa. This group is united by typical morphological features like feathered upper and lower mandibles, throat coloration, song and display patterns.

The large "Andean clade" consists of five sub-units: the first contains *Urochroa*, *Boissonneaua* and *Aglaeactis*; the second *Oreotrochilus*, *Lafresnaya*, *Coeligena*, *Ensifera*, *Pterophanes*, *Patagona* and *Sephanoides*; the third *Helianthus*, *Eriocnemis*, *Haplophadna*, *Urochroa* and *Ocreatus*; the fourth *Lesbia*, *Sappho*, *Polyonymus* and *Ramphomicron*; and the fifth *Oreonympha*, *Oxygogon*, *Metallura*, *Chalcostigma*, *Opisthoprora*, *Taphrotesbia* and *Aglaiocercus*. This arrangement is based on the following common features: open wing presentations after perching (especially members of the first, second and third groups); distress calls; perching displays; advertisement songs; plumage characteristics; nest shape; and nest-site.

Finally, another distinct assemblage, the "starthroat-and-woodstar" group, containing *Heliothraupis*, *Rhodopis*, *Thaumatococcus*, *Tilmatura*, *Doricha*, *Calliphlox* (including *Philodice*), *Microstilbon*, *Calothorax*, *Mellisuga*, *Archilochus*, *Calypte*, *Atthis*, *Stellula*, *Myrtis*, *Myrmia*, *Chaetocercus* (including *Acestrura*) and *Selasphorus*. Some of these share similarities in plumage characteristics, notably an eclipse plumage; display pattern features; song structure; flight displays; nest shape; and nest-site.

It should be noted that some of the aforementioned genera are so closely related that their separate generic status is doubtful. The systematic treatment of several other trochiline genera, such as *Heliactin* and *Loddigesia*, is problematic due to lack of data on their anatomy and behaviour. Nest characteristics of *Heliothryx*, another genus with uncertain ties, indicate affinities to the more primitive trochilines like *Colibri* and *Anthracothorax* as well as to *Heliactin*. Another taxon with unresolved phylogenetic relationships is the Central and North American monotypic genus *Eugenes*. Behaviourally, the Magnificent Hummingbird (*Eugenes fulgens*) shows close affinities to the Central and South American genus *Heliodoxa*, but its cervical musculature indicates ties to the North American genus *Archilochus*.

The arrangement of trochiline clades based on comparisons of display patterns, song structure, nest shape, and morphological features should be considered as provisional. Although these

Improved knowledge of the life history of the Black-billed Streamertail of Jamaica has resulted in its formal separation from the Red-billed Streamertail (*Trochilus polytmus*), with which it was considered conspecific. They are closely related and largely allopatric, but in the small area of overlap in the western John Crow Mountains interbreeding takes place only rarely. Even though this decision results in both members of the genus being endemic to one island, they are unlikely to be threatened because they readily tolerate man-modified habitats such as banana plantations and gardens.

[*Trochilus scitulus*,
Port Antonio, Jamaica.
Photo: Robert Tyrrell]

data sets are extremely helpful for the reconstruction of trochiline phylogeny, many of the characters are known only for some taxa but missing for others. Therefore the taxa proposed may stand or fall with further data analyses of homologous characters, a major problem in the evaluation of structure, function or behaviour.

Most promising for a phylogenetic reconstruction of the trochilines seems to be the study of nest structure and nest-site. For each of the eleven trochiline taxa hypothesized, nests show typical patterns within each assemblage. Perhaps the hummingbird family is, like the tyrant-flycatchers, a group for which nest data may be a highly effective tool in reaching an accurate classification. Unfortunately, for several key taxa no nest descriptions exist.

If these preliminary taxonomic divisions, derived mainly from morphology and behaviour, are compared with recent allozyme and DNA hybridization studies (on less than 10% of all hummingbird species), only a few phylogenetic congruencies can be stated with any certainty. The latest molecular data confirm the division of the two basic subfamily lineages, the hermits and the typical hummingbirds (trochilines). Within the trochiline lineage, the relative positions of genera like *Androdon*, *Doryfera*, *Colibri* and *Eulampis* were confirmed, while *Lesbia*, *Coeligena*, *Oreotrochilus* and *Agelaiocercus* appeared as members of the same Andean cluster as that proposed by non-molecular studies. Different to the traditional classification are the relationships of *Chlorostilbon*, *Campylopterus*, *Orthorhyncus*, *Amazilia* and *Thalurania*, as well as that between the Andean assemblage and *Discosura*. Most taxonomists are sceptical of these new findings, particularly since broad generalizations within and between genera are made. Frequently only one species of a genus has been analysed in these studies, with risky extrapolations as to the systematic status of the taxon under consideration, ignoring possible polyphyletic relationships within the genus. It is notable that some results of these molecular biology studies, using similar methods, have led to different branchings for the same trochiline group. Without a representative study of a larger number of replicates covering a larger diversity of hummingbird taxa, formal taxonomic changes based on molecular biology methods should be considered only with caution.

Using plumage characters, there is little disagreement as to which forms of hummingbird should be treated as species. However, problematic specimens or even taxa exist, mostly among trochilines found in museum collections. Some of these enigmatic hummingbirds may be diagnosed as atavistic specimens, hybrids or melanistic morphs of distinct species. An interesting example of the confusion that can be caused is provided by the

Pale-tailed Barbthroat (*Threnetes niger*), which was previously known as *T. leucurus* until it was discovered that the form hitherto listed as *T. niger* was merely a melanistic morph of the same species, with the result that the older name, *niger*, had to replace *leucurus*, since it has priority. The scientific literature refers to dozens of obscure taxa, generally listed as intergeneric hybrids. This high frequency of hybrids between taxa of two genera is often interpreted as evidence that genera are oversplit. However, based on the lack of intrageneric hybrids among North American trochilids it has been assumed that the perfection of intrageneric isolating mechanisms without the concurrent development of intergeneric isolating mechanisms is a major cause of evolutionary change.

It is notable that the North American trochilids of the genera *Archilochus*, *Calypte*, *Stellula* and *Selasphorus*, which regularly hybridize across their generic boundaries, belong to very closely related species within the "starthroat-and-woodstar" lineage. However, hybrids between distinct genera like *Eugenes* x *Cynanthus*, *Heliodoxa* x *Heliangelus*, and *Agelaiocercus* x *Thalurania* have been identified. Recently it has also been shown for the Phaethornithinae that regular intrageneric hybridization occurs, but due to plumage similarities among parent birds parentage can only be determined by means of detailed biogeographical and morphometric information. With a better knowledge of hummingbird phylogeny, hybridization at different taxonomic levels may contribute to our understanding of generic relationships.

Biogeographical studies combined with morphological parameters may reveal more cases of hybridization, especially when only single specimens of a taxon are known, as in the eastern Venezuelan "Amazilia distans", now considered a hybrid between race *elegantissima* of the Glittering-throated Emerald (*Polyerata fimbriata*) and race *viridiventris* of the White-chinned Sapphire (*Hylocharis cyanus*).

During the period 1946-1995, altogether 23 hummingbird species new to science were described, with eight in Phaethornithinae and 15 in Trochilinae. After critical revision only one of the hermits, Koepcke's Hermit (*Phaethornis koepckeae*), was considered a valid species, while only four remained on the list of trochilines, namely the Royal Sunangel (*Heliangelus regalis*),

Because of considerable morphological differences, the Ecuadorian Hillstar has been split from its relative, the Andean Hillstar (*Oreotrochilus estella*), to form a pair of allospecies. They inhabit the windswept páramo at high altitudes, where the bulk of their diet is derived from the flowers of composite shrubs, on which they often prominently perch, as illustrated by this female. Like most hummingbirds, they are largely solitary but considerable aggregations sometimes gather at superabundant nectar sources. In addition, both species sometimes roost and nest semi-colonially in caves, presumably for shelter in their open montane environment.

[*Oreotrochilus chimborazo jamesonii*,
Papallacta Pass, Ecuador.
Photo: Luis Mazariegos]

Colorful Puffleg (*Eriocnemis mirabilis*), and Perija (*Metallura iracunda*) and Neblina Metaltails (*Metallura odomae*). The others turned out to be subspecies, hybrids, aberrant individuals, immatures, or synonyms of known subspecies.

The Chiribiquete Emerald (*Chlorostilbon olivaresi*), described in 1996 by F. G. Stiles, is presently considered a valid species but

may in the future end up being treated only as a subspecies of the Blue-tailed Emerald (*Chlorostilbon mellisugus*), once more detailed information on geographical character variations are available and zones of contact within this complex are better understood.

It is highly likely that some new hummingbird species will be discovered in forthcoming years, since many areas, especially in the Andes and isolated Andean foothills, are still ornithologically unexplored. Further life-history knowledge may also reveal that some of the known taxa, currently treated as subspecies, have successfully developed reproductive isolating mechanisms, thus calling for their recognition as full species, as was quite recently the case of the Red-billed (*Trochilus polytmus*) and Black-billed Streamertails (*Trochilus scitulus*).

Besides these general speciation problems for taxonomists, more basic taxon-related questions in hummingbirds still remain unanswered. Females are unknown for several taxa, such as the Coppery Thorntail (*Discosura leucophaea*) and the Sapphire-bellied Hummingbird (*Lepidopygia lilliae*). Some taxa such as the Turquoise-throated Puffleg (*Eriocnemis godini*), Black-backed Thornbill (*Ramphomicron dorsale*) and several others have not been sighted for decades. They may have survived in remote and inaccessible places or may be extinct, as seems to be the case with the possibly hybrid Bogota Sunangel (*Heliangelus zusii*) from the eastern Colombian Andes, and also with Brace's Emerald (*Chlorostilbon bracei*) from New Providence, Bahamas, not seen again after its discovery in 1877 (see Status and Conservation). The very absence of recent records and material for such forms makes it extremely difficult for any advances to be made regarding their taxonomy, as is certainly the case of the possible species "*Saucerottia alfaroana*", of which there are no recent records, and which may be extinct. Differing opinions consider this form to be a genuine species, or to belong either in the Indigo-capped Hummingbird (*Saucerottia cyanifrons*) or in the Steely-vented Hummingbird (*Saucerottia saucerrottei*), but the chances of its being an aberrant individual or of hybrid origin equally remain open.

Morphological Aspects

Hummingbirds are extremely small. Most species are 6-12 cm in size and have a body mass of around 2.5-6.5 g. The Reddish

The taxonomy of the Variable Mountain-gem is highly controversial. Herein it is treated as a composite of three parapatric groups that are sometimes recognized as full species: the purple-throated, blue-tailed calolaemus group; the white-throated, grey-tailed form cinereicauda; and the white-throated, blue-tailed form castaneoventris. Females of all three are virtually identical, while hybrid zones occur in areas where their ranges meet. Research has shown the sexes to be ecologically separated, feeding on nectar at different vegetational strata, the female tending to feed much lower down.

[*Lampornis castaneoventris*, Costa Rica. Photo: Michael Fogden/Oxford Scientific Films]

Small size is a famous feature of most hummingbirds, but the diminutive Bee Hummingbird takes smallness to extremes. Weighing about 2 g, the male is the lightest bird in the world, easily mistaken for an insect as it whirrs slowly around the blossom of Aloe and Hibiscus in its native Cuba. The male's glittering red gorget and lateral plumes distinguish him from the dull plumaged but slightly larger female.

[*Mellisuga helenae*, Playa Larga, Zapata Swamp, Cuba. Photo: Robert Tyrrell]

Hummingbirds have perfected the art of hovering in order to exploit the rich nectar resource of flowering plants in the New World.

The birds can remain apparently motionless in mid-air for quite some time, their wingtips executing rapid figures-of-eight, as partly captured on this Green-backed Firecrown. During foraging flight, 10-80 wingbeats per second are the norm, although up to 200 beats per second have been recorded during displays.

Unlike other birds, the Trochilidae use both the upstroke and the downstroke to power their flight.

[*Sephanoides sephaniodes*, southern Chile.

Photo: Günter Ziesler]

Hermit (*Phaethornis ruber*) from Guyana and Brazil and the Bee Hummingbird (*Mellisuga helenae*) of Cuba each weigh less than 2 g (1.6-1.9 g), while members of the genera *Eutoxeres*, *Ensifera* and *Pterophanes* are heavier than average at 12-14 g. As its name suggests, the largest of all is the Giant Hummingbird (*Patagona gigas*), weighing 19-21 g, comparable in size to a swift.

Trochilids are highly evolved nectarivores, depending almost completely on the carbohydrate-rich sugar secretions (nectar) of ornithophilous flowering plants, the approximate composition of their diet being 90% nectar, and 10% arthropods and pollen. They reach this liquid food with thin, elongated bills of various shapes, which protect their specialized long, sensitive tongues. Their feeding behaviour necessitates a specific locomotor performance,

namely hovering flight, which allows them to remain apparently motionless in the air when feeding on exposed flowers, but, due to this unique foraging behaviour, they can no longer walk or climb with their feet, which serve only for perching. During hovering, their pointed, uncambered wings are moved mainly in the horizontal plane, describing with their tips a flat figure of eight, in the manner of a variable-pitch rotor. By slightly altering the wing angle, this technique allows all kinds of controlled forward, sideward and backward movements in the air, including upside-down manoeuvres.

While hovering, the wingbeat rate in smaller trochilids like the Amethyst Woodstar (*Calliphlox amethystina*) averages 70-80 per second compared to 10-15 in the Giant Hummingbird.

Supremely manoeuvrable, all hummingbirds can control their position and orientation with minute adjustments in the angle or strength of their wing strokes, often performing acrobatics to access hidden nectar reserves.

The Stripe-tailed Hummingbird, here demonstrating its flying skills at a passionflower (*Passiflora*), is found mainly in moist montane forest in Central America, where it feeds at flowering trees, epiphytes and shrubs.

[*Eupherusa eximia egregia*, Costa Rica. Michael Fogden/DRK]

The hermit subfamily, Phaethornithinae, is separated from the typical hummingbirds of the Trochilinae, its members differing chiefly in their unique humeral tendon, their dull colours and their distinctive habit of constantly tail-wagging when perched. The vast majority of hermit species inhabit the forest understorey, where they are non-territorial and display at leks, features only shared by a few trochilines. In their displays, male hermits usually form loose aggregations, fan their rectrices and call with wide open bills revealing their brightly coloured gapes. The Green Hermit, like most of its relatives, has developed a long bill adapted for insertion into flowers with elongated corollas. The hovering flight of both hermits and trochilines is facilitated by skeletal design. While most birds have six pairs of ribs, hummingbirds possess eight, along with a deeply keeled, elongated sternum to which powerful flight muscles are attached. The sternum has a shallow cup-and-ball joint where the strong coracoid bones are connected, a design shared only by the swifts. The "arm-bones" of hummingbirds are truncated while the "hand-bones" carry ten large primaries, increasing steadily in size towards the outer edge of the wing. The number of secondaries is much reduced, there being six or sometimes seven, compared with the usual nine of most passerines.

[*Phaethornis guy emiliae*,
Valle, Colombia.
Photo: Luis Mazariegos]

The feet of the Black-crested Coquette have been reduced to very weak appendages that are useless for hopping, walking or climbing.

This is true of all hummingbirds because of their reliance on hovering and the constraints imposed by associated flight dynamics. In addition, hummingbirds and swifts possess complex cervical musculature, the function of which is unclear. It may relate to the control and speed of head movements, which are important for trapping mobile insect prey, but as insects only make up a rather small part of the diet of hummingbirds, there might be other benefits for aerial nectarivores.

[*Lophornis helenae*,
Costa Rica.

Bruce Coleman]

During the courtship flights of some North American trochilids, such as the Ruby-throated Hummingbird (*Archilochus colubris*) and the Rufous Hummingbird (*Selasphorus rufus*) wingbeat rates of over 200 per second have been reported. The humming sound produced by the wings during hovering has given the family its English name.

Flying speeds under controlled laboratory conditions range roughly from 48 to 85 km per hour. For the Green Violet-ear (*Colibri thalassinus*), in the wild, a velocity of 96 km per hour has been recorded, and during short chase flights up to 150 km per hour. The homing pigeon, a domesticated form of the Rock Dove (*Columba livia*), and one of the most skilful and rapid fliers among birds, travels at speeds of around 64 km per hour.

The unique flight mode involves specific skeletal and flight-muscle features. The deeply keeled and elongated hummingbird sternum is relatively large compared with those of other flying birds. Eight pairs of ribs, two more than in most birds, help to stabilize the body during flight. Exceptional in structure are the strong coracoids of the pectoral girdle. Only hummingbirds and swifts have a shallow cup-and-ball joint where the coracoids are connected to the sternum. Tendons connect the flight muscles with the humerus.

The arm bones of all trochilids, consisting of the humerus, radius and ulna, are much shortened, with the result that over 70% of the wing skeleton size is attributable to the elongated hand bones, homologous to the second, third and fourth fingers of the tetrapod hand.

The modified humerus bone of hummingbirds moves freely at the shoulder joint, permitting optimal wing movement in all directions, including axial rotations of nearly 180 degrees. It is only the humerus that moves at this joint. Slow motion pictures, however, indicate little flexure of the short arm bones.

The hand bones bear 10 large flight-feathers, the primaries, increasing progressively in size from the inner portion of the wing towards the tip. There are only a few exceptions to this general size scheme, such as in the Broad-tailed Hummingbird (*Selasphorus platycercus*) and the two Jamaican *Trochilus* streamertails, with their somewhat reduced outer primaries. In the case of the Broad-tailed Hummingbird these form modified thin wingtips creating a specific mechanical flight sound. In the streamertails, the sound source sometimes attributed to the reduced outermost primaries is still debated, but most likely this mechanical flight noise is generated by the scalloped and fluted pair of elongated tail feathers. Another unusual group of

trochilines, with up to three modified outermost primaries, is the sabrewing assemblage (*Campylopterus*). Their feather shafts are thickened to various degrees, mainly in males, possibly contributing to a strengthening of the wing during their fast, swift-like gliding among semi-open vegetation, a common feature of these hummingbirds.

The two major muscles for trochilid flight are the mitochondria-rich *Musculus pectoralis major*, attached to the sternum, clavicle and humerus, and the *Musculus supracoracoideus*, lying beneath the pectoralis and also attached to the sternum. Both muscles consist exclusively of dark red fibres, providing the en-

In spite of their feet being tiny, hummingbirds use perches frequently, particularly when suitable sites are provided by favoured food plants, such as *Heliconia*.

The distinctive Buff-tailed Sicklebill is celebrated for its startling bill morphology, a design that allows it to harvest the nectar of similarly curved *Heliconia* and *Centropogon* flowers.

This species is not exclusively reliant on humid forest, also occurring in open habitats and areas that are cultivated or disturbed.

ergy for powerful flight. The large pectoralis pulls the wing down, whereas the antagonistic supracoracoideus raises it. Since wing movement during hovering is extremely energy-demanding the supracoracoideus is also large, amounting to about 50% of the size of the pectoralis. Thus hummingbirds use the upstroke and downstroke almost equally for powered flight, in contrast to most other birds which mainly employ the downstroke for their powered flight. Both flight muscles together make up over 30% of the body mass of a hummingbird, much more than in other strong fliers such as migratory birds, in which these muscles account for about 20% of body mass.

As tiny endotherms, hummingbirds suffer from low thermal inertia and high heat loss. Flapping flight is energetically expensive, and convective cooling caused by wing and air movements can further exacerbate energy loss. Energy conservation during flight is thus an important physiological problem for hummingbirds. Studies by P. Chai and his co-workers revealed that trochilids clearly use the heat produced in flight to contribute to their thermoregulatory requirements during hovering. If oxygen consumption is used as an estimate of metabolic cost, it was demonstrated that in hover-feeding, oxygen consumption increased only moderately between 5°C and 35°C, in contrast to the drastic increase during perch-feeding by hummingbirds over the same temperature range. Heat production by contraction of the flight muscles is employed as a substitute for regulatory thermogenesis to compensate for heat loss during exposure to cold. The mechanical power requirements of hovering decrease slightly with declining air temperatures, but metabolic costs increase. Thus the mechanical efficiency of muscles in converting metabolic power into mechanical power is reduced. Changes in wingbeat kinematics also accompany this reduction in muscle efficiency. Wingbeat frequency increases but stroke amplitude decreases when hovering at low temperatures, indicating a thermoregulatory role for the flight muscles. It has been suggested that a modulating of muscle efficiency and heat production may allow flying hummingbirds to achieve energy conservation during cold conditions.

Hummingbird flight muscles are extremely oxygen-dependent. Mitochondrial volume density in these muscles can account for 35% of their volume; this figure may represent an upper limit because any further increase would reduce space for the muscle fibre necessary for mechanical work. However, even during hov-

ering, trochilids are operating within a reasonable physiological safety margin. These physiological reserves are essential for maintaining fitness parameters. A steep decline in hover-feeding duration with decreasing oxygen density has been observed in the laboratory for the Sparkling Violet-ear (*Colibri coruscans*) of South America. This fairly large montane species was capable of hovering at simulated altitudes of over 6000 m with only a slight increase in oxygen consumption of 6-8%. Recently it has been discovered that this increase at low air densities (high altitudes) matched the required increase in flight power output, resulting in a constant muscle efficiency of 10-11%, assuming perfect elastic energy storage.

Another specialized trochilid muscle is the heart. It amounts to about 2.5% of a hummingbird's body mass, whereas in small songbirds, like the House Sparrow (*Passer domesticus*), it contributes 1.3% of the weight, and only 0.5% in primates. A hummingbird's heart beats 500-600 times per minute while the bird is resting, and over 1000 times per minute during aggressive encounters. In a ratite like the Ostrich (*Struthio camelus*) the normal heart rate ranges around 40-180 beats per minute.

The peculiar crossover origin of the cervical *Musculus splenius capitis*, attached to the second vertebra, is a complex myological feature found in hummingbirds and swifts (see Systematics). The function of this muscle has been a matter of speculation since the discovery of its cruciform emergence by P. J. K. Burton in 1971. In hummingbirds and swifts it is most likely that this muscle type ensures faster sideways head movements than can be made by species with a *Musculus splenius capitis* attachment to the neural spine, as in passerines for example, where the shorter fibres of this muscle imply relatively slower head movements; in these taxa, the central emergence of this muscle mainly supports up-and-down movements of the head. Hummingbirds and swifts feed on insects at high flight velocities. Since they can recognize their prey only at short distances, high-speed head movements are required to select and capture suitable food.

All contour feathers of trochilids are connected to cutaneous muscles which co-ordinate feather movements like fluffing or ruffling for thermoregulation and comfort behaviour, as well as the expansion of iridescent gorgets or rectrices as specific recognition signals during territorial defence or flight display.

The reduced wing bones of trochilids normally carry six, occasionally seven, short inner flight-feathers, the secondaries.

One of the shortest bills of any hummingbird is that of the Purple-backed Thornbill. It is used to obtain nectar from a wide variety of small-flowered shrubs and even large flowers, utilizing holes at their bases made by *Diglossa flowerpiercers*. It is also used for capturing insects. The energy required to fuel the intense muscular activity of hovering flight is derived from carbohydrates in nectar. A hummingbird's heart accounts for about 2.5% of its mass, around double the normal proportion for birds and five times that of primates. To meet the high oxygen needs of their lifestyle, it beats 500-600 times per minute when the bird is perched.

[*Ramphomicron microrhynchum*.
Photo: A. J. Mobbs/Aquila]

Hummingbirds consume nectar with the use of an extendable bifurcated tongue. While the base is partly cartilaginous, the tip is divided lengthwise to form two separate membranous curled troughs. Nectar passes into these grooves by way of capillary action and the tongue is flicked 3-13 times per second. The function of the mandibles in the nectar-drinking process remains unclear, although it appears that they might be pressed together to squeeze nectar from the tongue. Equally, the tongue might be stretched slightly, as by this Berylline Hummingbird, to constrict the capillaries and thus flush nectar into the throat.

Most trochiline species, such as these Rufous Hummingbirds, are sexually dimorphic, males usually being considerably brighter than females.

Energy conservation presents an important physiological problem to flying hummingbirds, especially at the high latitudes where this species breeds.

When temperatures are low, the contraction of flight muscles assists with thermoregulation by compensating for heat loss. Individuals also tend to increase their rate of wingbeats but decrease the amplitude of each beat, thus increasing heat production while maintaining controlled flight.

Differences of flight specialization in birds result in a variable number of secondaries, whereas the number of ten primaries remains fairly constant, except for grebes (Podicipedidae), storks (Ciconiidae) and flamingos (Phoenicopteridae) with eleven primaries and the New World nine-primaried songbirds, like tanagers (Thraupidae), wood-warblers (Parulidae) and buntings (Emberizidae). A soaring flight specialist like the Wandering Albatross (*Diomedea exulans*) has ten primaries but 37 secondaries, while most passerines have only nine secondaries.

The number of tail feathers or rectrices in hummingbirds is almost invariably 10, except for the Marvellous Spatuletail (*Loddigesia mirabilis*) of Peru which has only four. In adult males of this species, one pair is highly modified with a forward-curved quill ending in a fairly large racket. Tail feathers play an important role in all flight manoeuvres. They are essential for lift and balance during quick flight movements in dense forest undergrowth, and for progressive or abrupt changes from fast forward to hovering flight.

Hummingbirds' tails differ greatly in size and shape. They can be forked, V-shaped, rounded or wedge-shaped. In several species of the genera *Lesbia*, *Trochilus* and *Thaumastura*, for example, some of the tail feathers are strikingly elongated, the same length or even twice as long as the actual body size of the bird. Others, like the Racquet-tailed Coquette (*Discosura longicauda*) and Booted Racquet-tail (*Ocreatus underwoodii*), carry little flags at the end of a single pair of extended rectrices.

Unlike their rectrices, hummingbirds' wings often appear rather dull since the colour of the remiges is pigment-based, as in almost all other birds. Exceptions are the brightly shining wing-coverts of many species and the iridescent flight-feathers of the Purple-throated Carib (*Eulampis jugularis*). The lack of iridescent colours in primaries and secondaries is obviously an adaptation for flight, since a characteristic anatomical feature of feathers producing structural colours is the absence of hooklets between the barbules, reducing the mechanical strength of the feather vane.

Another major feature of trochilid plumage is the striking iridescent colours of crests, gorgets, rectrices and other feather structures. In contrast to colours generated by pigments, iridescence is of a physical nature, caused by the structure of platelets in the feather barbules. Beneath the upper surface of these platelets we find thin elliptical bodies of melanin filled with air bub-

bles. These form a mosaic-like non-homogenous layer of up to ten, stacked one above the other within a barbule. The platelets are only 2.5 microns in length with a thickness averaging 0.18 microns. The melanin matrix of the platelets has a refractive index of 2.2, the air bubbles inside of 1.0. With varying air volume in the platelets, different composite refractive indices are created, ranging from 1.85 at the red end of the spectrum to 1.5 at the blue end. C. Greenewalt discovered by electron microscopy that the thickness of the platelets influences not only the properties of the perceived light, but also those of the air held inside each pigmented body, thus causing variations in interference effects. Each pigmented body within a platelet can produce differ-

Hummingbirds' tails differ greatly in size and shape, but they generally function in flight control and manoeuvrability. In particular, they assist with lift and provide balance during adjustments between direct and hovering flight.

The tails of several species, such as the Empress Brilliant, are deeply forked, which maximizes flight control while minimizing drag.

This highly iridescent species has a restricted range in western Colombia and Ecuador, where it is locally common in the forests of wet foothills and lower mountains.

[*Heliodoxa imperatrix*,
Río Nambi Reserve,
Nariño, Colombia.

ent colours depending on the angle from which it is viewed. Thus, a throat may appear metallic golden if a beam of light comes from directly behind the observer, but will shift to almost black if the angle of view is changed. In summary, media of two different structures are necessary to produce interference. In hummingbirds these are mainly the upper surface of the barbules and the air-containing cells of the platelets. When light waves are reflected from such a bi-medium structure so that the crest of one wave coincides with the trough of another of the same wavelength, then they neutralize each other. Other wavelengths then effectively stimulate colour vision.

Hummingbird coloration is related to behaviour. Generally two broad groups of coloration characteristics can be distinguished in birds: those promoting concealment and those enhancing conspicuousness. The majority of trochilid females exhibit a cryptic coloration. This may be viewed in the light of predator-prey relationships, since all activities associated with nesting and the rearing of the young are carried out by the female alone. Conspicuous female coloration would easily betray the bird and the nesting site to potential predators. Males of many species of open habitats often show phaneric coloration, which makes them stand out as much as possible. As part of their territorial and polygamous life-history, bright, light-dependent iridescent colours on the throat, crest or back play important intraspecific and interspecific roles as visual threat signals for territorial defence, self-advertisement during display, or species-specific recognition cues. Since colour signals are effective only at close range, hummingbird visual behaviour is often accompanied by a complex vocal repertoire and/or mechanically produced sounds. In forest-dwelling species, like most members of the Phaethornithinae, sex-specific phaneric iridescent coloration is absent. This may be explained by the dimly lit undergrowth of their tropical forest habitats and by their non-territorial foraging behaviour.

Hummingbirds lack downy feathers when adult. Some sparse natal down occurs in a few longitudinal rows on the upperparts of nestlings. These neossopiles, normally light beige or dull greyish in colour, remain attached to the contour feathers during the nestling stage, where they serve as triggers to release gaping (see Breeding). They are shed some weeks after fledging.

Trochilids have proportionally few contour feathers, roughly in the range of 900-1700, about 4-7 times less than passerines of similar size. This is considered to be an adaptation to high heat production during flight. Heat dissipation is much easier to regulate with less feather insulation.

The plumage of immature males and females is mainly similar to, but duller than, that of adult females. Immatures moult into adult plumage in their first year. In only a few sexually dimorphic species, like the Jamaican streamertails and the Juan Fernandez Firecrown (*Sephanoides fernandensis*), male and female nestlings can already be clearly separated by their plumage, which is similar to that of adults but less bright in coloration.

Hummingbirds have a single complete annual moult, starting soon after the breeding season. Replacement is slow and takes several months: post-juvenile moult takes around four months, annual moult about 4-5 months. The post-juvenile moult is lacking in the Western Long-tailed Hermit (*Phaethornis longirostris*) of Central America, formerly considered as conspecific with the Eastern Long-tailed Hermit (*Phaethornis superciliosus*), and it may also be absent in other lekking tropical species. In general, the flight-feather moult of hummingbirds resembles that of most other avian taxa. Primaries are replaced in descendant sequence, starting from the innermost and moving to the outermost. However, only trochilids invert the moult of the outermost two primaries (P1-P8, P10, P9), which are crucial in maintaining aerodynamic stability of the wingtip during hovering flight. Moult of secondaries follows in a centripetal order, and with a high degree of individual variation following the replacement of the majority of the primaries. This is also a common moult pattern in most birds to avoid creating gaps in the flight surface. The renewal of the rectrices, usually replaced from the centre outwards, is different in trochilids. The outer rectrix is normally moulted earlier in the sequence rather than last. Bilateral asymmetry of the replacement of rectrices and secondaries is common. Body moult is initiated with the shedding of the primaries and continues until their replacement is completed, though with much individual variation. In several hummingbird species the wing-coverts and tail-coverts are moulted simultaneously with the replacement of primaries, but their moult is complete before that of the flight-feathers. Moult of iridescent feather parts on the throat, chin, forehead and crown of males is often completed several weeks after renewal of primaries. It has been suggested that the delayed moult of brightly coloured feathers ensures that the bird enters the subsequent breeding season in optimal plumage condition.

An interesting moult pattern has been observed in the Western Long-tailed Hermit in Costa Rica. Although most of the population in one study moulted at the same time in different years, moult cycles of several individuals were as much as six months out of phase. Furthermore, the study, by F. G. Stiles and L. L. Wolf, revealed that at the individual level there was no consistent temporal relationship between moult and the onset of breeding. Males occupied lek territories during much or all of their moulted period, while some females interrupted their slow moult for

A characteristic feature of hummingbird plumage is the iridescent colouring present in many species. Unlike the coloured feathers of most birds, iridescence is a physical, rather than pigment-related, property. Beneath the upper surface of platelets in the feather barbules is another layer comprising air-filled melanin bodies. When light is reflected from this double surface, it is neutralized by interference allowing other wavelengths to stimulate colour vision. The plumage of most hummingbirds is usually green or blue, or a combination of these as in the Purple-crowned Woodnymph.

[*Thalurania colombica colombica*, Santa Marta, Colombia. Photo: Luis Mazariégos]

The Blue-throated Starfrontlet has a coppery vent, bright purple belly, green breast and head with a bright blue throat, when viewed from appropriate angles. The wing feathers are quite dull, however. Iridescence tends to be restricted to body or tail feathers of hummingbirds, as the design of shining feathers precludes the presence of hooklets between barbules, which in turn reduces the mechanical strength of the feather.

[*Coeligena helianthea helianthea*, Laguna Chingaza, Cundinamarca, Colombia. Photo: Luis Mazariégos]

Hummingbirds are famed for the startling beauty of their plumage.

In general, this gaudy attire is exclusive to males, as their mates carry the burden of parental duties. While incubating and feeding young, they rely on crypsis as a defence against predation. Males are less constrained by predation costs and have developed fabulous coloration, which functions in various communication systems. During territorial or courtship displays these plumage traits are used as cues to signal identity, dominance and quality.

As the physiological production of iridescent plumage is theoretically costly, shiny plumage might act as an honest signal of individual quality, with poor males unable to meet the cost of production and therefore easily recognized by potential mates.

Iridescence is most frequent in territorial hummingbirds of well-lit habitats while non-territorial denizens of dark understoreys, such as the Phaethornithinae, often lack iridescence.

Amongst the brightest members of the family are the Green-crowned Brilliant, the Crimson Topaz and the Ruby-topaz Hummingbird. The moult of brightly coloured body feathers often occurs several weeks after the replacement of flight-feathers, perhaps to ensure that they are in prime condition at the outset of the breeding season.

breeding. The researchers concluded that a moult-breeding overlap enables the species to reproduce at any time when environmental conditions, such as food supply, are most favourable.

The degree of individual variation and the differences during annual hummingbird moult sequences suggest a genetic or physiological moult-site initiation adjusted to temporal variables and local effects rather than a predetermined, genetically fixed rhythm for each feather follicle.

Nectar supplies the necessary energy for the highly evolved muscular system of trochilids. Hummingbirds take up nectar using their extendable bifurcated tongue, which is forced out of the bill by the hyoid apparatus stretched around the posterior part of the skull. The proximate half of the muscular tongue is partly cartilaginous. The distal half is divided lengthwise, forming two separate membranous curled troughs. This frontal part is essential in nectar drinking, since the liquid nectar is carried into the external troughs by capillary action. The amount of liquid food taken depends on the size of the distal troughs, which increase linearly according to tongue length. In the Ruby-throated Hummingbird each groove may hold up to 0.4 microlitres. It has been shown experimentally that during nectar consumption the grooves on the hummingbird tongue may play only a minor role when large volumes of nectar are available, but they are of importance for emptying small volumes of nectar in flowers. The rate of tongue licking varies from 3 to 13 licks per second. In nature, corolla curvature, position, and nectar volume are important factors in determining nectar extraction rate from flowers. As a general rule, hummingbirds drink their body mass of nectar in several hours.

The exact functioning of the upper and lower mandibles in drinking is not fully understood. One suggestion is that the liquid-filled tip of the tongue is actively emptied by bill constriction, or that the nectar is squeezed from the capillaries by stretching the tongue partly out of the slightly opened bill. Probably both actions are operative.

The first ornithologists to study hummingbirds supposed that the forked tip of the tongue had a sticky surface working as a glue to trap insects. However, this nectar-specialized feeding apparatus is completely unsuited for the capture of insects hidden inside flowers. Insects providing most of the protein in the hummingbird diet are caught by hawking, or by gleaning from vegetation or from spider webs. Hawking is common in short

and straight-billed species, whereas long-billed species like hermits (Phaethornithinae), incas and starfrontlets (*Coeligena*) are specialized insect gleaners. In many species like the coronets (*Boissonneaua*), metaltails (*Metallura*) and trainbearers (*Lesbia*), both methods can be observed.

Nectar also supplies the necessary energy for growth and renewal of body tissue, maintenance of body temperature at 40–42°C (endothermy) and other important biological functions including reproduction. Since hummingbirds have the highest mass-specific basal metabolic rates of all birds, their digestive system is well adapted to break down food as quickly as possible and to absorb the nutrients contained therein.

The alimentary system consists of the buccal apparatus, comprising the bill, the mouth with rudimentary salivary glands and a few taste buds, and the tongue. Another sub-unit consists of the oesophagus and the crop, a sac-like thin distension where solid food (insects, spiders, pollen) is moistened and softened with mucus. A specific feature in trochilids is the proximity of the entrance of the first stomach section to the exit of the second. Nectar therefore immediately reaches the short small intestine where it is absorbed. Only solid food particles enter the first part of the stomach, the proventriculus, where they are mixed with more mucus, hydrochloric acid and pepsin. Here begins the digestion of protein, to be continued in the second part of the stomach, the ventriculus, where muscular contractions ensure the necessary mixing of the pepsin with its substrate. In trochilids the ventriculus is smaller than the proventriculus. From the ventriculus food passes to the short small intestine, the duodenum and ileum, where liver bile and pancreas enzymes contribute to the main phase of chemical digestion. Nutrients are absorbed quickly by intestinal tissue and released to the bloodstream. Indigestible material is passed on to the reduced large intestine (colon and cloaca) where water reabsorption takes place before faeces are secreted together with urine via the cloaca.

The carbohydrate-rich sugars of the nectar are passed directly to the small intestine, without entering the stomach, where they are quickly digested. The intestinal transit time is often less than 15 minutes. In this short time hummingbirds succeed in extracting up to 99% of the ingested sugar glucose. This is possible because of the very high number of glucose transporters per quantity of intestinal tissue, most likely the highest number in all vertebrates.

Not all hummingbirds are bright, and some, such as the Buff-breasted Hummingbird of northern Colombia and Venezuela, are inexplicably dull.

This species inhabits arid thorny scrub and subdesert habitats, foraging on the flowers of xerophytic plants such as Agave and Opuntia. As congeners that inhabit forest are considerably more colourful, it has been postulated that brightness may be environmentally mediated, and less likely to occur in bleak or open situations. This relationship does not hold true in all genera, however.

Amongst the most frequent plumage signals in the family are the glossy facial markings of many males. The male Brazilian Ruby, for example, develops a violet throat patch and an iridescent green forehead, whereas females are uniformly rufous below and duller above. This species is restricted to south-eastern Brazil where it is common, tolerating disturbed habitats, attending hummingbird feeders around major cities such as Rio de Janeiro, and occupying territories in the understorey of humid forests.

[*Clytolaema rubricauda*, Espírito Santo, Brazil.
Photo: Luiz Claudio Marigo]

One of the interesting features of iridescence is the variability of perceived colours according to the angle from which feathers are viewed. The frontal "visor" of this male Hyacinth Visorbearer, for example, appears black when viewed from the side, but turns shining green when the head turns towards the observer.

This has the added advantage of being a focused signal, "switched on" when the bird faces an intended recipient, and "switched off" when it chooses to look away, perhaps a factor underlying the prevalence of facial iridescence in the family. This species is restricted to central Brazilian hills and plateaux, where it abounds locally in low vegetation, feeding at flowering bromeliads and cacti.

It takes about four minutes for a hummingbird to empty its crop of a nectar meal into the intestine. Crop-emptying is in turn limited by the ability of the intestine to absorb the nutrients contained in the nectar. It has therefore been suggested that the density of glucose transporters in trochilids is the maximum structurally possible for any intestinal membrane. Digestive physiology obviously limits the feeding rate of hummingbirds, just as it does in ruminants like cows, though for very different reasons.

Unlike many other birds, hummingbirds have no caeca; these are short projections of the large intestine that provide a further bacteriological digestion of nutrients. Caeca are common in birds feeding primarily on plant material, like galliforms, which degrade plant particles to volatile fatty acids by means of bacteria. A further anatomical peculiarity of those trochilids studied so far is the absence of a gall bladder.

The liver of hummingbirds is able to store large quantities of lipids and glycogen. In species like the Ruby-throated Hummingbird, these important energy reserves account for 45% of total liver mass at the beginning of migration. In non-migra-

tory tropical species liver lipid reserves amount to about 6% of their mass.

Due to their energy-demanding hovering flight, hummingbirds have the highest oxygen requirements of all vertebrates. Their respiratory system, two compact symmetrical lungs for gas exchange and nine thin-walled air-sacs acting as bellows for their ventilation, is adapted to utilize high gas volumes. At rest, the breathing rate is 300 times per minute, which may rise under heat conditions or during hovering flight to over 500 per minute, whereas a starling or a pigeon breathes roughly 30 times per minute, and man about 14-18 times per minute. The tidal volume of each respiration act ranges in trochilids from 0.14 to 0.19 cm³, which is 100% higher than in mammals of similar size (shrews).

Air enters the body through two nostril slits at the proximate part of the maxillary, flowing to the nares and the pharynx, entering the glottis at the base of the tongue into the upper end of the windpipe, or trachea. The glottis has a long slit without a protective cartilage flap and is compressed by rapid reflex movements, preventing solid particles from entering the

Investigation has shown that hummingbirds' eyes possess a visual pigment which is sensitive to ultraviolet (UV) light. This might be especially important in identifying rich nutrient sources, especially as flowers in their fertile phase are known to exhibit UV-specific colour patterns. Moreover, as the spectral reflectance of iridescent plumage includes UV wavelengths, glossy plumage signals may be even more conspicuous to hummingbirds than they are to humans. Male Costa's Hummingbirds vigorously defend territories encompassing flowering shrubs, often using regular perches from which they scan for potential mates and intruders, and sally after flying insects.

trachea. The trachea channel consists of cartilaginous rings, with fibrous tissue in between, providing the necessary flexibility during locomotion. When passing through the wishbone the trachea bifurcates into two tubes, the primary bronchi, each of which goes to one lung. These then give rise to the first set of secondary bronchi on the backward side of the lungs, spreading over the ventral surface and transporting air to the cranial air-sacs. The primary bronchi continue to the lower backward

side giving off a second set of secondary bronchi, which spread out over the inner surface of the lung. At the caudal lung margin the primary bronchus ends in the abdominal air-sac. The sets of secondary bronchi are connected to capillary vessels where the gas exchange takes place.

Respiratory movements in trochilids and most other birds are independent of flight movements. They are produced by the rib and abdominal wall muscles, which are isolated from the large flight muscles. These discoveries have been made by recording wingbeats and breaths and noting different relationships between them, ranging from 3:2 to 5:1.

Like most avian groups, trochilids depend on their eyes while flying, and rely on vision for finding food sources or for recognizing predators, food competitors, and mates. Since hummingbirds are diurnal their sight is more developed for daytime activities. Their globose eyes are on the sides of the head, which increases the visual field, allowing monocular and binocular vision. In general, the anatomical structure of the hummingbird eye is similar to that of other birds.

The two photoreceptors, the rods and cones, contain the visual pigments responsible for the absorption of light incident upon the retina. Rods are sensitive to colourless and dim light, whereas cones are receptive to colour vision. The three cone pigments are sensitive to red, green and blue light respectively (trichromatic colour vision). Behavioural studies indicate that, like pigeons and other birds, trochilids may have a fourth cone visual pigment that is sensitive to ultraviolet light between 325 and 360 nanometres. Since many flowers bear UV-specific colour patterns of changing sizes during their fertile phase, when high nectar rewards can be expected, hummingbirds may use these cues to locate food.

Among all birds, songbirds are considered to have the most highly specialized brains; their encephalization factor is 5.4 compared with the galliforms. In hummingbirds this figure is 2.5, still clearly smaller than in passerines. Though trochilids are intermediate, they can be considered as highly encephalized. The relatively high encephalization factor in hummingbirds can be interpreted in two ways: either the brain is relatively large with respect to the body, or the body is relatively small with respect to the brain. Probably the first assumption is more likely. Although hummingbirds are very small, it has been shown that even

The Rainbow-bearded Thornbill earns its name from a multicoloured strip of iridescence on the head of males. An emerald-green throat patch extends onto the chest as a fiery red strip and onto the crown as a yellow cap. In females, the extension of red is much reduced and the crown is largely rufous. This species frequents high altitudes in the Andes, where it feeds on the nectar of páramo plants, often perching rather than hovering, and it spends a large proportion of its time hunting insects on or close to the ground.

[*Chalcostigma herrani*
herrani,
Caldas, Colombia.
Photo: Luis Mazariegos]

an extremely small body size does not necessarily lead to an increased encephalization index. At the same time, the unique and complex behaviour of hummingbirds allows them to use their ecological food niche almost exclusively, demanding a highly specialized sensorimotor control (hovering) by the brain. It remains unknown which type of encephalization hummingbirds have undergone as there is no information on volumes of different structures of the brain. It has been suggested that this high encephalization factor is not only due to an enlargement of the forebrain but also in part to cerebellar and/or brain stem specializations.

Nectar preference tests show that foraging hummingbirds have control mechanisms at their disposal which allow them to regulate energy costs and benefits over time in order to build up the energy surplus necessary for their nocturnal resting phase. The quantitative proof leads to a clear evaluation of the energetic cost-benefit balances. They are ultimately determined by intercellular reactions whose catalysing function is temperature-dependent. For the optimal functioning of such chemical processes it is to an organism's advantage to maintain a relatively constant body temperature, within the constraints of its energy balance. This applies to hummingbirds as to most terrestrial endotherms.

The daily energy requirement of a 4-5 g hummingbird lies roughly in the range of 30-35 kJ, which amounts to five times the estimated basal metabolic rate. In order to meet their daily energetic needs hummingbirds have to consume the nectar of about 1000-2000 flowers each day. The estimated daily water intake with the nectar meals amounts to around 160% of their body mass. This significant water excess is eliminated in chronic diuresis, causing a salt-balance problem. Hummingbirds have solved this physiological constraint by having kidneys that contain a poorly developed renal core consisting largely of collecting ducts with only a few looped nephrons, or waste-extracting units. Hummingbirds thus do not concentrate their urine like other birds and mammals, but reclaim valuable salts thanks to a reduced osmotic concentration in the region of 15-24% of plasma concentration. Although 76-85% of the solutes is conserved each day, over 10% of body sodium and potassium is lost. These salts are normally replaced from trace amounts in floral nectars. It has been suggested that the evolution of nectar-feeding in trochilids led to their small body size. Therefore the constraints on kidney size to process this relatively large flow of excess water could only be handled by foregoing nephrons capable of producing concentrated urine (mammalian-type nephrons).

Trochilids are found between Alaska in the north and Tierra del Fuego in the south of the American supercontinent, occupying all types of habitat from sea-level to about 4500 m where flowering plants are available. Over 50% of all species occur in montane regions and are exposed to a daily temperature stress of more than 15°C. For physiologists it was therefore of particular interest to investigate the amount of heat production necessary to offset the difference between ambient and body temperature. If thermal conductance, a measure of physical characteristics influencing heat exchange, is high, then the bird is poorly insulated. One should expect trochilids to be poorly insulated because of their low body mass (in birds, thermal conductance increases exponentially by a factor of -0.5 with decreasing body mass), as well as by the relative small number of feathers covering their bodies. Nevertheless, hummingbirds have very high heat production per gram of body mass. Due to their low mass, their energy requirement for temperature regulation is much less than it is for larger animals. The main problem for small endotherms is to store sufficient energy to compensate for the expenditure involved in thermoregulation. In general, animals store energy in linear proportion to their body mass with a rate of increase of 1.0, but the rate of energy loss increases linearly by 0.75. The energetic problems experienced by very small animals result from the differences between these parameters. Thus, small endotherms like hummingbirds are under considerable time pressure: on the one hand they must meet their daily food requirements; and on the other, accumulate sufficient energy reserves to survive their nocturnal starvation. The following factors are therefore of decisive importance for extremely small hummingbirds: quality and accessibility of food; and mechanisms to reduce energy consump-

Many hummingbirds show patches of white that offset the brilliance of iridescent plumage. In particular, members of the genus *Heliangelus* are often characterized by the presence of white collars, as can be seen here in the male *Gorgeted Sunangel*. A hovering hummingbird has the highest oxygen demand of any vertebrate. At rest, the breathing rate is 300 times per minute, which rises when temperature increases or during flight to over 500 times per minute. In contrast, a resting human breathes roughly 14-18 times a minute and a pigeon around 30 times per minute.

[*Heliangelus strophanus*,
Mindo, Ecuador.
Photo: Luis Mazariegos]

The *Snowcap* is thus named because of the startling white crown feathers of males. This feature is very conspicuous against a background of dark iridescent plumage, and presumably performs a similar function to the iridescent crowns of other species which contrast with duller or differently coloured plumage. It lives in the lowland and foothill forests of Central America, where it forages at the small flowers of trees, such as *Warscewiczia*, shrubs, vines and epiphytes.

tion. In trochilids, these mechanisms are long periods of inactivity between daily meals and torpor.

During torpor, gaseous metabolism and body temperature are adjusted to the levels of ambient temperature and regulated to remain within the range of 18-20°C. In torpor, hummingbirds become lethargic and incapable of reacting in a coordinated way to external stimuli. Energy savings during this immobile state are considerable; up to 60% of the total energy accumulated for the nocturnal resting phase. During observations on Nearctic migratory hummingbirds an irregular occur-

rence of torpor was noted. Birds reacted only with torpor when energy levels fell below lower limits during the night. According to these studies, torpor is an energy-regulating mechanism which is triggered below a threshold value, equivalent to a physiological regulation pattern coming into force in extreme conditions. As reasons for the irregularity of torpor, physiologists cite the risks and energetic costs of the lethargic state. The risks involved would be the danger of predation while immobile, and insufficient residual energy for thermoregulation which could prevent awakening from torpor.

Recent research on Neotropical trochilids from a wide range of climatic zones and altitudes shows that in all species torpor occurs nocturnally. There are two distinct metabolic phases: during the night, metabolism is lowered by 80-90% of the daytime value for 2-6 hours, then, still in morning darkness, endogenously levels off in two different plateaux of regulation to normal activity. Torpor was noted in all ambient temperatures tested experimentally, from 5°C to 25°C, independent of taxon and body mass.

If a hummingbird was exposed to temperatures below 15°C the resulting body temperature was regulated to remain in the range of 18-20°C. This regulated reduction of metabolism and body temperature was accompanied by a drastic lowering of the heart rate to 50 beats per minute, and a reduction of the breathing rate by about 50% compared to activity levels. These results suggest that torpor in Neotropical hummingbirds occurs regularly as an energy-controlling system. Torpor duration and depth can vary depending on the size of the energy reserve accumulated during the previous day. It has been suggested by several ornithologists that torpor is a phylogenetically derived energy-saving mechanism in groups of endothermic organisms that occasionally (some pigeons and songbirds, mousebirds) or permanently (hummingbirds, shrews) live at the limit of their energetic existence. Torpor has an important additional function for these vertebrates because body temperature and metabolism are adjustable at any required energy level. The hypothesis that torpor is an acquired secondary character in the above vertebrates is supported by the fact that hummingbirds and shrews exhibit endothermy only at an age of at least one week.

Regular occurrence of torpor has not been observed in Nearctic hummingbirds. An explanation could be that these trochilids enjoy long daylight conditions of 14-16 hours in their northern summer quarters during which to feed, resulting in a positive energy balance. Changes in levels of metabolism and body temperature only occur when the lower energy balance threshold is crossed.

Habitat

Hummingbirds live in an extremely wide range of New World habitats. Some species like the helmetcrests (*Oxygogon*) in western Venezuela and Colombia, and the hillstars (*Oreotrochilus*) from Ecuador south to Chile, can be encountered at over 4000 m on the verge of Andean snowfields and glaciers, where in wind-sheltered and sun-exposed canyons a relatively species-rich community of bird and insect-pollinated alpine flora flourishes. These high-altitude trochilids forage among dense stands of year-round flowering Scrophulariaceae, Asteraceae (Compositae) and Gentianaceae, which provide nectar, their essential energetical

In many hummingbird species visual signals are not restricted to patches of bright colour, but include modified tail feathers or head feathers. The male Plovercrest has a long plume extending from its crown. The two forms of this species have different coloured crests: greenish in the race *lalandi* and bluish in *loddigesia*.

[*Stephanoxis lalandi lalandi*.

VIREO]

At around 4000 m, beside the glaciers and snowfields of the Andean cordilleras, night temperatures fall well below zero and blizzards are regular. The fact that the Bearded Helmetcrest and members of *Oreotrochilus* are amongst the few birds that can survive there is testament to the resilience and adaptability of the family. Only when snow cover is comprehensive do they descend a few hundred metres to the sparsely vegetated upper páramo, returning to higher altitudes when conditions improve. As a result of their adaptation to this extreme habitat, they enjoy reductions in both predation and competition for resources, since potential predators and competitors are scarce.

The Frilled Coquette is an inhabitant of forests and secondary growth in the lowlands of Brazil and Bolivia. Its shining throat is enhanced by a suite of secondary signals, including cheek tufts and a crest which can be raised during display. Coquettes are often "territory parasites", feeding at profitable patches defended by larger, more aggressive species. They pursue this strategy surreptitiously by frequenting inconspicuous locations, avoiding territory owners and acquiring resources without physically competing for ownership of the patch.

[*Lophornis magnificus*,

fuel, and attract the insects that supplement their diet. Nocturnal frosts, occasional snowstorms, and daily temperatures of a few degrees above zero are the environmental conditions in these Andean regions. Helmetcrests and hillstars rarely leave this alpine habitat, except for periods of longer snow cover. Then they shift to the upper *páramo*, an open grass-dominated vegetation with scattered stands of small trees and shrubs, only a few hundred metres below their native habitats. Often they leave the *páramo* plateaux again after a few hours and return to the rocky heights when weather conditions are favourable again. During frosty nights, trochilids of alpine Andean regions seek shelter in caves, commonly found below the snowfields of volcanoes, or under overhanging vegetation on the steep slopes above mountain streams or ravines. The members of these two hummingbird genera have evolved in such a way that the only habitats they are able to occupy on a regular basis are the extreme environments of the high Andes. Here they are physiologically well adapted, they reproduce successfully without facing strong competition for nesting sites and food from other trochilids, and, equally importantly, they are not exposed to predation.

At slightly lower elevations, between 3000 and 3800 m, a grassland zone forms the characteristic vegetation. Whereas the high Andes of Venezuela, Colombia and Ecuador are cool and damp, the Altiplano of Peru and Bolivia is characterized by being cool and dry.

Penetrating drizzle, sometimes turning into snow, and a constant dense fog cover, leaving everything dripping wet, is the characteristic weather of the Andean *páramo*, known from Ecuador north to western Venezuela. Although grass tufts carpet the ground at these altitudes, numerous taller herbaceous plants form the typical landscape, like the man-sized giant *Espeletia* (Asteraceae), locally called *frailejones*, with typical rosette-like broad whitish hairy leaves, and terrestrial bromeliads of the genus *Puya* (Bromeliaceae), with huge cone-shaped inflorescences consisting of hundreds of single flowers. Besides these more obvious typical *páramo* plants, a large number of other herbaceous flowers and woody plants, all several metres high, belonging to many different families, including Rosaceae, Myrtaceae, Ericaceae and Melastomataceae, often occur in wind-sheltered ravines. In this border zone between small patches of forest thickets and open *páramo*, members of over half a dozen trochilid

taxa occur all year round, albeit at varying densities, namely species of the genera *Aglaeactis*, *Chalcostigma*, *Metallura*, *Ramphomicron*, *Lafresnaya*, *Eriocnemis*, and sometimes *Chaetocercus*. Some species like the Purple-backed Thornbill are stragglers, or, in the case of the Shining Sunbeam (*Aglaeactis cupripennis*), local migrants in parts of their range. During the major flowering period from the end of June to August, many more hummingbirds from lower elevations temporarily visit the *páramo* due to the superabundant nectar supply in the dense stands of angiosperms, plants which are in turn dependent on trochilids for pollination. Then large numbers of Sparkling Violet-ears from the lower Andean valleys, and occasionally, during warmer sunny days, even Green Hermits (*Phaethornis guy*) from the upper tropical rainforest may be encountered on the *páramo*. However, these species disappear in the afternoons, obviously returning to lower elevations again.

The mostly dry and windy *puna* zone of the Peruvian and Bolivian Andes is less favourable for hummingbirds than the northern wet *páramo* at similar altitudes. In the *puna*, trochilids are much more confined to edges of *Polylepis*-*Gynoxys* woods and to sheltered gulleys with bushy vegetation, than to open grassland. The Giant Hummingbird and the Andean Hillstar (*Oreotrochilus estella*) occur regularly in the open grasslands of the southern high Andes mainly during the flowering period of the arborescent puya *Puya raimondii*. A typical open *puna* species, the Olivaceous Thornbill (*Chalcostigma olivaceum*), frequently perches on grass tussocks from where it sallies forth for flying insects. However, most of the hummingbirds at this altitude are found around the edges of *Polylepis* forest and stands of composite shrubs, Scrophulariaceae (*Castilleja*), and cacti (*Opuntia*) flowers, which supply energy-rich nectar, the prerequisite for remaining sedentary at these climatically hostile altitudes.

At 3500 m, the *páramo* and *puna* are sharply replaced by shrubs and trees of the upper Andean forest. Where the two habitats merge, the hummingbird community comprises almost a dozen sympatric species foraging for nectar from a highly diverse ornithophilous angiosperm assemblage, comprising many taxa of vines, shrubs and woody plants such as *Bomarea*, *Fuchsia*, *Lobelia*, *Passiflora*, *Brachyotum*, *Befaria* or *Datura*, with brightly red- or orange-coloured tubular flowers, a major visual

The White-tailed Starfrontlet, endemic to the Santa Marta Mountains of northern Colombia, shows remarkable contrast between dark body plumage and a white tail, a contrast particularly visible in the gloomy understorey of the forests it frequents. As a general rule, hummingbirds drink their body mass of nectar in several hours, thus supplying the necessary energy for growth and maintenance of body temperature at 40°-42°C. As hummingbirds have the highest mass-specific basal metabolic rate of all birds, their digestive system is adapted to maximize the speed with which nutrients are metabolized and absorbed.

[*Coeligena phalerata*, Santa Marta, Colombia. Photo: Luis Mazariegos]

cue for their minute avian visitors. From Venezuela to the Yungas of Bolivia this life-zone forms the upper distribution limit of the Sword-billed Hummingbird, a little-studied specialist of long-tubed pendent flowers, with the longest bill of all trochilids, up to 12 cm long. Another large hummingbird occupying the same habitat is the Great Sapphirewing (*Pterophanes cyanopterus*), as well as other closely related long-billed allies from the inca and starfrontlet group (*Coeligena*), together with pufflegs (*Eriocnemis*) and sunangels (*Helianthus*). Whereas the *Coeligena* assemblage occupies forest edge and forest interior habitats from low-growing shrubs to the subcanopy of trees, the pufflegs and sunangels of that altitude are more restricted to the buffer zone of shrubs between the semi-open sub-*páramo* and the upper Andean forest belt.

The richest altitudinal zone in terms of hummingbird species is the transitional zone between the Andean forest and the adjacent

lower submontane forest, roughly between 2500 m and 1800 m. Here the daily temperature is fairly constant, ranging around 12-16°C. Daily cloud cover, especially in the afternoon, brings the moisture that sustains a rich plant life of ferns, shrubs, trees, vines and especially epiphytes, like orchids, bromeliads, gesneriads and ericads. As diurnal endotherms, trochilids are the most successful organisms serving the cloudforest plants as pollen vectors. At these altitudes, heterothermic insect pollinators are dependent on favourable temperature and weather conditions, which limits their flight activity to a few, often unpredictable daytime hours.

Although there is some flowering seasonality among ornithophilous plants of different families like Ericaceae and Rubiaceae, this Andean life-zone between 12° north and south of the equator provides abundant nectar all year round, allowing the co-existence of over a dozen hummingbird species. The cloudforest trochilid community comprises a concentration of very small to medium-sized and large species from about 3 to 12 g, with diverse bill shapes and sizes. If we list body size and bill shape of typical members of the Ecuadorian cloudforest trochilid assemblage, an impressive picture can be gained of the variety of niche exploitation possibilities: the Booted Racquet-tail has a tiny body, and the bill short and straight; the Purple-bibbed Whitetip (*Urosticte benjamini*), small, and straight; Speckled Hummingbird (*Adelomyia melanogenys*), medium-sized, and short; Hoary Puffleg (*Haplophastura lugens*), small, and short; Wedge-billed Hummingbird (*Agastis geoffroyi*), small, and short and conical; Andean Emerald (*Agyrtia franciae*), medium-sized, and straight; Green-fronted Lancebill (*Doryfera ludovicianae*), medium-sized, and long and straight; Violet-tailed Sylph (*Agelaiocercus coelestis*) medium-sized, and short and straight; Tawny-bellied Hermit (*Phaethornis symrathus*), large, and long and decurved; Brown Inca (*Coeligena wilsoni*), large, and long and straight; Buff-tailed Coronet (*Boissonneaua flavescens*), large, and long and straight; White-tailed Hillstar (*Urochroa bougueri*), very large, and short and straight; Fawn-breasted Brilliant (*Heliodoxa rubinoides*), large, and short and straight; and Brown Violet-ear (*Colibri delphinae*), medium-sized, and short and straight. Alongside these core species another 10 to 15 hummingbird taxa may be found in the cloudforest during the peak of the flowering season, attracted by the nectar-rich ericad shrubs and *Inga* trees. These trochilids comprise various lowland spe-

The tiny Tyrian Metaltail is an inhabitant of the magnificent Andean highlands from Venezuela to Bolivia, occupying both sides of the ecotone where páramo and elfin-forest meet. It is commonest above this rather abrupt divide, frequenting moist páramo grasslands that are often smothered in fog and drizzle. With its tiny bill it sips nectar from the inflorescences of terrestrial bromeliads and the innumerable flowering shrubs that grow in this zone.

[*Metallura tyrianthina* tyrianthina, Cauca, Colombia. Photo: Luis Mazariegos]

cies like the minute Green Thorntail (*Discosura conversii*) and the much larger White-necked Jacobin (*Florisuga mellivora*), as well as members of high-Andean guilds such as the large Sparkling Violet-ear and the tiny White-bellied Woodstar.

The tropical lowland forests of South America, in stark contrast, harbour a much impoverished hummingbird community. Dominant species of this life-zone mostly belong to the subfamily Phaethornithinae (*Androdon*, *Eutoxeres*, *Glaucis*, *Threnetes* and *Phaethornis*), whereas trochilines are normally represented by the genera *Amazilia*, *Polyerata* and *Agyrtria*, and by *Hylocharis*. The first of these two groups is represented west of the Andes by the Rufous-tailed (*Amazilia tzacatl*) and Purple-chested Hummingbirds (*Polyerata rosenbergi*), whereas east of the Andes are found the Versicolored (*Agyrtria versicolor*), Glittering-throated and Plain-bellied Emeralds (*Agyrtria leucogaster*). Similarly, in the second group, the Blue-headed Sapphire and Blue-throated Goldentail occur west of the Andes, whereas the Rufous-throated (*Hylocharis sapphirina*) and White-chinned Sapphires are found mainly east of the Andes.

Cis- and trans-Andean hummingbird taxa often constitute allopecies of a superspecies with almost identical ecological requirements. A fine example is provided by the two tropical lowland species of the genus *Heliothryx*, separated in their distribution by the Andes. Along the Pacific coast, the Purple-crowned Fairy (*Heliothryx barroti*) is the sole member of the genus, replaced in the Amazon by its sister species the Black-eared Fairy (*Heliothryx aurita*); these two congeners are very similar in their morphological characteristics. Whereas many lowland trochilids forage at certain foliage heights, the fairies belong to those few hummingbird species making use of the complete vertical stratum, sallying during their search for nectar and arthropods several times a day from near the ground to the highest tree tops.

There are several other lowland trochilids like *Florisuga*, *Anthracothorax*, *Topaza* and *Campylopterus*, but many of these taxa are of local distribution; or require specific habitats within the lowlands such as semi-deciduous forest or savannas; occupy a wide range of altitudinal vegetation zones; seasonally disperse to lower altitudes; or are migrants.

Tropical mangroves play a negligible role in the distribution of trochilids. Only one species, the Mangrove Hummingbird (*Polyerata boucardi*), from Costa Rica, is restricted to these coastal lowland habitats. Others like the Glittering-throated Emerald may invade this vegetation during breeding, but are not found there all year round.

In a few cases it is evident that certain taxa are ecologically replaced by others of similar body mass and morphological features. The best example is the long-billed hermit assemblage.

Conspicuous tails are taken to extremes in hummingbirds such as the male Red-tailed Comet, in which they are not only bright but highly elongated. In females the tail is less spectacular, being shorter, duller and less deeply forked. This species is fairly common throughout its range in Bolivia, Argentina and Brazil, where individuals are commonly glimpsed as a streak of red speeding between feeding patches on open slopes.

[*Sappho sparganura*
sparganura.
Photo: François Gohier/
Ardea]

Many hummingbirds possess very bright tails.

The Golden-tailed Sapphire is one such species, males exhibiting brilliant bronzy-copper rectrices, while females are considerably duller.

It is not clear what function bright tails perform, but they are possibly important in courtship when the males assemble at leks consisting of five to ten individuals. This species occurs mainly in primary and secondary forest at lower altitudes, occasionally defending territories in the absence of more aggressive species. The solitary and non-territorial females, meanwhile, feed at dispersed sites in forest.

[*Chrysuronia oenone*
oenone.
Meta, Colombia.
Photo: Luis Mazariegos]

Above 2500 m they are gradually replaced by the morphologically similar long-billed species-group of the incas and starthroats (*Coeligena*). At altitudes where members of both taxa are sympatric, they compete for the same flowers, but deal with this situation by a vertical niche segregation. Hermits remain closer to the ground when foraging for nectar, while the incas and starthroats visit flowers from the middle storey to sub-canopy level.

Hummingbirds occur in many other life-zones including: arid scrub, home of the Lucifer Hummingbird (*Calothorax lucifer*) and the Peruvian Sheartail (*Thaumastura cora*); desert oases, the Oasis Hummingbird (*Rhodopis vesper*); Nearctic pine forests, with many North American species including the Broad-tailed and Magnificent Hummingbirds; and on remote islands in the Caribbean (*Trochilus*, *Chlorostilbon*, *Eulampis*, *Mango*, *Orthorhyncus*) and on the Juan Fernández Islands off Chile, where the Green-backed (*Sephaniodes sephaniodes*) and Juan Fernandez Firecrowns are found. However, many of these habitats are occupied only sporadically for a short period or seasonally during the breeding period, when foodplants are in flower, often providing superabundant nectar. Birds leave these regions again when conditions become unfavourable. Many of the North American trochilids then disappear and migrate to their Central American winter quarters. The same is true for the Green-backed Firecrown, from Chile, which leaves its southernmost summer range on Tierra del Fuego to migrate northwards to western Chile and Argentina. On larger islands, hummingbirds show altitudinal migration or disperse to different lowland habitats.

Where several species of hummingbird co-exist in the same habitat they would be expected to show different body masses and/or bill lengths to reduce interspecific foraging competition among flower-visitors. And indeed this hypothesis is particularly well supported by the example of the trochilids of the Antilles. Two species, differing in their body mass by a factor of around 2, occur on most of the islands. However, where both species have the same body mass, as is the case of the Antillean (*Anthracothorax dominicus*) and Green Mangos (*Anthracothorax viridis*)

on Puerto Rico, they exclude each other by preferring different habitats. This simple ecological separation is confirmed by looking at the corolla length and nectar production rate of the corresponding food plants. There are two categories: first, corollas 17-20 mm in length, with a nectar secretion rate of 1-2 microlitres of saccharose per day, and with flowers that are visited by the smaller short-billed species of hummingbird; and, second, corollas 30-38 mm in length, with a nectar secretion rate of 4-27 microlitres of saccharose per day, and with flowers that are visited by the larger long-billed species. In tropical regions with species-rich hummingbird communities we find not only differing body masses and morphological characteristics but also species-specific foraging strategies.

Trochilid habitat requirements are still poorly understood. Many species exhibit a remarkable adaptability, easily adjusting to man-made habitat changes, or even expanding their ranges if food conditions are favourable, as in Anna's Hummingbird (*Calypte anna*). Others rapidly decline in numbers and face extinction following environmental disturbance, for instance the Hook-billed Hermit (*Glaucis dohrnii*). In addition to habitat changes, there are cases of competition for food, either from congeners, as with the two *Sephaniodes* species in the Juan Fernández Islands, or not, as in the case of the Chilean Woodstar (*Myrtis yarrellii*) with the larger Oasis Hummingbird; such cases must be thoroughly analysed in the future in order to achieve a better understanding of hummingbird community structure and change, essential factors for any successful conservation programme.

General Habits

Physiological adaptations for nectar feeding, and energy regulation patterns resulting from limiting temporal and environmental conditions are fundamental factors for understanding the general habits of trochilids. The utilization of energy-rich nectars most likely fostered strong individual competition for this food source, favouring the evolution of specific maintenance and survival strategies. As a general consequence, males and females of almost all hummingbird species so far studied live solitarily, often aggressively defending nectar sources in the form of flowering shrubs and trees against any potential food competitor. The sexes are polygamous and associate only briefly to fertilize the eggs.

In general, the males of species with bright iridescent colours establish feeding territories at flowering bushes which allow them to cover their daily energy needs. In order to defend their nectar resources they often perch high on nearby exposed branches. These

In some species, the tail feathers themselves are not only bright but also modified in design. The male Red-billed Streamertail provides a perfect example of this phenomenon, one pair of glossy purple rectrices being greatly elongated into a lyre-like shape. This species is restricted to Jamaica where it inhabits virtually all habitats from sea-level up to elfin forest, and densities of up to 12 pairs/km² have been reported in the Blue Mountains. It apparently prefers disturbed or man-modified habitats, being common in parks and suburban areas where it often extracts nectar through the holes made by Bananaquits (*Coereba flaveola*). In forests it also attends fresh Yellow-bellied Sapsucker (*Sphyrapicus varius*) drillings in tree trunks.

[*Trochilus polytmus*, near Kingston, Jamaica. Photo: Robert Tyrrell]

The racquet-shaped appendages of the male Booted Racquet-tail presumably present a slight aerodynamic inconvenience to their tiny bearer. It seems more than likely that modified tail appendages in hummingbirds are analogous to the sexually selected tail of peafowl (*Pavo*): in other words, that their evolution has been driven by female preferences, and that these in turn are associated with the information conveyed by the ability of males to produce these ornaments and to carry the associated handicap.

Of all hummingbirds,
the most bizarre tail
design surely belongs to
the Marvellous Spatuletail.

This species is highly
unusual in that it has only
four tail feathers, unlike
the ten of all other
members of the family.
Two of these form long
curled shafts that cross
over behind the body and
carry broad spatules at
their tips. A small
population of this species
inhabits forest edge,
second growth, montane
scrub and impenetrable
Rubus thickets admixed
with *Alnus* trees on the
east bank of the Rio
Utcubamba, northern
Peru. These habitats are
being rapidly eradicated
by the spread of
agriculture and the
demand for fuel, and this
species is thus red-listed
as Vulnerable.

[*Loddigesia mirabilis*.

serve as vantage points from which predators can be detected with ease or from which the area can be defended against possible intruders, including females, by vocal warning signals and agonistic flights. Often the territory holder first empties the nectar from peripheral flowers to remove or reduce the feeding reward for newly arriving competitors. Trespassers ignoring the threat calls of the territory owner are robustly attacked in flight, sometimes resulting in direct physical combat. An airborne fighting pair may then be locked in strong claw grips, tumbling to the ground like a falling stone. These fights are rarely harmful to the birds but occasionally small featherless areas can be seen on the upperparts as a result of such aggressive encounters.

Male Purple-throated Caribs react differently to territorial intruders and food competitors during the reproductive period. All but their mates are aggressively chased out of the defended feeding area. Incoming females, however, are guarded and allowed to feed prior to mating. A similar function of the feeding territory has been observed in the tiny dimorphic Green Thorntail by K. L. Schuchmann. From December to March, during the breeding period of the species, *Inga* trees begin to flower in south-western Colombia. Then the long-tailed males establish and defend feeding territories in these forest giants. Short-tailed females entering these feeding grounds are allowed to feed on the nectar-rich brush-like white flowers of the trees; both sexes are nectar thieves, hardly contributing to the cross pollination of *Inga* trees. Frequently, males display to individual females and copulate with them while they are in their territory. Male Green Thorntails aggressively attack all possible territory intruders, even much larger trespassing birds like the numerous Tropical Kingbirds (*Tyrannus melancholicus*) gathered around flowering *Inga* trees. Besides females of the Green Thorntail, a small diurnal moth, the white-banded sphinxlet (*Aellopos titan*), similar in size, appearance and flight behaviour to the white-rumped hummingbird, visits the guarded territories. Being almost perfect female mimics to male hummingbirds, they are obviously considered as potential mates, indicated by the displays directed at them. However, because of their fast and unpredictable flights within the densely packed *Inga* flowers, male Green Thorntails quickly lose interest in these female mimics but still continue with their mate-defence behaviour. Hummingbird males direct their agonistic flight manoeuvres especially at Tropical Kingbirds,

which prey on the white-banded sphinxlet. When male hummingbirds were excluded from a flowering *Inga*, predation rate on the moths was over 80%, and individual moths spent only 1-3 seconds at each flower. When such an *Inga* tree was guarded by a Green Thorntail, male sphinxlet predation by kingbirds declined to 20% and most moths spent 4-6 seconds feeding at each flower visited. In the latter case, *Inga* seed production was significantly higher than in a territory without a hummingbird guard. This mimicry relationship between two different animals, a moth and a hummingbird, is an instructive example of the complex inter-related webs of adaptation in the tropics.

Territories are still defended for a while even when the nectar supply diminishes through time. However, as indicated by the behaviour of Anna's Hummingbird in the western USA, when food becomes scarce, song and gorget display directed at food competitors are the primary form of agonistic behaviour, while chases and aerial displays are less frequently observed; it seems most likely that this is a behavioural adaptation to save energy.

Females of a few hummingbird species may hold temporally and spatially limited territories around localized feeding sites during and after the reproductive period. Studies by J. Dorst, K. B. Armitage and M. L. Cody looked at females defending nest surroundings and birds on migration defending a small area at a locally plentiful food source. However, the maintenance of long-term feeding territories is known only for the Fiery-throated Hummingbird (*Panterpe insignis*), a brightly coloured monomorphic species of southern Central America. This type of territoriality reflects the temporal and spatial decline of nectar resources in conjunction with the resident status of the birds. L. L. Wolf, who has studied female territorial behaviour of this species in Costa Rica, suggests that territoriality in trochilids is accompanied by strong selection for sexual monomorphism in plumage coloration, as being advantageous in aggressive encounters, and for sexual similarity in bill length as advantageous for efficient utilization of limited food resources.

Many species in tropical Central and South America do not establish feeding territories but are trap-line feeders on flowers often too scattered to be defended. But between territoriality and trap-line behaviour many more intermediate feeding strategies can be found, depending on flower dispersion, morphology and nectar reward (see Food and Feeding).

The Emerald-bellied Puffleg, along with most other members of its genus, is distinctive in that both sexes sport conspicuous white tufts at the base of the legs. This species is patchily distributed in humid montane forest in the northern Andes, generally feeding on nectar and taking insects only occasionally. As a result of competition for the energy-rich resource, it is often solitary and aggressively territorial, defending flowering shrubs and trees.

[*Eriocnemis alinae alinae*, Putumayo, Colombia.
Photo: Luis Mazariegos]

Despite being under extreme pressure to gather energy quickly, and having developed many obvious behavioural traits for doing so, hummingbirds spend over 70% of their daily activity phase perched, apparently doing little else besides singing, self-preening and sunbathing. In an experimental study on North American hummingbirds, M. A. Hixon and co-workers discovered that most individuals observed fed at around four-minute intervals. This corresponds well with the findings by J. M. Diamond and members of his research group who demonstrated that laboratory-kept trochilids required four minutes to empty their nectar meal from the crop into the intestine; crop-emptying is in turn limited by the ability of the intestine to absorb the nutrients contained in the food (see Morphological Aspects). Because of this digestive bottleneck, hummingbirds are unable to absorb sugar any faster.

Hummingbirds bathe several times a day. Some sit in shallow water and splash like sparrows, others cling to rocks beside waterfalls gathering moisture and spray from above, vibrating their wings and ruffling their body feathers. Hermits and many trochilids hover just above gently flowing forest streams, then abruptly drop into the water, sometimes almost completely submerging the body. These dives are sometimes repeated over several minutes. In addition to waterfalls, other sites also accepted as bathing facilities by several species include forest pools, quiet streams, and large banana and *Heliconia* leaves that accumulate water or dew. Quite often during gentle rains individuals perch on exposed twigs with spread and vibrating wings and fanned tail feathers obviously enjoying their bathing activities.

Sometimes between each bath, or after several dives, birds return to a nearby perch, shake the water out of their body feathers and begin to preen their plumage. Hummingbirds spend extended periods self-preening. Most species use the bill for oiling, cleaning and arranging their feathers. Normally the lower underparts, primaries and secondaries, wing-coverts, the lower upperparts and the rectrices are all preened with the bill. The region of the head and throat is preened using the claws, by lifting the foot up and over the wing. The Sword-bill Hummingbird, however, preens most of the body and tail feathers with its elongated claws, including even parts of the secondaries and primaries.

Hummingbirds do not show flocking behaviour. Individual social contacts are rare but occasionally do occur around supra-

bundant nectar sources and at cave roosting sites, notably in the hillstars (*Oreotrochilus*). Nest aggregations within a few metres are known for the cave-breeding Ecuadorian Hillstar (*Oreotrochilus chimborazo*) and within a radius of 20-30 m for Costa's Hummingbird (*Calypte costae*), the Bahama Woodstar (*Calliphlox evelynae*), the Rufous-tailed Hummingbird and the Crimson Topaz (*Topaza pella*).

Hummingbirds are well known for their constant interest in investigating all kinds of natural and even artificial items, especially when brightly coloured. Many curious stories exist of trochilids examining red plastic markers or even approaching humans wearing brightly coloured shirts or caps. These close inspections by hummingbirds may be explained by their constant need to find nectar sources to satisfy their energetic needs.

Hummingbird foraging behaviour is determined to a large extent by individual perception and memory capability. Field and laboratory studies by G. H. Pyke, conducted with North American Broad-tailed and Rufous Hummingbirds, suggest that these hummingbirds may at least perceive and remember the number of flowers available on an inflorescence, the number of flowers already probed on the inflorescence and the amount of nectar obtained at the present flower.

Many hummingbirds are already active before dawn and late after sunset. A remarkable example is provided by the high-altitude incas and starfrontlets (*Coeligena*), which visit flowers in the early morning hours when it is still dark. Other species still continue to forage for nectar in the evening twilight before disappearing to their roosts. Although hummingbirds are not nocturnal, the night vision of some species seems to be excellent.

Ornithologists have discovered trochilids at their roosting sites on only a few occasions. Their sleeping places are sometimes well protected by leaves, as in the Rufous-tailed Hummingbird, whereas the Long-billed Starthroat (*Heliomaster longirostris*) roosts on the thin exposed twigs of tree tops. The sleeping position of perching trochilids is strikingly similar in all species observed: with both feet on the perch, head exposed, neck retracted, and the bill pointed forwards and upwards. The tiny Wire-crested Thorntail (*Discosura popelairii*) maintains a similar upright sleeping position but the rectrices are stretched forward underneath the bird's body, possibly to achieve a more effective posture for maintaining balance. By contrast, songbirds

on their roosting sites cover the backward-turned head with the shoulder feathers and often perch on one foot.

Hummingbirds are threatened by only a few predators among vertebrates. Camouflaged snakes on *Heliconia* flowers prey on them when they are foraging for nectar, and will also attack them when the birds are brooding. Forest-falcons (*Micrastur*) occasionally capture hermits at their lek sites, and pygmy-owls (*Glaucidium*) may attack them at dawn when the hummingbirds are visiting flowers. Nest robbers like jays (*Corvidae*), toucans

(*Ramphastidae*) and possibly some bats, however, seem to be the major predators, although it should be stressed that this information has been generated only through occasional observations, so the impact of predation on hummingbird populations is almost completely unknown. Whenever a potential enemy is sighted by a hummingbird it is directly approached by rapid diving attacks accompanied by a series of high-pitched warning calls. These alarm signals regularly attract other bird species, which join in the aggressive flight encounters supported by continuous

Hummingbirds undergo a single protracted annual moult, which commences soon after the breeding season. Initially, primary moult proceeds descendantly, from innermost outwards, while the secondary moult proceeds in centripetal order, as shown by this male Antillean Crested Hummingbird. This familiar sequence is reversed for the last two primaries in a unique but necessary inversion that helps maintain stability in hovering flight. Rectrix renewal also differs from most birds in that the outer tail feathers are moulted in advance of inner ones. Body moult commences with the shedding of primaries and continues until their replacement is completed. The moult of iridescent feathers, however, tends to take place last of all, often several weeks after the primaries have been fully renewed; this presumably ensures that plumage important for signals is in the best possible condition for the breeding season.

Le Lamentin, Martinique.
Photo: R. Tyrrell]

Different species of hummingbird occupy widely divergent ecological niches, especially in the tropics where specialization is promoted by high resource levels and intense competition. Temperate species, such as the Green-backed Firecrown, compete in species-poor hummingbird communities in search of scarcer resources, a system which favours generalism. Partly for this reason, the species can be found in a wide variety of habitats including forests, deserts, mountains and open country. It visits southern Patagonia and Tierra del Fuego in the local summer, migrating northward to northern Chile and Argentina during the winter.

[*Sephanoides sephanioides*, Los Alerces National Park, southern Chile. Photo: Günter Ziesler]

mobbing noises. Threat behaviour by flight attacks is exhibited especially by female hummingbirds against intruders near their nesting sites, even if they are not potential predators.

Some typical habits are known for closely related groups, indicating that specific forms of behaviour may be of importance for the reconstruction of phylogenetic traits. All hermits (Phaethornithinae) exhibit constant tail-wagging behaviour when perching, and the courtship of all species studied so far features fanned rectrices and wide-open bills displaying the yellow, orange or red interior base of the lower mandible in the Gape Display. These habits are not known for any of the non-hermit species. In the Andean trochiline assemblage (*Chalcostigma*, *Metallura*, *Eriocnemis*, *Haplophadja*, *Urostroke*, *Oreocnemis*, *Aglaiocnemis*, *Boissonneaua* and others) a typical habit is to keep the wings stretched out for a second or so after landing on a perch.

General habits, and their associated behavioural background, are poorly studied in trochilids. The same is true of hummingbird vocalizations and song-learning capacities, research fields which could lead to a holistic approach to understanding the evolution of life-history traits in one of the most species-rich Neotropical avian families.

Voice

In their usually cluttered habitats, hummingbirds are often heard before they are seen. Unmelodious, high-pitched monosyllabic chirps and whistles are normally the sounds perceived during initial encounters with these birds. Their calls, often lasting less than half a second, are generally uttered by both males and females between feeding probes or from exposed perches in shrubs or tree tops, and indicate territorial birds occupying nectar-rich food sources. Chase calls, a series of aggressive rapid chattering sounds known from several species, are heard from individuals defending a feeding territory. These loud vocal signals, employed by either sex, are species-specific and an important feature for field identification.

Many trochilid species employ an advertising song of simple syllabic structure and short duration. It consists mostly of monosyllabic elements, comprising a very brief syllable of about one second and a slightly longer one lasting up to two seconds. This

acoustic advertising is repeated continuously for several minutes, sometimes for up to half an hour. Most of the songs known from hummingbirds are of high frequency, interrupted by guttural or shrill sounds, often rather unpleasant to the human ear.

Due to the minute size of trochilids many of their complex guttural vocalizations can be detected by the human ear only when at a very short distance from the singing bird. Certain elements, such as in the song of the Black Jacobin (*Florisuga fusca*), may

Hummingbirds often scratch the head and upper body by lifting the foot up and over the wing. In many species, for example the Hairy Hermit, the length of the bill precludes its use in preening these portions of the body and thus the claws may be employed for certain maintenance activities. This species is unique in that pair-bonds have been described wherein males defend females in their territories from the attentions of rival conspecifics.

[*Glaucis hirsuta hirsuta*, Burro Burro River, Guyana. Photo: Doug Wechsler/VIREO]

Hummingbirds spend a considerable amount of time preening, especially immediately after bathing.

Most species use their bills for arranging, oiling and cleaning their feathers, reaching as far up the body as bill length will allow. This Red-tailed Comet is preening the

mantle feathers, or perhaps collecting oil from the oil gland. The remiges and rectrices are often arranged with the bill, as illustrated by this Violet-headed Hummingbird.

even be completely inaudible to us, since they reach ultra-sound levels. Only rarely can certain elements of a hummingbird's vocal repertoire carry over a distance of a hundred metres. Among these few exceptions are the high whistles of the Brazilian forest-dwelling Saw-billed Hermit (*Ramphodon naevius*).

Some species employ a longer and more melodious song. The Wine-throated Hummingbird (*Atthis ellioti*) and the Vervain Hummingbird (*Mellisuga minima*) each have an elaborate musical whistle lasting over half a minute. For its attractive warbling song the Wedge-tailed Sabrewing (*Campylopterus curvipennis*) of Central America is locally called "nightingale". Among the members of the Phaethornithinae, the song of barthroats (*Threnetes*) is also known for its short warbling tunes interspersed with squeaky chirping notes. It is mainly heard during the rainy period, though often ceasing prior to the end of the wet season. Members of the hermit genus *Phaethornis*, for instance the Little Hermit (*Phaethornis longuemareus*) and the Eastern Long-tailed Hermit, perform their songs almost all year round, except during the peak of the dry season when nectar availability is drastically reduced, whereas the Blue-throated Goldentail of Central America and the Violet-headed Hummingbird (*Klais guimeti*), members of the Trochilinae, can be heard only during the dry season, falling silent at the onset of the wet period. The Rufous-tailed Hummingbird sings mainly during the short time span from dawn to sunrise.

Some hermit species of the genus *Phaethornis* and some trochilines, such as the violet-ears (*Colibri*), belong to the most persistent daytime singers of all hummingbirds, producing their vocal repertoire tirelessly from early morning to sundown. They are only silent during the months of body moult, when singing ceases in most of the hummingbird species studied.

Male Sparkling Violet-ears devote up to 70% of their daily activity to the song display. This time- and energy-demanding behaviour may have led to a loose co-operation between some conspecific male neighbours. Individuals can then perform activities other than singing, such as preening, sun-bathing or feeding, while resting assured that the singing activity is maintained. Females receptive to copulation can thus easily locate mates at almost any time of the day. Singing activity is generally associated with reproduction and is thus, as in many other birds, a reliable indication of the nesting period of each species.

Several taxa from both hummingbird subfamilies establish singing assemblies at traditional mating sites, the so-called leks. These leks may comprise two or three, sometimes up to ten, and rarely, as in the Green Hermit on Trinidad, over 20 singing conspecific males. At these advertising sites, males occupy song perches from near the ground, as in the Little Hermit, to the subcanopy level, as in the Great-billed Hermit (*Phaethornis malaris*). Females visit singing males at these leks. It would seem that the rate of singing is important in female mate choice, since males spontaneously increase their own song rate when females enter a lek site. As in other lekking birds, trochilid leks are normally of small neighbourhood size and somewhat dispersed. Since large assemblies do rarely occur, it has been suggested that a threshold of neighbourhood size decreases the probability of song interference. Furthermore, in larger groups some males would become central rather than edge birds, with less opportunity to copulate with females, which often mate with the first male they encounter. Copulation can take place on song perches or nearby.

Besides the squeaky, high-pitched persistent advertising songs performed by many lekking males (*Phaethornis*, *Amazilia*, *Polyerata*), a low-volume warbling subsong of fledglings and adults of both sexes is typical for many trochilid species. Very often aerial displays are accompanied by a specific vocal repertoire and by mechanical sounds, such as tail-feather and wing noises in *Selasphorus*, that are not employed at other times.

Vocal duetting has been reported in only one species, the Hairy Hermit (*Glaucis hirsuta*), where the female continues the whistling notes of the male with an answering guttural phrase. L. F. Baptista and K. L. Schuchmann documented song-sharing between neighbours in the North American Anna's Hummingbird, and demonstrated by experiments that song parameters such as syllabic structure, rhythm, frequency-repetition index, and syntax are the result of acquisition by vocal mimicry in this species.

Anna's Hummingbirds on Guadalupe Island, off western Mexico, produce songs distinctly different from those in mainland California. A hybrid male Anna's x Allen Hummingbird (*Selasphorus sasin*) sang an aberrant abbreviated song. In the following year the hybrid's territory was occupied by a male Anna's Hummingbird that sang a song similar to that of the hybrid. It was suggested by S. Wells and L. F. Baptista that the

Hummingbirds bathe several times a day. They often perform this ritual by sitting in shallow water and splashing about like many other bird species, but they will also perch adjacent to splashing water, and, like this Green Violet-ear, flap the wings and ruffle the feathers in the spray. In addition, hermits and some trochilines bathe by hovering just above calm water and plunge-diving briefly to wet their plumage. During rain, individual hummingbirds can occasionally be seen perching on exposed twigs spreading and vibrating the wings and tail to clean themselves. This species has the fastest registered flight of any hummingbird recorded, or for almost any other bird for that matter, with short chase flights apparently being clocked in at 150 km/hour.

[*Colibri thalassinus thalassinus*.
Photo: Stephen Dalton/
NHPA]

Anna's Hummingbird had acquired the hybrid's aberrant song through imitation learning.

The majority of songbirds, parrots and hummingbirds have in common a syrinx structure controlled by internal and external muscles. Thus it has been suggested that trochilids are capable of song learning. Support for this assumption came from A. F. Skutch who observed a Blue-chested Hummingbird (*Polyerata amabilis*) singing the song of a Rufous-tailed Hummingbird. Other indirect evidence of song learning came from observations of song-sharing by neighbouring hummingbirds in Green and Little Hermits. Recently S. L. L. Gaunt and co-workers demonstrated that the male advertising song of an Ecuadorian population of the Sparkling Violet-ear, and of populations in Costa Rica of the Green Violet-ear, are of the same song type, while the advertising songs of conspecifics from distant neighbourhoods are different. These new bioacoustical data suggest that geographical variation in song is due to cultural drift acquired through song learning.

Learning a neighbour's song could have a distinct advantage. If a neighbour's song matches the stored image of one's own song, then an undegraded image of the neighbour's song is obtained. E. S. Morton has suggested that males can use such an image as a "standard" to judge degradation of the neighbour's song over distance. By doing so an individual could assess the distance to a singing neighbour and judge whether to ignore or to threaten him by countersinging or attacking. Interestingly, playback experiments with Great Tits (*Parus major*) support this hypothesis.

Hummingbird nestlings raised in exposed cup-shaped nests do not produce begging calls; their gaping behaviour is released by specific tactile stimuli of the female prior to feeding. In contrast, nestlings raised in semi-domed or completely domed nests (*Metallura*, *Agelaiocercus*) produce begging calls 4-6 days after hatching. Obviously these behavioural differences are adaptations to reduce predation on exposed nest-sites (see Breeding).

Contact calls between young and their mothers are only heard after the fledging of the chicks. These loud and often far-carrying calls of continuous high frequency between offspring and adult females help to localize the perching position of the mostly stationary fledglings in dense protective vegetation such as tree tops. As soon as the mother gets closer to the chick, the contact

calls are answered with increasing frequency, turning into loud begging calls when the female is in sight.

Alarm calls, similar to contact calls, but very shrill and uttered at higher frequency, are known from fledglings and adults of both sexes. These vocal signals are heard when predators like snakes, raptors or other large birds have been detected near a feeding-, lek-, or nest-site. Often alarm calls are associated with flight attacks.

The study of hummingbird voice is still in its infancy. Important questions to be addressed will probably concentrate on aspects of vocal acquisition over time, such as whether learning capacities are restricted to a sensitive phase during early development stages (classical approach), or to a circannual time window during which individuals are receptive to new acoustic input independent of age (flexible learning approach). Vocalizations related to food exploitation, territoriality, and other behaviour are other eco-ethological subjects poorly understood. Furthermore, shared notes, song delivery, and vocal learning may be helpful instruments in evaluating common ancestry in some species.

Food and Feeding

Thousands of New World plant species rely exclusively upon hummingbirds for pollination. As a consequence of the year-round high energy requirements of trochilids, plants that are pollinated by hummingbirds provide nectar at all times of the year, creating the opportunity of a phenological displacement of flowering times as a means of reducing interspecific pollen flow.

The evolutionary relationship between hummingbirds and their food plants is a good example of close mutualism, resulting in the many adaptations between flower and pollen vector that together is called ornithophily. Plants that have converged upon the "hummingbird" syndrome bear relatively large flowers, solitary or loosely clustered, often placed in a horizontal or pendent position. Typical hummingbird plants open their blossoms during the day; the flowers are generally brightly coloured, often red, orange or yellow, sometimes in combination with contrasting white corolla parts. Exceptions can be found in the Gesneriaceae, where some epiphytic species ex-

A male Green-backed Firecrown takes flight after bathing in the shallow water of a stream, while the accompanying female splashes her wings to dampen her plumage. The male of this species has an iridescent crown and weighs slightly less than the female, but otherwise the sexes are relatively similar. This is perhaps as a result of reduced polygamy in comparison with many other trochilines, but so little information has been gathered about hummingbird mating systems and life-history strategies that it is impossible to do more than speculate.

[*Sephanoides sephaniodes*, Chile.
Photo: Günter Ziesler]

Adult hummingbirds are too small, aerial and skillful in flight to have many major predators. They are usually out of the reach of terrestrial carnivores, and are excessively manoeuvrable in relation to most raptors. Forest-falcons (*Micrastur*) and pygmy-owls *Glaucidium* may take a small proportion of individuals at regular lekking or feeding sites, although this has never been reported. Amongst the most remarkable of hummingbird predators is the eyelash palm pit-viper (*Bothrops schlegelii*) of Central America. It has developed the trick of waiting patiently on forest flowers until they are visited by nectarivores, in this case the Rufous-tailed Hummingbird. When the unsuspecting visitor strays within range, the snake uncoils to strike, though not always with success. Despite these dangers, the largest toll is probably inflicted by birds, such as jays (*Corvidae*) and toucans (*Ramphastidae*), arboreal reptiles and possibly bats that devour eggs or nestlings. Although direct evidence for this type of predation derives from very few anecdotal accounts, a high proportion of hummingbird breeding attempts fail inexplicably, and it is likely that nest-robbers are frequently the culprits.

[*Amazilia tzacatl* *tzacatl*, Costa Rica. Michael Fogden/DRK]

Small endothermic organisms are under severe pressure, both to meet their daily energy requirements, and to accumulate sufficient energy reserves to survive periods of low temperature and darkness.

An abundance of high-quality food is thus vital, as are mechanisms to reduce energy consumption, such as torpor. This process, enacted here by a Bee Hummingbird, is apparently a common energy-controlling mechanism in hummingbirds, involving an 80-90% reduction in metabolic rate and savings of up to 60% of the energy used in the nocturnal resting phase.

[*Mellisuga helenae*,
Playa Larga,
Zapata Swamp, Cuba.
Photo: Robert Tyrrell]

hibit solitary inconspicuous whitish flowers. However, hummingbirds are attracted to these well-camouflaged flowers by their ornamental red-edged or red-centred leaves, a little-studied advertisement strategy in hummingbird-pollinated plants known as phyto-flagging.

Some of the commoner hummingbird-pollinated species belong to the genera *Zauschneria* (Onagraceae), *Delphinium* and *Aquilegia* (Ranunculaceae), *Mimulus* (Scrophulariaceae), *Aphelandra* (Acanthaceae), *Centropogon* (Lobeliaceae), *Cavendishia* (Ericaceae), *Columnnea* (Gesneriaceae), *Psittacanthus* (Loranthaceae) and *Heliconia* (Heliconiaceae). Most ornithophilous plants are dicotyledonous perennial herbs and shrubs, and only a few trees are pollinated by hummingbirds. Flowering trees with a very large nectar source, like many *Erythrina* (Leguminosae) species, are quickly occupied by territorial hummingbirds which remain in the tree tops for the whole flowering period until the nectar declines. By their doing so, pollen flow is greatly reduced. The most efficient pollinators of ornithophilous trees in America are passerines, such as orioles (*Icterus*), which move in groups between widely scattered flowering trees. The pollen loads from different conspecific trees, deposited on their feathers, support the obligate reproductive system of these trees: cross-pollination.

A closer examination of the mutualistic relationship between hummingbirds and their food plants has shown that pairwise co-evolution between a certain trochilid species and a certain plant species is non-existent. Plant-bird mutualisms are best described as having originated by "diffuse co-evolution", in which hummingbird-pollinated plants and their pollinators are represented by an array of populations generating multiple selective pressures.

K. A. Grant and V. Grant hypothesized that most of the Nearctic hummingbird-pollinated plants stem from bee-pollinated blue-flowering ancestors, and to a lesser extent from butterfly or moth pollination systems. An adaptive shift from blue to red flowers, which are not attractive to most insects (except butterflies and beetles), may have led to the evolution of ornithophilous flowers. This scenario may also be true for many Neotropical plant species. Most of their temperate relatives originated in tropical environments and followed the hummingbirds in the course of their various radiations.

The corolla of a typical hummingbird flower is often long, thickened, tubular in shape, and scentless. It contains sucrose-rich nectar which is taken by trochilids in hovering or hover-clasping flight. Many characteristics of hummingbird-pollinated

flowers, such as red colour, lack of odour, or the floral tubes with their thick walls, are adaptations either to avoid attracting insect competitors or to prevent nectar robbing. Ornithophily seems to be energetically expensive for plants. Although the energetic expenditures of plant reproductive strategies are still poorly understood, it is most likely that this process is energy-demanding. The evolution of ornithophily must therefore be viewed from the perspective of costs and benefits, obviously well balanced between hummingbirds and their plants.

Vision is the main sensory cue for foraging hummingbirds. Their colour vision is highly sensitive towards the red end of the spectrum (long wavelengths), whereas most insect colour vision is optimal at short wavelengths. The majority of ornithophilous flowers employ long-wavelength colours, reducing their attractiveness to most insects. Hummingbirds, according to current knowledge, have no sense of smell, but may well differentiate nectar by taste and concentration. However, they have no innate preference for red flowers, but instead associate particular colours with nectar content. Experiments by F. G. Stiles revealed that hummingbirds responded more to a stronger nectar concentration and nectar flow than to sugar composition (taste), and responded least to colour of food source, whether feeder or flower.

Since nectar is the major reward for hummingbirds when serving as pollen vectors, ornithophily has been examined mainly from the point of view of energetics. It has been proposed that feeding success depends on: the cost of acquisition, which is determined by body size; the energy value, which is influenced by co-evolutionary factors; and the time periods over which net energy benefits are obtained. If the absolute nectar accumulation rate were limited only by crop volumes and crop emptying rates, then trochilids could satisfy their theoretical energy needs during a short period of intensive daily foraging. Why is this not the case?

F. R. Hainsworth experimentally addressed the question of why hummingbirds adjust energy storage via meal size but maintenance via feeding frequency. According to his model, the answer depends on the weight of a meal as a cost. A meal of a particular size makes a particular contribution to the maximization of the rate of net energy gain, within constraints imposed by the total energy expenditure of the previous night. Meals of variable sizes have variable costs depending on their weight, and this uncertain variation may not permit a maximization of this rate. If hummingbird foraging strategy is looked at on a daily time scale, then short-term feeding behaviour may be sensitive to energy use for longer-term storage as well as short-term maintenance.

Hummingbirds are belligerent in defence of their territories or resources. Males often use exposed perches, which serve as vantage points whence interlopers can be detected. In this event threat calls are often given in conjunction with agonistic flights. If the newcomer does not vacate the territory, contests rapidly escalate, quickly culminating in physical combat. Individuals will sometimes grasp each other in flight, such that they tumble to the ground. While the claws are often the weapons used, the bill too is employed in attack, as seen in these two Ruby-throated Hummingbirds contesting the possession of a perch. Hummingbird fights can appear surprisingly vicious, but they are rarely harmful beyond the loss of a few feathers.

[*Archilochus colubris*,
Sodus Bay,
New York, USA.
Photo: Robert Tyrrell]

Seasonal changes in day length, as in North America and southern South America, can also influence the apportioning of energy to maintenance and storage, while energy-demanding activities like reproduction, moult or migration will also influence feeding behaviour. Depending on demand for and availability of food, short-term adjustments in daily rates of net energy gain may suffice for some seasonal effects such as daylight variation. If foraging time is limited (migration), or if expenditure is increased relative to food availability (reproduction), then longer-

term accumulation of energy might be required in "anticipation" of demand.

Hummingbird flowers supply their pollinators with large amounts of nectar per flower per day, but do not satisfy their nutritional requirements at one visit. However, P. Feinsinger discovered in a Costa Rican heliconia (*Heliconia psittacorum*) that only some flowers contain abundant nectar (bonanzas), and some essentially none (blanks). Since hermits are the main pollinators of heliconias, Feinsinger suggested that these hummingbirds must

visit many flowers in order to encounter one with a high nectar content, thus the "bonanza-blank pattern" might support cross-pollination in *H. psittacorum*. In another field study on the pollination of successional plant species in the cloudforest at Monteverde, Costa Rica, Feinsinger observed that flowering was staggered among plant species, resulting in a constant nectar supply to trochilids. In five plant species that were closely investigated, measurements of nectar volume indicated that the bonanza-blank pattern was widespread. He concluded that plants may conserve energy by producing large numbers of nectarless flowers and a few bonanza flowers so that hummingbirds are forced to visit many flowers to meet their energetic needs. By their visiting many flowers, cross-pollination is promoted.

Many studies show a significant correlation between the body mass of hummingbirds and the energy value of the nectar produced per flower and day. Hummingbirds have a greater body mass than most insects, and this, combined with endothermy, increases their energy requirements, necessarily leading to increased mobility. This considerable activity radius increases the probability of cross-pollination and the genetic recombination of flowering plants. Only a few species of large hawkmoths have higher energetic needs when active than hummingbirds but, in common with other insects, reduce their metabolism when weather conditions are unfavourable. Hummingbirds use nocturnal torpor for short-term energy savings, remaining active even under inclement conditions during the day when insects are inactive, and are thus more reliable pollinators where cool or rainy conditions occur regularly. Hummingbirds, like other nectarivorous birds, forage throughout the day, with higher levels of activity at dawn and dusk, although only a small fraction

of each hour may actually be spent feeding. Insects search for nectar only at certain periods of the day. Due to their relatively high body mass hummingbirds have a much higher potential mobility than most insects. Foraging distances of more than 1 km have been reported for trochilids visiting widely distributed flowering shrubs in a single feeding bout. For most insects the travelling distance between successive flower visits tends to be much smaller and foraging strategies are much more stereotypic. A long-lived pollinator such as a hummingbird, experiencing several flowering seasons during its lifespan, combined with the capacity of its excellent spatial memory, can easily remember locally or patchily distributed flower stands. Thus, the floral environment for trochilids is much more differentiated in time and space than for insects.

The most striking feature when considering hummingbirds and their flowers is the close fit between their bill shape and length and the flowers on which they feed. Like the insect feeding apparatus, bills are evolutionarily plastic structures. Selective forces have had a much stronger impact on morphological co-adaptations between bird bills and flower shapes than between the snout structures of bats and bat-pollinated flowers. This may generally explain the higher species diversity of flower-visiting birds and insects as compared to bats.

Bill morphology influences the efficiency with which hummingbirds forage at each flower and determines which flower types can be exploited. P. Feinsinger and R. K. Colwell suggested five major flower types, often sympatric within a tropical floral community, according to habitat, zone within a habitat, dispersion, and flower characters. The five types are: (1) "Dispersed rich flowers" with long or curved corollas that exclude most in-

Flowers are the main source of food for hummingbirds, and for thousands of New World plants, hummingbirds are the key to reproduction.

Because of this interdependency, selective processes driven by competition for resources and pollinators have shaped these organisms, producing a fantastic array of colour and form.

The Blue-fronted Lancebill, here visiting a vivid inflorescence of nectar-bearing flowers, is a member of the genus *Doryfera*, which was previously grouped with hermits because of the similar musculature and vocalizations. This genus has subsequently been regrouped in the heterogeneous trochiline assemblage, of which it is potentially an early evolutionary state, and merely convergent with hermits in behavioural and morphological traits, as they are adaptations for foraging, communication and locomotion in the dense forest understorey.

Photo: Luis Mazariegos]

The Bronzy Inca, here attending banana blossom, often begins feeding well before dawn, so urgent is its year-round requirement for nectar. As a consequence of this demand, plants with flowers designed to attract hummingbirds often provide nectar constantly, unlike the seasonal production found in insect-pollinated plants. Hummingbirds consume a surprisingly large amount of insect food, usually in the ratio 1:9 with nectar. It was previously suggested that hermits tend to rely on a greater proportion of insects than do trochilines, but investigations have not supported this idea. Small quantities of vegetable matter are also taken by many species.

[*Coeligena coeligena ferruginea*, Cauca, Colombia. Photo: Luis Mazariegos]

sects and most hummingbirds with short to medium-sized bills; their nectar reward is substantial. Typical plant species of this type are often vines (*Mandevilla hirsuta*, Apocynaceae) or shrubs (*Centropogon*, Lobeliaceae). (2) "Clumped rich flowers" with long corollas and high nectar production, often occurring in dense clumps; heliconias are a prime example. (3) "Dispersed moderate flowers" with moderately long corollas, excluding many insects but allowing most trochilids to exploit a moderate amount of nectar. Examples are shrubs like *Hamelia* (Rubiaceae) and vines (*Tropaeolum*, Tropaeolaceae). (4) "Clumped moderate flowers" with small to medium-sized corollas and little nectar reward, available especially in the late afternoon. These flowers exist in dense clumps on trees or shrubs, for instance some lobelias. (5) "Insect flowers" with short corollas containing minimal amounts of nectar, for example *Lantana*, *Stachytarpheta* (Verbenaceae) and *Asclepias* (Asclepiadaceae); they are often pollinated by insects.

Bill shape, which varies widely among trochilids, largely influences the efficiency with which the birds forage at each flower and determine the type they can successfully exploit. Hermits and certain trochiline species have long and straight or long and slightly decurved bills providing access to long-tubed flowers, rich in nectar. At the other extreme, many trochilines have short, straight bills allowing them to exploit a variety of "moderate" or "insect" flowers opportunistically. However, some short-billed species, like *Heliothryx*, are nectar robbers, taking nectar from flowers by piercing the corolla base.

Questions of wing-loading, the ratio between body mass and the area of the outstretched wings, and the energy required for hovering have also been used in the interpretation of hummingbird foraging modes. This energy depends on body mass and

wing-loading, which varies with air density. Hummingbirds with high wing-loading expend more energy while hovering, especially at higher elevations, but have greater flight acceleration and manoeuvrability than those with low wing-loading. Birds with high power requirements establish territories around clumped flowers, while those with low requirements exploit dispersed or insect flowers with relative efficiency.

In more complex tropical environments, hummingbird communities may be grouped into different foraging modes according to the power required. "High-reward trap-liners" with specialized long bills (almost all of the hermits and some non-hermits) visit widely scattered long-tubed, nectar-rich flowers following a repeated foraging circuit, or trap-line. "Low-reward trap-liners" have smaller straight bills and visit dispersed but less specialized flowers. "Territorialists" occupy "clumped moderate" and "clumped rich flowers". These are generally small hummingbirds with short bills and a moderate to high power requirement, and they defend feeding territories against any potential hummingbird intruder. "Territory-parasites" frequently occur in "clumped moderate" flowering stands, parasitizing the territory holder. These parasitizing trochilids may be large with medium-sized bills and high power output, and tend to ignore aggressive displacement displays by the territorial bird, or they may be very small like *Lophornis* and *Atthis*, resembling large insects, and feed at areas within a territory not directly visible or regularly inspected by the resident bird. "Generalists" have short to medium-length bills, small to medium body mass, and a moderate power requirement. They behave opportunistically, switching from dispersed moderate to clumped flowers. These generalists are often called "facultative trap-liners" since they

Many species of hummingbird visit Heliconia flowers, often as bizarre and beautiful as the birds themselves. Indeed,

White-bearded Hermits and other Phaethornithinae are the primary pollinators of these pendant candelabra-like structures which commonly festoon the undergrowth of Neotropical forests. Heliconia has been found to follow a "bonanza-blank pattern", in which some flowers are rich in nectar and others contain very little. By this method, they are thought to reduce energetic costs and increase the probability of cross-pollination, as hermits have to visit more flowers to meet their nutritional requirements. Sitting quietly by a clump of flowering Heliconia, an observer might notice that it is visited by an individual hermit at regular intervals. The reason for this is that hermits are "high-reward trap-liners", visiting a sequence of widely dispersed nectar-rich flowers in a repeated circuit. The advantage of this technique is that each flower is given sufficient time to renew its nectar resource. Between trap-lining and territoriality, many intermediate forms of resource defence and exploitation are found in hummingbirds, depending on flower dispersion, morphology and nectar reward. The behaviour of individuals or populations can vary spatially and seasonally, depending on these parameters. In addition, hermits often pick both spiders and their prey from webs, or insects from vegetation. They rarely hawk for flying insects, although this is a common foraging technique employed by many trochilines.

may switch to low-reward trap-lining depending on the local nectar availability and competition for food.

In Central America, where the dynamics of local hummingbird communities are seasonally influenced by North American migrants, different foraging guilds can be found. In a Mexican hummingbird community, J. L. Des Granges distinguished three well-defined foraging guilds: a resident guild of tropical species, inhabiting specific habitats; a guild moving through several habitats following seasonal flowering periods (wanderers); and a guild of strictly seasonal migrants. According to this study most residents could be viewed as territorial species, whereas the wanderers could be categorized as trap-

liners, being mainly non-territorial. Like the residents, the migrants established territories and defended flowers that provided nectar surplus to the energetic needs of residents and wanderers. Des Granges also noted spatial segregation of species utilizing flowers at different heights.

When hummingbirds visit their food plants "nectar mites" feeding inside the flower on nectar and pollen often make use of the avian visitor for a change of blossom. Within a few seconds they climb to the bird's bill and move to the nasal cavities, where they remain until the bird visits another host plant. The mites do no harm to the bird. They undergo their complete reproductive cycle in hummingbird flowers, which they identify as host plants by odour. They complete the stages from egg to adolescence within four to seven days, then wait for another hummingbird to move them to new host flowers for another reproductive cycle.

Hummingbirds in North America and Colombia have been observed making use of sapsucker (*Sphyrapicus*) pits in living trees, consuming the sugary sap and catching insects attracted to this food source. The Ruby-throated Hummingbird of North America, in particular, seems to benefit from these sugar sources during early spring migration when plants are just beginning to flower. Other trochilids (*Leucochloris*, *Chlorostilbon*) in Santa Catarina, Brazil, have been recorded feeding on the sugar-containing excrement of coccids (scale insects) during the southern winter when flowers are scarce.

Hummingbirds often supplement their usual food with pollen gathered when drinking nectar. Although pollen contains essential amino acids, the major protein supplement comes from arthropods. It has often been stated that hermits differ from trochilines by their higher insect consumption, but this idea has not been confirmed by laboratory or field studies. F. G. Stiles, for example, concluded from his detailed work in Costa Rica that there is no support for the view considering hermits to be more insectivorous than trochilines. As a general approximation, most hummingbirds consume a daily ratio of nectar to arthropods of roughly 9:1 by mass.

Hermits, which exclusively live in the understorey, are hover-gleaners, collecting their arthropod prey from the plant substrate or spiders' webs. The Band-tailed Barbthroat (*Threnetes ruckeri*) forages for jumping spiders; the White-tipped Sickbill

The Oasis Hummingbird lives in relatively inhospitable habitats of the Peruvian and Chilean deserts, occurring in dry coastal hills, arid scrub and oases, where cactus flowers are an important source of nourishment. It is also quick to take advantage wherever man has increased the local abundance of flowering plants by frequenting towns and gardens.

*A remarkably diverse hummingbird community flourishes at relatively high altitudes in páramo habitats. The Shining Sunbeam, for example, feeds on flowering terrestrial bromeliads and composite shrubs in these areas, often competing with hillstars (*Oreotrochilus*), trainbearers (*Lesbia*) and thornbills (*Ramphomicron*, *Chalcostigma*). As flowers of páramo plants are generally numerous but small, the bills of attendant hummingbirds tend to be rather short.*

Typical hummingbird flowers contain sucrose-rich nectar, open diurnally and tend to be large, brightly coloured and eye-catching, with long, tubular and scentless corollas. Red colours predominate because of the spectral sensitivity of hummingbird eyes. Some dull-coloured flowers are surrounded by colourful leaves so that they are conspicuous to nectarivores, a phenomenon known as phyto-flagging. While some flowers are favoured by particular species of hummingbird others attract a variety. This epiphytic bromeliad is visited by a Violet Sabrewing and a Green-crowned Brilliant, and in some areas popular flowers will attract more than ten species in a day. In species-rich hummingbird communities, sympatric taxa often differ widely in body mass and bill morphology, as natural selection tends to minimize direct competition. When species are more similar in morphological respects they often diverge ecologically by employing different foraging strategies or microhabitat preferences. Hummingbird foraging behaviour is exploited by "nectar mites" that feed inside flowers and use birds as their mode of transport, crawling on to their bills, sheltering in their nasal cavities and hitching a ride to the next plant.

The Broad-tailed Hummingbird usually feeds just above the ground on insects and the nectar of flowering shrubs and low perennials. This bird has been startled while feeding on the beard tongue (*Penstemon barbatus*), and in its haste to escape danger small beads of nectar spray from its bill. Its modified wingtips, featuring reduced outer primaries, are thought to function in mechanical noise production, as a wing-snapping sound is regularly heard from males.

[*Selasphorus platycercus*, Mt Lemmon, Arizona, USA. Photo: Robert Tyrrell]

(*Eutoxeres aquila*) seems to be an exception among the hermits with its habit of hawking for flying insects.

In most trochilines such hawking is a common foraging mode. Flies and wasps are the dominant prey, but spiders, ants and small beetles have also been found in the stomachs of non-hermits. Both *Heliothryx* species are hover-gleaners, making use of the complete vertical stratum of the tropical vegetation from close to the ground right up to the canopy; according to F. G. Stiles they take more spiders than flies. A spider specialist among the trochilines is the Tooth-billed Hummingbird (*Androdon aequatorialis*), which probes for prey in rolled-up leaves or cavities along roadsides, where hunting spiders often hide.

Observations that hummingbirds can rely over extended periods on arthropods alone must be viewed with some scepticism, as does a report that arthropod abundance and not nectar availability determines the onset of breeding in dry areas. Nectar seems to be the only energy source that could supply the daily requirements of a high-metabolism animal like a hummingbird. It has been reported that breeding female hummingbirds spend more time foraging for arthropods than do males at the same time in the same localities, but foraging for nectar still accounts for most of the daily activity pattern.

There is no evidence that hummingbirds can extract arthropods from flowers with the bill or tongue. It is more likely that selection for nectar drinking was the major evolutionary force in the development of the hummingbird feeding apparatus, so that bill morphologies in turn constrain foraging methods to gleaning and hawking when feeding on arthropods.

Breeding

Male hummingbirds are polygynous, mating with several females during a reproductive period. In most species studied the male associates with the female only during a short period to fertilize her eggs. All remaining reproductive responsibilities like nest building, incubation, and rearing the young are carried out solely by the female. There are a few reports, involving the Sparkling Violet-ear and the Hairy Hermit, of males participating in incubation or feeding young, but recent studies of the reproductive biology of both species did not confirm parental care by males as a regular species-specific behaviour pattern. Since both species are sexually monomorphic, the male participation in incubating the eggs or rearing the young might easily have been a misinterpretation. The same is true for the White-necked Jacobin, for which observations of male incubation are said to have been made. Again, a closer look at the external morphology of the species reveals that some females may moult into a sexually distinguishing plumage only in their second year. When entering

their first reproductive cycle they may still look much like adult males. There are a few other single reports of male incubation in North American trochilids, namely Ruby-throated, Rufous and Anna's Hummingbirds, but whether these observations are random exceptions or commoner phenomena still needs verification. By no means can broad generalizations be made about active male participation in reproduction for any of the North American species solely on the basis of these observations.

Interactions between male and female hummingbirds are normally restricted to the short period of sexual synchronization. Males advertise themselves by song, iridescent plumage (Trochilinae), and aerial flights either at traditional display grounds, or leks, from dispersed singing posts, or at their feeding territories where they are visited by females when receptive to copulation. The male behaviour for attracting females is similar to the defence display directed towards food competitors, predators or any intruder to the feeding ground. By specific behavioural triggers, mainly perching motionless near an advertising male, the female switches the agonistically orientated display of the male into one which is sexually directed and leads to copulation. Thereafter, both sexes separate again. Males of the Fiery-throated Hummingbird and Purple-throated Carib, among others, show a resource-based mating system, allowing conspecific females to enter their otherwise aggressively defended territories to feed on nectar-rich flowers. Females may copulate with males on these feeding grounds or may collect nectar for themselves or their offspring during the period of reproduction. In hillstars (*Oreotrochilus*) only females hold territories, on which they are visited by males in the breeding season. For one species, the Andean Hillstar, the female has been observed to feed the male prior to mating. Loose pair-bonds with one or two brooding females have been reported for males of the Hairy Hermit along sections of small forest streams, the males protecting their mates from other hermits which approach and inspect active nests in the search of nesting material.

The onset of breeding in hummingbirds is very variable from species to species and from region to region. As a general rule the peak of reproduction in most trochilids is closely associated with the months of mass-flowering of many ornithophilous flowering plants. In the high Andes of Ecuador, violet-ears (*Colibri*), metaltails (*Metallura*), trainbearers (*Lesbia*) and pufflegs (*Eriocnemis*) begin to breed during most of the wet season, often around mid-October, and continue to March or sometimes April. At similar altitudes further north or south, reproduction starts about three months earlier or three months later than in the mountain regions near the equator, the breeding season often lasting only a few weeks. At lower altitudes, seasonality of the reproductive cycle declines and nests of several species may be found throughout the year, with decreasing numbers during the peaks of the

Hummingbird bills are evolutionarily plastic structures, and natural selection has sculpted various styles.

The Green-fronted Lancebill, for example, has an extremely long, straight bill for extracting nectar from tubular corollas, such as this *Psammisia ramiflora* flower, but it cannot probe into curved flowers. The Green Hermit has a slightly decurved bill, allowing it to feed in a wider variety of plants, including these *Erythrina* flowers, while the White-tipped Sicklebill specializes on curved flowers like those of *Heliconia reticulata* but cannot utilize long, straight corollas.

The Scintillant Hummingbird has a short bill, ideal for small flowers, such as *Vaccinium poasanum*. Close mutualism between hummingbirds and flowers is termed ornithophily, a dynamic strategy with finely balanced costs and benefits for both parties.

There is no evidence for any exclusive inter-relationship between single species of plant and hummingbird, and mutualism is perhaps best described as "diffuse co-evolution", a process by which a suite of bird and plant populations combine to generate selective pressures, through which the shapes of flowers and hummingbird bills are determined. It has been hypothesized that insect-pollinated ancestors of ornithophilous plants switched from blue to red colours as a result of differences in the optical design of their pollinators: the compound eyes of insects are sensitive to blue light while those of hummingbirds are most sensitive to red light.

dry and wet seasons; these seasons differ greatly from region to region. The Hairy Hermit on Trinidad and Tobago breeds mainly during the dry season, from January to April, with declining reproductive activities from the onset of the wet period in May. In the Amazon region of Brazil the same species also nests during the dry months, which there last from May to October. The Rufous-tailed Hummingbird, a species which occurs from central Mexico to western Venezuela and western Ecuador, breeds virtually throughout the year, except during its annual moult, with locally different peaks of reproduction. The same applies for the cave-nesting hillstars of the high Andes. North American trochilids (*Selasphorus*, *Archilochus*, Costa's Hummingbird, *Calothorax*, *Stellula*, *Eugenes*, *Lampornis*) chiefly breed during

spring to late summer, with the exception of Anna's Hummingbird, which generally nests during winter; sometimes incubating females of this species are exposed to frost and snow. Its early breeding has been explained as a strategy of competition avoidance with other temperate trochilids which invade the coastal Californian scrub zone (chaparral), one of the major habitats of the species, during the flowering peak of several nectar-rich food plants, such as gooseberry and fuchsia, in spring.

Increase in testis size as an indication of breeding condition has been studied in detail only in Anna's Hummingbird. In this species a testis volume of 4 mm³, or greater, has been taken to be an attribute of birds ready for reproduction. Broad generalizations have been made with regard to testis volume and the onset of breeding based on these findings, and it is fairly clear that a testis size of 6 mm³ is a reliable indicator of reproduction in many medium-sized hummingbirds throughout their distribution range. However, reproductive physiology in the great majority of trochilids remains unstudied. Completion of moult may be a general prerequisite for breeding.

Females of many Trochilinae select nest-sites after a nearby rich nectar source has been located. Suitable branches for nesting are first inspected by her hovering above the surface and touching down over the spot repeatedly. Nest-sites of hermits, however, are not associated with nearby food sources. Females of this subfamily frequently cling with their feet to suitable green leaves of palms or *Heliconia* stands, to which they later attach their cone-shaped nests. This behaviour may serve to test the strength of the stratum for the purpose of nest construction.

Hummingbird nests are tiny and of various shapes, and they are placed at a wide range of heights, locations and substrates. Most nests are of a cup-like architecture, saddled on branches and large leaves (*Anthracothonax*, *Florisuga*); placed in forked twigs (*Thalurania*); glued to rocky walls (*Oreotrochilus*); hidden underneath a bulk of dense thickets overhanging a slope (*Eriocnemis*, *Lesbia*); attached to lianas (*Heliothryx*); or fastened beneath a pendular leaf which provides shelter from rain (*Haplophaedia*, most Phaethornithinae). Some genera like the sylphs (*Agelaiocercus*) construct completely domed nests, others like the metaltails have semi-domed ones. In sylphs, males too have been observed building "nests", but these serve only as nocturnal sleeping shelters to which they return each night.

Plants provide nectar to attract hummingbirds. During the feeding process, pollen is attached to the bird in such a way that it is transported to the next flower visited, which may thereby be fertilized. By this process of pollination, the Ruby-throated Hummingbird performs a vital ecological service. Due to a lack of food in winter, it is forced to vacate its North American breeding range. Small groups migrate directly across the Gulf of Mexico, flying up to 1000 km. The birds have been calculated to accrue sufficient fat reserves to travel 40 km per hour for 25 hours: only just enough to cross the sea!

[*Archilochus colubris*,
Sodus Bay, New York.

The anthers of some flowers are designed to dab pollen on the crowns of their visitors, as illustrated by this White-throated Hummingbird, while others reach their belly plumage, as in the hibiscus here attended by an Eastern Long-tailed Hermit. In comparison with insects, hummingbirds are active for a greater part of the day, tolerate poorer weather, have superior spatial memory and live longer. They also have higher energy needs due to their endothermy and greater mass, which lead them to be more mobile in search of food, a factor which further increases the likelihood of cross-pollination.

Some species, such as the Stripe-tailed Hummingbird, have learnt to bypass the requirement for long bills by occasionally piercing the base of flowers and thereby gaining access to the nectar. By doing so, they also bypass the plant's pollination system and thus make no contribution to its reproduction. For this reason, ornithophilous flowers often possess thick sleeves to minimize the incidence of nectar theft. The Stripe-tailed Hummingbird is locally common from Mexico southward through Central America in damp montane forests.

Patricia Fogden]

Nests can be found at all heights, from a few centimetres above the ground (*Phaethornis*) to tree-top levels at 10-30 m (*Anthracothorax*, *Eulampis*, *Heliomaster*, *Eugenes*). Even within a species, nest-sites may vary from low secondary vegetation to the canopy level. Although all hummingbird nests are accessible in flight, only a few species build them completely exposed, for example members of the genera *Anthracothorax* and *Heliomaster*. Nests are commonly placed in locations giving some protection from direct sun and rain by overhanging leaves. For nest-site selection balanced microclimatic conditions like temperature and humidity seem to be major requirements for ensuring the successful development of the embryos. Thus nests are often located near waterfalls, forest streams or lake shores.

Many hummingbirds decorate the outer wall of the nest with pieces of lichen, moss, dead leaves, rootlets, bark and so on, making it almost indistinguishable from the immediate surroundings, and thus difficult for predators to locate. Most members of the Trochilinae have nests of cup-shaped open construction consisting of two different substrate layers. The outer surface often contains the coarse materials mentioned for optimal camouflage, the whole bound together with spider web into a solid mass. Soft, fine plant materials, and occasionally small feathers or animal hair, are used for the inner nest lining, providing optimal insulation during incubation. Among the exceptions are nests of high-altitude hummingbirds, like the Sapphire-vented Puffleg (*Eriocnemis luciani*), in which the inner soft cup layer is absent. Montane trochilids often build bulky nests of moss, pieces of grass and lichen held together with spider web, frequently placed underneath dense thickets of grass overgrowing steep slopes and roadbanks, which provide ideal microclimatic conditions and protection for the eggs and young.

Hermit nests are mainly attached to the inner side of a palm or *Heliconia* leaf tip, or, as in the Sooty-capped Hermit (*Phaethornis augusti*), suspended from above by a single strand of spider silk. In order to achieve a stable vertical nest position, organic matter such as fine rootlets, leaves, parts of downy pappus, and so on is attached to the lower part of the nest, which may triple the size of the actual construction. To keep the hanging position of the nest level, lumps of clay or pebbles are woven in below the point of attachment. Nests of the Sooty-capped Hermit are regularly found inside empty buildings or beneath bridges.

Members of the genus *Phaethornis* construct compact pendant nests of soft plant fibres and spiders' webs attached to the inner side of elongated plant leaves. All other hermit genera build similar but loose nests with open walls of coarse material such as stiff rootlets or dry pieces of leaves and liverworts. Generally, the eggs can be seen from below since much light passes through the construction. This nest structure is an adaptation to the wet lowland forests where most hermits occur. The regular heavy rain showers have no cooling effect on the eggs and embryonic development since water passes through the nest quickly. The poor insulation provided by the coarse nest material is largely compensated for by the warm ambient lowland temperature.

The nest construction process lasts around 5-10 days for most species studied. Building begins in the early morning and continues actively until late morning, slowing to a stop around mid-afternoon. In the Rufous-tailed Hummingbird and many North American trochilids, nest construction may continue all day, depending on local weather conditions. The female makes alternating trips between gathering plant down and spiders' webs. The sides and rim develop as the female sits in the nest, pushing nest material with her breast while turning frequently. Often nesting material is re-used in a new nest or the old nest serves as a platform for a subsequent construction: a female Blue-throated Hummingbird (*Lampornis clemenciae*) has been known to build five consecutive nests on the first one, creating a nest tower of over 20 cm. Females repair nests regularly, especially during the incubation period.

The clutch of all hummingbirds consists invariably of two eggs which are white, non-glossy, and of an elliptical oval shape. Only in the Stripe-tailed Hummingbird (*Eupherusa eximia*) of Central America have bright pinkish eggs been reported, besides the regular white clutches. This difference in egg coloration is not genetic but is caused by the red oak lichen sometimes used in the lining of the nest. Rain leads to a permanent chemical colour reaction with the eggs and the belly feathers of the incubating female, which are regularly stained with the same pinkish hue.

In some hermits (*Glaucis*, *Threnetes*), nests with three or four eggs have frequently been found, but these are apparently attributable to more than one female, so-called egg-dumping, and females of both genera regularly inspect active nests of conspecifics.

Occasionally three eggs have also been found in the nest of a few trochilines (*Colibri*, *Amazilia*, *Calypte*), and again it is most likely that the additional egg was laid by another female. Eggs are usually laid in the early morning. Normally there is an interval of two days, rarely one or three, before the second egg is laid. Eggs are sometimes laid before the nest is completed; females then continue construction between incubation spells. Incubation may begin when the first egg is laid but regular incubation starts with the second.

Hummingbird eggs are naturally very small. Eggs of the tiny Bee Hummingbird from Cuba average 11 x 8 mm, while those of the much larger Giant Hummingbird of the Andes have a size of 20 x 12 mm. Egg mass varies from 0.4 g in extremely small species, such as the Reddish Hermit and the Frilled Coquette (*Lophornis magnificus*), to 1.4 g in the Giant Hummingbird. In relative terms, however, two eggs of the small species would equal roughly 35% of female body mass, while in the Giant Hummingbird the figure is about 15%. The severe energy constraints

The bill of the Sword-billed Hummingbird, reaching 12 cm in length, is the longest of any trochilid, and the bird needs to hold it up towards the vertical when perching or in flight so as to maintain its balance. Despite this minor inconvenience, the species is perfectly adapted to extract nectar from the long tubular flowers of Andean plants such as *Datura sanguinea*. The hummingbird has evolved in tandem with flowers like this and is their most frequent visitor in many areas. To a certain degree this kind of mutualism is beneficial to both parties, guaranteeing the flower a dedicated pollinator and eliminating competition for the hummingbird. The system does, however, leave itself open to cheats, as illustrated by this Black-tailed Trainbearer, piercing the *Datura* flower at its base, taking the nectar supplies coveted by the Sword-billed Hummingbird and failing to pollinate the plant.

As they process such large quantities of liquid food, hummingbirds defecate frequently. A hummingbird will pass a meal of nectar from the crop into the intestine in only about four minutes, and transit through the intestines often takes less than 15 minutes. During this remarkably short time the bird can extract up to 99% of the ingested sugar glucose, due to the high number of glucose transporters in its intestinal tissue, quite possibly the highest density in any vertebrate and perhaps the maximum structurally possible for an intestinal membrane. This Magenta-throated Woodstar takes in the sugary secretions of a Poinsettia flower while simultaneously eliminating the waste products of nectar digestion. This species is common throughout its Central American range, feeding on an especially wide variety of plants in most habitats except dense forest and at all altitudes below 1500 m.

DRK]

on females of small species may explain why single annual broods are much more common in these species than in medium-sized to large ones.

The incubation period for the majority of trochilids lasts 16-19 days, about 2-5 days longer than in songbirds. The shortest periods known are for the White-eared Hummingbird (*Basilinna leucotis*) from Central America, at 14-16 days, whereas hillstars and other high-Andean species can attend the clutch for 22-23 days.

For the few species studied in detail females incubated during 75-90% of the daylight hours. How do these birds, which normally consume nectar every 6-10 minutes, meet their energy requirements during this prolonged stationary period? Some physiologists suggest that the metabolic rate of a bird at rest can supply all the heat required for incubation. Others conclude that the energy requirements for incubation must be supplied by supplementary heat production which would necessitate an increased food intake. A closer look at the thermoregulatory ability of incubating females reveals that they compensate for a reduced food intake during long attentive periods by reducing their body temperature from 41°C to about 32°C, resulting in energy savings of almost 50% during the day.

Depending on the timing of the start of incubation, eggs may hatch at intervals of 48 hours or almost synchronously. Hatchlings of all hummingbirds are altricial: nearly unfeathered, blind and helpless. During their long nestling period of 23-26 days, or in high-Andean trochilids 30-40 days, the following three well-differentiated morphological stages of development can be observed.

In the first, from day one to about day five after hatching, the nestling is nearly naked except for two dorsal rows of neossomite down about 5 mm long, and its eyes are still closed. During this stage the chicks, generally two in number, are inactive in the nest. When the female arrives with food she lands on the edge of the nest and touches the nestlings behind the eye-bulges with her bill. In response to this stimulus the young birds gape and

are fed by the female, which inserts her fine bill into each nestling's mouth and regurgitates food consisting of nectar and tiny arthropods from her crop into that of the chick. Gaping in nestlings of that age can easily be artificially induced several times by touching the eye-bulges with a matchstick. No begging call can be heard at this stage.

The second stage, from day six to day nine, when the eyes begin to open, is the period of major feather development on the wings, tail and back. The dorsal down is not shed but remains attached to the contour feathers. Begging calls are still not heard at this time.

The third stage of nestling development covers day ten until fledging, at around days 17-19. By the beginning of this period chicks are almost completely feathered and often sit on the edge of the nest facing outward, but they still fail to give begging calls.

During the second and third stages, the female gradually approaches the nest and begins to hover over the feathered young with an increased wingbeat frequency that is clearly audible. When the dorsal neossomite down attached to the chicks' contour feathers is visibly agitated by the resulting air movement, the chicks invariably begin to gape; gaping can easily be triggered in the chicks at this age of development by blowing with a straw on their dorsal neossomites. The gape-releasing stimulus during this stage of development has changed and no touching of the eye-bulges by the female can be observed. When gaping, and also during feeding, the chicks raise themselves only slightly and remain in a rather stooped position in the nest.

With increasing age, from about day 15 onwards, chicks often sit at the edge of the nest during the day, mostly with their backs turned away from the cup. At feeding time the female hovers just above the chicks, causing movements of their dorsal neossomite plumage, and only after this stimulus will the nestlings gape and then be fed. In all trochilids studied raised in an open cup-shaped nest, begging calls are still not heard at this

Feeding during hovering flight, this Buff-tailed Coronet pays an energetic cost while accruing nutritional benefits. To reduce energy requirements, hummingbirds usually take the opportunity to rest while feeding, sometimes maintaining balance with open wings as in this Fire-throated Hummingbird, but ideally with their wings closed and at rest, like this Green-fronted Brilliant. Hummingbirds spend over 70% of each day perching, partly to offset their flight costs, but also because it takes around four minutes to empty the nectar-filled crop into the intestine. As a result, hummingbirds that have filled their crops with food are forced to delay foraging until space is available. They are thus unable to exploit nectar resources any faster, and have even been observed feeding at four-minute intervals.

nestling stage. When the dorsal down from laboratory-reared hummingbirds was removed with forceps on day 10 after hatching, gaping reactions were not elicited by the female's hovering closely over their backs. However, when a hovering female landed on a chick's back it gaped immediately and was fed. Two days after the neossoptile plumage had been removed, gaping reactions could once again be observed with the approach of the female. The absence of tactile stimulation suggests that optical signals may by then have become adequate stimuli. Begging calls are given by hummingbird chicks only after fledging. They normally give loud begging calls, irrespective of the presence of the female, but call more vigorously when she is in view.

Because hummingbirds forage by hovering they can no longer climb with their feet, which serve only for perching. Consequently, they build exposed but camouflaged nests easily accessible in flight. The often exposed nest-site and low reproductive output probably favoured the development of the highly specific gape-response behaviour. Loud begging calls of the offspring, as well as uncontrolled begging and gaping movements through non-specific causes like vibration of the nest by wind, would be types of behaviour that could potentially betray the nest-site to predators such as tree lizards, snakes and birds. Thus, the highly specific stimuli which elicit gaping by unfledged hummingbird chicks are most likely adaptations for reducing predation on exposed nest-sites. Consistent with this observation is the fact that chicks of those hummingbirds like sylphs and metaltails which build domed nests give begging calls very shortly after hatching, presumably in response to tactile stimuli from the female as she enters the nest.

As part of a predator-avoidance strategy female hummingbirds never approach the nest directly. They often fly to the nest-site in fast semi-circles or with zigzag manoeuvres. A surprising form of anti-predator behaviour has been observed independently by R. Cintra and K. L. Schuchmann in the two species of fairy (*Heliothryx*). When leaving the nest after each brooding or feeding period, the female, with wings and tail fanned out horizontally and with only very slight aerodynamic corrections, performs a spiral gliding flight into the understorey. This downward movement strikingly resembles that of the falling dead leaves seen continually in humid tropical forests. When both gliding patterns, that of the bird leaving the nest and that of the falling leaves, were compared with regard to their velocity, identical speeds were recorded. The gliding flight posture and speed of *Heliothryx* most likely mimics falling leaves and protects the nest, nestlings and adult against predation.

When leaving the nest, females of the White-necked Jacobin exhibit a moth-like flight with rising and falling manoeuvres. This behaviour may be interpreted as a distraction display because it is conspicuous, attracting attention to the bird itself rather than to the nest.

Female hummingbirds feed their young throughout the day roughly twice per hour, and brood them until an age of 7-12 days. Studies of thermogenesis in nestlings involving the Reddish Hermit and the Blue-throated and Broad-tailed Hummingbirds indicate that the development of thermal control falls into that period. Thereafter, the young can regulate their body temperature and metabolism and do not depend on extra maternal warming.

Hummingbird nestlings grow quickly, reaching almost 80% of their adult mass within 10-12 days. For a minuscule organism like a chick the use of nutrients for fast attainment of heat-retaining tissue may be of greater selective advantage than its employment for maintenance functions. However, unfavourable weather conditions may retard development and extend the required nest period for several days. Weather conditions actually have a strong impact on nestling mortality during the days when internal temperature control mechanisms are still undeveloped. In the few studies where nesting success has been monitored in tropical species, figures vary from 20% to 40%, while some high-Andean trochilids (*Oreotrochilus*, *Oxypogon*) are exceptional with success rates of around 60%. About 30% of nestling mortality in tropical species is attributable to predation, whereas adverse climatic conditions contribute to the majority of all losses. The reverse is the case in some North American trochilids (*Calypte*, *Archilochus*), where similarly low nesting success is known, except for the Broad-tailed Hum-

mingbird from the higher altitudes of the Rocky Mountains, with 60%. According to these studies predation accounts for most of the mortality during reproduction.

Female hummingbirds may occasionally be seen at nests with young that are not their own. Violet-ears (*Colibri*) have been reported to feed nestlings and fledglings of White-eared Hummingbirds and trainbearers (*Lesbia*). The Brazilian hummingbird specialist A. Ruschi observed, in his aviary, a female Planalto Hermit (*Phaethornis pretrei*) which adopted a nestling of the same species whose mother had died. However, normally females chase any visitor to their nest away.

At the age of 15-18 days, a few days before fledging, nestlings are much more active in the nest, and they will preen their plumage for extended periods and look around with interest when other birds or the parent are near the nest.

After leaving the nest the young are fed by the mother for 18-25 days, in some tropical genera like fairies and sylphs occasionally for up to a month. Juveniles do not follow their foraging parent but remain in a particular place for several days, often high up in the tree tops, where they are fed by the female. When they are flying well, often shortly after the fifth day after fledging, the female prolongs the feeding intervals, teaching the young by loud calls to come for food wherever she wants to feed them. By doing so the juveniles quickly learn to follow the parent bird to her feeding grounds in flowering shrubs, vines or trees. Foraging for nectar is the next step for the young to learn, and this is

Male hummingbirds are generally polygamous, associating with the females only briefly during the reproductive cycle and then only for the purpose of courtship and fertilization. This generally occurs in a short period of sexual synchronization wherein males advertise for mates by vocalizing and display their plumage to advantage. This sometimes entails gathering at communal or diffuse lekking grounds, as with the Phaethornithinae, but more frequently it involves prolonged and solitary calling from within territories to attract receptive females, which invest so much in parental care that they are choosy in their search for mates. The resultant competition between males for access to females selects for brilliant plumage and elaborate displays. The Frilled Coquette, for example, erects a rufous crest, fans a glittering emerald throat, and raises the mantle feathers to show off a white rump band, all to charm his prospective mate.

[*Lophornis magnificus*.

VIREO]

All parental duties, such as nest building, incubation and rearing of the young are carried out solely by females, like this Rufous Hummingbird collecting nest material from a bullrush. There are occasional reports of males assisting at the nest during the incubation or feeding stages, but most cases are probably due to misidentification. Nest building in hummingbirds generally takes between five and ten days, with most effort being invested during the morning, and very little after mid-afternoon. Females of this species, however, along with most other North American hummingbirds, tend to continue nest construction throughout the day. After initial completion, females regularly repair and add to nests through the breeding cycle.

[*Selasphorus rufus*,

mainly achieved by observing the adult at close quarters when she is sampling nectar. However, this period of learning to choose the right food is often based on trial and error. Several days before juveniles achieve independence they show mutual agonistic behaviour, often attacking each other with their feet, trying to prevent the brood-mate from being fed. Between feeding bouts, young hummingbirds are often seen to probe at twigs or red parts of leaves which resemble flowers in shape and colour. This exploratory behaviour is maintained throughout adolescence and ultimately leads them to new nectar sources.

Female hummingbirds may successfully rear two broods in a season, and in some North American species nest building and even incubation have been observed while the female was still attending nestlings in her first nest. For several tiny tropical species (*Chaetocercus*, *Lophornis*) one brood only seems likely to be the limit, for energetic reasons. Generally all species will attempt to nest a second or third time if their initial clutches or broods are lost at an early stage of reproduction.

Although the effort of reproduction causes severe physiological stress to adult females, their typical lifespan of 6-12 years seems to be similar to that of males, which of course play no part in nest building or rearing the young. The average maximum age of free-living trochilids seems to be about five to eight years. In the wild, one Blue-throated Hummingbird was known to be 12 years old, and a ringed Ruby-throated Hummingbird was trapped in the Rocky Mountains when aged 11 years, while captive birds have been known to live some years longer (see Relationship with Man). Although few data are available on the annual survival rate, information from North American species indicates a rate of between 40% and 50%.

Movements

Few members of the Trochilidae make substantial seasonal movements that could be called true migration. The species embarking on such journeys are those whose breeding grounds lie furthest north or south of the tropical zone, among them the world's smallest long-distance avian migrant, the Calliope Hummingbird (*Stellula calliope*). Many more species undertake post-breeding dispersal, altitudinal movements connected with food supply or

climate, or nomadic wandering in search of nectar sources. The hermits are generally less mobile than the trochilines.

In fact, very little is known about hummingbird movements; few species have been the objects of systematic ringing projects and most speculation remains based on data that are little more than first and last records at a given locality or regular appearance and disappearance in some area or another. Where they come from or go to, or in what age- or sex-classes they move are matters that are entirely unknown for the majority of species. Although long-distance migration by hummingbirds is rare, F. G. Stiles has pointed out that migratory or nomadic behaviour is more pronounced in nectarivorous birds than in those of virtually any other trophic category.

Since all hummingbirds depend on nectar throughout the year they must ensure that a ready supply of the appropriate flowering plants is available. Within the tropics this supply is year-round and constant, each species only having to find "its" food plants, and as a result the great majority of all tropical lowland trochilids are more or less sedentary. For montane species breeding at high elevations, this search for nectar-rich flowers and their associated tiny invertebrates can require a regular seasonal movement to lower altitudes, often to coastal regions. Surprisingly, some high-Andean species remain at the highest elevations throughout the year, as for example the hillstars (*Oreotrochilus*). They all breed at up to 4000 m or 5000 m, often right to the snow-line. Nests are typically sheltered by rocks or on buildings, while food plants include cacti, spiny shrubs and cushions, or *Puya*, a spiky bromeliad; they also need to take many arthropods. Some hillstars do move to lower altitudes but only in the severest conditions.

Little is known about the movements of hummingbirds nesting in the high southerly latitudes of South America. The Green-backed Firecrown, with a breeding range extending to Isla Grande of Tierra del Fuego at around 54° S, migrates northwards for the austral winter mainly to the lowlands of Argentina, reaching as far north as 23° S. The nominate race of the Giant Hummingbird, breeding in southern and central Chile and western Argentina, traverses the Andes to milder lowland Argentina in the autumn.

By contrast, there is a comparative wealth of information on the migration strategies of North American trochilids. Most migratory hummingbirds are partial migrants: only some of the population undertake movement, often those at the northern lim-

Most trochiline nests are tiny cup-shapes attached to branches or forked twigs, although pendular and domed structures are built by some species. Female trochilines tend to select breeding sites in the vicinity of prime foraging areas.

They visit appropriate sites, often hovering over them and perching on them repeatedly.

This Rufous-tailed Hummingbird has started the process of nest building at its chosen site in a low shrub by creating a platform of strong twigs, then adding softer material to form a cup. It nests practically all year round in much of its range from central Mexico to western Ecuador, except during the annual moult.

Seasonality of nesting is mediated by environment, those birds breeding at high altitudes or latitudes tending to be strongly seasonal while species from tropical lowlands often appear non-seasonal when local conditions allow. It has been found that nest architecture is a useful phylogenetic tool in the group as for the eleven trochiline groups proposed, nests show typical patterns for each assemblage.

Unfortunately, nest descriptions for several key taxa are not yet available, so further research is required.

[*Amazilia tzacatl*.
Photo: François Gohier/
Ardea]

When completed, the Purple-throated Carib's nest is small relative to the size of the bird, a soft compact cup of plant fibres woven with strips of bark, moss or lichen to camouflage the exterior. This species, like a few others, has an interesting resource-based mating system, in which females are allowed into male feeding territories that are otherwise rigorously defended, and they tend to mate with males that have appropriated the highest-quality resources, visiting these when feeding their young. The female herself is highly territorial around the nest-site, attacking much larger species that venture too close.

[*Eulampis jugularis*,
Le Lamentin, Martinique.

its of the breeding range, while others are sedentary. Among the species that vacate their entire breeding range in North America are the Ruby-throated, Black-chinned (*Archilochus alexandri*), Calliope and Rufous Hummingbirds.

On their autumn and spring journeys between southern Canada and the eastern USA and Central America many Ruby-throated Hummingbirds make an astonishing crossing of the Gulf of Mexico, a one-way trip of 800-1000 km. They appear to migrate in troops of varying sizes, travelling low above the water; A. C. Bent describes how in a high wind Ruby-throated Hummingbirds were observed flying between the waves of Lake Erie, and on another occasion about 8 m above the waters of the Gulf of Mexico. Males arrive first both in spring and autumn, followed by females then juveniles, with about a week between them all, a pattern also noted for other hummingbird species. Most birds however follow the coast of the USA and Mexico rather than crossing the Gulf. Arrival on the breeding grounds in the north in about early May is possibly timed to follow on the appearance of the migratory Yellow-bellied Sapsucker (*Sphyrapicus varius*), since the hummingbird can feed on the tree sap exposed by this woodpecker (see Food and Feeding), while arrival in Arkansas is said to be synchronized with the flowering of the dwarf buckeye shrub (*Aesculus parviflora*), a favourite nectar source. The timing of the autumn overland movement during August and September coincides with the peak occurrence of jewelweed (*Impatiens biflora*) flowers.

Some of these northern breeders show a loop migration pattern, following different autumn and spring routes when migrating. For the Calliope Hummingbird, between its breeding grounds in the western USA and south-west Canada and its winter quarters in south-west Mexico, these round-trip distances can be up to 4500 km and 5500 km respectively. On the basis of both ringing records and museum skins, movement in autumn appears to be principally along the Rocky Mountains, with the northbound spring movement further west and at a lower altitude, along the Pacific coast. A few ringing recoveries point to individuals following the same route each year. In contrast to the Ruby-throated, the Calliope Hummingbird seems to migrate singly and not in groups.

The Rufous Hummingbird breeds further north than any other member of the Trochilidae, at 61° N in Alaska. If the distance between this extreme point and the south of its wintering grounds in central Mexico is measured in body lengths, then this species holds the world record for the longest migration performed by any bird. It follows an elliptical route very similar to that of the Calliope Hummingbird: in July and August southwards along the Coast Ranges and Sierra Nevada in the west, and the Rocky Mountains further east (where it is common at nectar sources at up to 3000 m, exceptionally 4000 m), avoiding the Great Basin Desert between, with return migration from January following the Pacific coast to arrive in north-west North America around April. The species is present on its breeding grounds for one of the shortest periods recorded in the Trochilidae. The mean body

Various materials are used by hummingbirds in nest construction. After clinging to a suitable looking leaf-tip, a female hermit selects a nest-site upon which she attaches material to construct a cone-shaped nest. Depending on the strength and angle of the leaf, hermits, like this Straight-billed Hermit, often attach ballast, such as pieces of clay and pebbles, to maintain stability and ensure that the cup is horizontal. The nests of trochilines are often made of moss and plant fibres, as in the case of this Violet-headed Hummingbird, while an inner layer of small feathers, animal hair and other soft material forms an insulating lining. The entire structure is often bound together by spiders' webs, many species decorating the outer surface of their nests with material that functions as camouflage; this Ruby-throated Hummingbird (bottom left) has used lichen and bark for this purpose. Nests tend to be saddled on branches and forked twigs or placed on large leaves, although many different sites have been recorded. The nest of this Anna's Hummingbird, for example, is perched on top of a pine cone. The tendency of this species to nest during winter, the incubating female often being exposed to heavy frosts or snow, has probably developed to reduce competition with other hummingbirds that visit the coastal Californian scrub zone during spring to breed.

The White-necked Jacobin positions its nest on top of *Geonoma* palm fronds. When leaving the nest, females of this species perform a strange moth-like flight, with curious rising and falling movements. This is thought to relate to nest protection, possibly by drawing the attention of potential predators away from the nest-site itself. When predators are detected close to nests, hummingbirds mob them directly using dive-bombing flights accompanied by frantic distress calling.

[*Florisuga mellivora* *mellivora*, La Selva Biological Reserve, Costa Rica. Photo: G. I. Bernard/NHPA]

mass of trapped birds on spring migration was 3.27 g, in autumn 3.44 g, the most likely explanation for the difference being that birds cover the northward journey in shorter stages to avoid being earlier than the opening of their nectar flowers at any place *en route*. Birds have been recorded arriving in the state of Washington at the end of February, a time when the last stragglers are just leaving Mexico, and the advance birds must try to survive on aphids and midges. In Oregon, the arrival of the bulk of the birds is said to coincide with the blooming of the currant *Ribes sanguineum*.

Allen's Hummingbird also follows an elliptical flyway, southward through Arizona and central Mexico but in spring further to the west; the first birds begin to move south already in May, the earliest departure of any North American trochilid, while the last have left California by early October. Again, adult males migrate about two weeks before females and a month before juveniles. Arrival in Mexico is from August, some departing in January to establish territories by mid-February. Another likely loop migrant is the Broad-tailed Hummingbird, which breeds in the southern and central Rocky Mountains, most probably following the same elliptical south-east, west, north route to and from Mexico.

The energetic problems raised by the long-distance movements of these tiny birds, in particular the non-stop flight of the Ruby-throated Hummingbird across the Gulf of Mexico, remained something of a puzzle for many years. It used to be thought that this species had a metabolic rate in flight of 80 cm³ of oxygen per gram per hour, which meant that if they carried an extra 2 g of fat they would still only be able to cover a maximum of about 620 km and hence could not cross the Gulf. However, later experiments showed that the average metabolic rate was actually considerably lower at 42 cm³ of oxygen so that, flying at 40 km per hour, they would have energy reserves sufficient for about 25 hours of flight or a distance of 1000 km.

Like other migratory birds, trochilids have to accumulate body fat as an energy store in order to cover long distances without feeding. The Ruby-throated Hummingbirds taking the route across the Gulf of Mexico must double their body mass to around 6 g, while increases of up to 59% have been recorded for Broad-tailed Hummingbirds immediately before they set off southwards, and in Anna's Hummingbird a maximum body-mass increase of 48% in males and 44% in females has been measured in October.

Ring studies carried out in Brazil have shown that there are seasonal north-south movements within the tropics. Individuals of the Ruby Topaz (*Chrysolampis mosquitus*) marked in the state of Paraná were retrapped around 1000 km to the north-east; the species appears to leave the Rolândia region of Paraná in

April, during the austral autumn, returning annually on almost the same date in mid-October.

The two *Calypte* species, Anna's and Costa's Hummingbirds, illustrate well how difficult it can be to unravel hummingbird movements. Anna's breeds along the coastal region of California, leaving in about June-July. The birds either move the relatively short distance into the mountains behind, some to altitudes of over 3000 m, though when mountain temperatures drop in the autumn many return to lower elevations; or they cover the much greater distance to the south and east as far as northern Mexico and New Mexico. The two movements seem to be different: the first is a form of post-breeding altitudinal dispersal; the second is true migration. Winter site-fidelity has been noted in Arizona

Nests of the Phaethornithinae differ markedly from their trochiline relatives, lending weight to the morphological evidence for their separation at the subfamily level. The Reddish Hermit, like all members of the assemblage, constructs a pendant, compact, cone-shaped nest, most often attaching it to the inner tip of a hanging palm or Heliconia frond, but sometimes fastening it to a vertical root or twig, if suitably sheltered. Unlike trochilines, hermits tend not to nest in the proximity of rich feeding patches. This species, one of the smallest birds in the world, has been reported using a wide variety of materials in nest construction.

[*Phaethornis ruber ruber*, Montsinéry, French Guiana. Photo: Jany Sauvenet/NHPA]

Very few nests of the Green-backed Firecrown have been described, but the species is known to prefer sites that overhang water and to build the small cup typical of most trochilines. This design is at least occasionally draped in impressive amounts of extraneous material for the purposes of camouflage. Balanced microclimatic conditions, such as temperature and humidity, are apparently essential to the successful development of hummingbird embryos, and, for this reason, nests are usually placed out of direct sunlight or adjacent to waterfalls. The breeding season of this species falls between September and December in the austral spring, as its breeding range is otherwise beset by very low temperatures.

[*Sephanoides sephaniodes*, southern Chile.
Photo: Günter Ziesler]

with ringed individuals being trapped in subsequent years. Anna's Hummingbird has been described as having no winter range as such and its migration is rather a series of temporary residences wherever flowers or feeders are available.

Costa's Hummingbird is a bird of desert and other dry places, with three principal breeding habitats in the USA and three different migration strategies. Almost all of those breeding about March-April in the Sonoran Desert scrub of Arizona and California depart in summer, males a month or so earlier than females and immatures. They appear to move to the coast of California and north-west Mexico, though this is not easy to ascertain because of the resident population already present in the region. The migrants return to their breeding grounds in October and November when the desert lavender *Hyptis emoryi* (Labiatae) starts to flower. In contrast, the birds inhabiting the desert scrub of California, Nevada, Utah and Arizona undertake post-breeding movements around June, some to higher elevations in the coniferous forests of the eastern Mojave Desert but most apparently southward to Mexico. In the coastal scrub and chaparral of southern California breeding birds are present between March and September. There is an increase in numbers in late April, possibly from the Sonoran Desert population, some of which conceivably arrive to breed for a second time. Many spend the winter in gardens but most presumably leave for Mexico. Post-breeding vagrancy has been recorded north to southern Canada and to eastern Texas.

Other ringing studies have shown varying degrees of site-fidelity within the Trochilidae to both breeding and wintering grounds. Of 188 male Magnificent Hummingbirds ringed on their breeding grounds in Arizona, 41% returned in subsequent years, as did 23% of 60 females ringed. Of 1224 Ruby-throated Hummingbirds, 130 (39 males, 91 females) were retrapped, while none of those ringed in winter in Louisiana was subsequently recovered, though in Costa Rica 2 of 14 ringed there were later recaptured. That the birds can also closely follow the same flyways is shown by the 96 male and 161 female Anna's Hummingbirds trapped on autumn migration in south-east Arizona: 35.4% and 23.8% of them respectively had been captured there in the preceding two years. In the Broad-tailed Hummingbird, up to 56% of females and 29% of males ringed as adults in summer subsequently returned, though only up to 22% of 146 birds ringed as

juveniles turned up again at their natal sites. Twenty Rufous Hummingbirds were retrapped up to four years after ringing at the same winter sites in Mexico.

Ringing work has also thrown light on the sorts of distances individual hummingbirds will cover within their home ranges. In their breeding quarters, males of course move around searching not only for food but also for females. In Costa Rica, marked individuals of a number of species moved distances of approximately 0.5-1.5 km to defend feeding territories at flowering trees and plants in peak bloom between February and August. One male Violet-headed Hummingbird was recorded in two consecutive years moving from a *Stachytarpheta* (Verbenaceae) shrub to a *Warszewiczia* (Rubiaceae) tree when it was in full flower then back again, and a male Fork-tailed Woodnymph (*Thalurania furcata*) moved about 1.5 km in three days to a richer stand of the same *Heliconia imbricata*. In the Rocky Mountains in summer, Broad-tailed Hummingbirds were recaptured at up to 6.7 km away from their release points. Between March and July in Arizona more than 100 male Magnificent Hummingbirds were marked but only a few were noted again, showing a high degree of mobility. In contrast, 12 Rufous Hummingbirds were recaptured at the same wintering site in Jalisco, Mexico, after an average of 32 days, indicating only short-distance foraging movements. In Brazil, a ringed Black Jacobin traversed an elevational difference of 455 m and a distance of 30 km inside a day while searching for nectar sources.

Also in Brazil, displacement experiments by A. Ruschi have shown that many hummingbird species have a strong navigational ability, which is perhaps not altogether surprising, since, being entirely dependent on particular flowers, they must know where to find them within their feeding areas. Ringed individuals of the Planalto Hermit, Black Jacobin and Black-throated Mango (*Anthracothorax nigricollis*) were transported 85 km to the coast then released; all of them returned to where they had been trapped, at an altitude of 700 m, the hermit covering the distance in just two and a half hours! By contrast, other ringed individuals of the Minute Hermit (*Phaethornis idaliae*), Frilled Coquette and Brazilian Ruby (*Clytolaema rubricauda*) were unable to find their way back from a distance greater than 15 km.

Much of our picture of trochilid movements has been constructed from casual observations of species appearing in an area for a period of time at regular intervals, generally coinciding with the flowering of particular plants. The Horned Sungem (*Heliactin bilophia*) is among the most nomadic of the central Brazilian hummingbirds. It is a bird of open *cerrado* and scrubland and has recently colonized parts of the country where the forest has been cleared. It becomes very much commoner in the Distrito Federal between March and May because this is the peak flowering time there for Verbenaceae and Labiatae, *Hyptis* in particular. Nevertheless, some individuals are observed there outside this period, indicating the existence of resident and migrant populations. The Black Jacobin is present in Rolândia from March to September (hence its local name of "winter hummingbird"), but a little further north, in Rio de Janeiro State, the species is absent in the winter, generally appearing only in October. In São Paulo, there is a considerable hummingbird influx in March and April, when *Eucalyptus* blooms, most birds departing again during the austral winter. In Costa Rica, the White-necked Jacobin disappears from inland sites on the Caribbean slope between August and the end of November, but simultaneously becomes commoner at the coast. Marking programmes are necessary to confirm that individuals are actually moving from one place to another.

Near the Pacific coast of central Mexico researchers found that a feeding guild of 21 hummingbirds was composed of three broad groups, each with a different foraging strategy involving movement of differing types: one consisted of resident birds, each species or genus using its own particular habitat all year round; a second was made up of nomadic species, each utilizing several habitats, wandering from one to another, tracking the flowering of food plants; and the third was of migratory species, present in the area solely in winter. The resident species were territorial, defending their nectar sources, and the nomadic species were trappiners, while the migrants were also territorial, though since the food plants "left over" for them by the other two groups provided a rather scant diet they also took many insects.

Nests of montane trochilines are often bulky structures of moss and lichen, held together with spiders' webs and placed in sheltered positions under tussocks or against rocks. Those that nest at altitudes up to 5000 m, such as the Andean Hillstar, attempt to control microclimatic conditions by building highly insulated nests in windless positions. The large, woolly nests of this species are often glued to sheltered rock surfaces, especially in caves where several females may nest semi-colonially. The hillstars are the only group of hummingbirds in which territorial roles are reversed, the female performing the territory defence.

[*Oreotrochilus estella bolivianus*, Lauca National Park, Chile.
Photo: A. de Sostoa & X. Ferrer]

The Giant Hummingbird often simplifies nest protection by breeding in cacti, where sharp spines deter all but the most stubborn of terrestrial predators. The structure is composed of moss and lichens, lined with animal and plant wool, and is generally built in very open situations, often at the top of a cactus.

This aggressively territorial species is, as its name suggests, the largest member of the family. It is swift-like in size and flight action, travelling rapidly through the air using unusually slow beats interspersed with short glides. It is not uncommon throughout its pan-Andean range, usually frequenting open habitats with low vegetation. It gathers in particular at flowering Agave plants and Opuntia cacti for foraging, at which time it usually clings to the food plant in preference to hovering, presumably because its size imposes energetic constraints. It also visits exotic flowers in gardens and occurs regularly in the parks of major Andean cities, such as Quito.

The complexity of hummingbirds' movements at a single location harbouring many species was vividly shown in a two-year study carried out at a site 1000 m up in pre-montane rainforest on the Caribbean slope of Costa Rica. Out of a total of 22 hummingbird species, a core group of 14 was examined in detail, ten of which were resident and four non-resident. The peak in total numbers was roughly from November to the end of July, followed immediately by the yearly population low point between August

and October, caused by a gap between the departure of visitors and the return of birds known or suspected to breed in the study area. November to March was the peak breeding period. There was a partial or complete downslope emigration from the area by residents mainly between June and September. For example, Coppery-headed Emeralds (*Elvira cupreiceps*) and White-bellied Mountain-gems (*Lampornis hemileucus*) descended to around 500 m, while Brown Violet-ears and Green Thorntails went down almost to sea-level, as did some immature Green Hermits, though during the period December-April. Non-altitudinal displacement was also observed, for instance the Green-fronted Brilliant (*Heliodoxa jacula*) was absent during June-July, probably visiting food plants outside the study area, namely *Heliconia latispatha* growing by nearby rivers. The non-resident birds appeared mainly in June-July early in the rainy season. They had apparently just bred elsewhere or were immatures; their immigration into the area seemed to coincide with the flowering of the shrub *Cephaelis elata* (Rubiaceae). Three of them, the Violet Sabrewing (*Campylopterus hemileucurus*), Green Violet-ear and Variable Mountain-gem (*Lampornis castaneiventris*) arrived from a higher altitude, while the Purple-crowned Woodnymph (*Thalurania colombica*) came from lower down the slope. Perhaps contrary to expectation, the peak flowering season at this site did not coincide with maximum breeding activity and the relationship between the two appears complex. The strongest correlation was for the Green-fronted Lancebill: the staggered flowering of five epiphytic shrubs, mainly Ericaceae, used as nectar-sources, generally coincided with important phases of the lancebill's annual cycle. A similar relationship seemed to exist between the Green Hermit and *Heliconia*, and the White-tipped Sicklebill and *Centropogon granulatus* (Campanulaceae), since the bird's appearance in the study area was associated with its blooming.

At a site on the same slope but at around 100 m above sea-level, the two peaks in flowering intensity, one in the dry season and the other in the first half of the wet, coincided with hummingbird breeding and moult respectively. The second of these is an especially critical time since the young have just fledged and a good supply of nectar is crucial. This abundance of flowering is succeeded by a low point in nectar availability from November to the end of January, when many trochilids leave the area, visitors from upslope as well as breeders. Observations in

This Western Long-tailed Hermit has attached its nest to a banana leaf, constructing it mainly from plant fibres and cobwebs, and placing it in the leaf tip position typical of the Phaethornithinae.

In common with most other members of this subfamily, the female faces the leaf while incubating so that her tail points out of the open side of the nest.

One advantage of this nest design is that the overhanging leaf provides excellent protection from rain. Furthermore, the nest material allows free passage of water and quickly dries. These aspects are important, as showers are frequent and often torrential in the hermit's rainforest habitat.

Females tend to start incubating irregularly after the first egg is laid, but they sit almost constantly once the second has arrived. Incubation itself lasts anything between 14 and 23 days, although most hummingbird eggs take 16-19 days to hatch. Incubating females compensate for a reduced food intake during incubation by lowering their body temperature, which results in an energy saving of around 50% per day. Although males have very little to do with the nesting process, this incubating Green-backed Firecrown was being investigated by a male.

[*Sephanoides sephaniodes*,
southern Chile.
Photo: Günter Ziesler]

The Black-chinned Hummingbird, like all members of the family, lays two eggs that are glossy white and oval in shape. Depending on the timing of laying, eggs might hatch almost simultaneously, or, as in this case, asynchronously, with a gap of up to 48 hours before the second egg hatches. The first stage of nestling growth lasts about five days.

During this time the nestlings are practically naked apart from two dorsal rows of neossophtile down about 5 mm long. Their eyes are still closed and they remain almost inactive in the nest. When the female arrives at the nest she touches one of the nestlings behind its eye-bulges with her bill, in response to which the nestling gapes and is fed.

these months of hummingbirds feeding at nectar-poor flowers highlight the difficulties faced by some species.

If a range of habitats within a particular area cannot ensure a reliable nectar supply at different times of the year then hummingbirds are forced either to move to where there is nectar or to adapt their annual cycle to the rise and fall of its abundance. Their varied and complex movements are in the main the result of hummingbirds maximizing their chances of access to nectar at different energy-demanding stages of their annual cycle, such as breeding and moult, but given the vagaries of climate short-distance movements by hummingbirds will often prove to be unpredictable.

Relationship with Man

Man's attitude to hummingbirds is a very unusual one within the context of his relations with the whole of the Animal Kingdom: it is wholly characterized by positive emotions, such as aesthetic admiration, affection and general amazement. As far as is known, hummingbirds have nowhere given cause for the degree of wanton persecution suffered by some other bird families: they are not crop pests; they do not compete with or harm domestic animals; they are not noisy; and there is not much eating on them, although, surprisingly, there is a south Brazilian dish called *passarinhos com polenta* with hummingbird as the chief ingredient! Apart from adding to the sum of human pleasure, they also carry out the important service of pollinating many of man's food plants, some of which have co-evolved with the birds; at least 58 plant families are pollinated by trochilids in Brazil alone, chief among them being the Bromeliaceae.

The persecution to which they have been subjected is rooted in their virtues. Since the earliest times they have been killed for their wonderful plumage, and more recently captured in huge numbers so that people can appreciate them even more at close quarters. Mankind has doubtless always been astonished by their unearthly iridescent colours, their acrobatic flying skills, and their sheer tininess. They are among the most mysterious creatures on our planet.

Our feelings towards these birds are well expressed in the names we have given them. Their English names parallel both those in other languages and the normally unpoetic scientific

nomenclature in attempting to capture some of the hummingbird magic: sapphire, emerald, goldenthrout, mountain-gem, jewelfront, brilliant, hillstar, sunbeam, starfrontlet, sunangel, woodstar, sungem, sylph, woodnymph and fairy. The Spanish name is *picaflor* (peck the flower), the Portuguese *beija flor* (kiss the flower). That trochilids are easily attracted to the vicinity of houses by garden flowers or feeding bottles containing sugar-water, and quickly become accustomed to people, only increases their attractiveness.

Native peoples throughout South America use hummingbird plumage in their adornment, and we can assume that they always have done. The esteem in which these minute glittering feathers were, and are, held is exemplified by the fact that the great ceremonial head-dress of the Aztec king Montezuma (Moctezuma) II, the main element of which is the long green uppertail-coverts of the Resplendent Quetzal (*Pharomachrus mocinno*), the sacred bird of the Maya and Aztecs, also contains many hundreds of trochilid feathers, interspersed with tiny platelets of gold. The Aztecs kept hummingbirds and other animals in special extensive zoos in order to have a supply of feathers and pelts for ceremonial purposes. In 1519 King Montezuma presented this royal symbol to his eventual conqueror, Hernán Cortés, who in turn gave it to Emperor Charles V as part of a fabulous Aztec treasure of gold, silver, jade, pearl and turquoise. After seeing this hoard in Brussels, the artist Albrecht Dürer wrote "I have never seen anything in my entire life that filled my heart with greater delight". The treasure can be seen today in the Museum für Völkerkunde in Vienna.

Huitzilopochtli, "hummingbird of the south", from "*huitzilin*" (hummingbird) and "*pochtli*" (southern), was actually one of the most powerful of the Aztec gods, associated with battle and human sacrifice, the bird being depicted actually feeding on the blood of sacrificial victims. Fallen warriors were metamorphosed into hummingbirds to accompany the sun on its daily journey for four years before returning to earth to feed on nectar for eternity. Huitzilopochtli had another special place in Aztec mythology as the bird which guided the people on their long trek southwards in search of a new homeland to the spot in present-day Mexico City where they built their capital Tenochtitlán.

The greatest of the gods, the feathered serpent Quetzalcoatl, wore a cape of trochilid feathers and a head adornment of flowers with hovering, feeding hummingbirds. The first ruler of the

Unlike hummingbird chicks raised in dome-shaped nests, such as sylphs and metaltails, those raised in open-topped nests do not beg vocally for food. These Western Long-billed Hermit chicks in Amazonian rainforest gape to receive food, but they do not produce the familiar begging calls of most birds. After the first stage of nestling development, the female uses a non-tactile method to induce gaping: she fans the dorsal down of chicks while she hovers. Until they are thus stimulated they remain motionless, even if their parent perches on the side of the nest.

[*Phaethornis longirostris baroni*,
Manu National Park, Peru.

unified Aztec kingdom was called Huitzilihuite, or "hummingbird feather", and during his reign in 1391-1415 he elevated Huitzilopochtli to the position of Sun God, the supreme power in the pantheon, a further member of which was the goddess of earthly pleasures, beauty and birth, Xochiquetzal, or "flower bird", and she too was symbolized by a hummingbird. Trochilid feathers were an important part of a bride's wedding dress in Mexico into modern times. The bird was also an integral part of the Aztec calendar. This is more important than it might appear because this highly complex system lay at the very heart of Aztec culture and cosmology. Representations of hummingbirds in stone can be seen throughout the Aztec archaeological sites. The hummingbird is present too in the mythology and artefacts of the South American peoples, particularly the Inca and Nazca of the Andes, but to a much lesser degree than in Mesoamerica. Some of the gigantic figures inscribed by the Nazca on the surface of the dry plateaux of Peru probably represent hummingbirds.

A multitude of stories has arisen from the fact that trochilids often appear with the rains, since the flowers bloom then, but of course they are credited in many legends, particularly in the dry south-west of the USA, with being rain bringers, so water vessels are commonly decorated with their image. The Hopi and Zuni peoples incorporate the hummingbird in their rain dances, and their inlaid jewellery of turquoise and silver features the birds as favourite motifs. In a Navajo legend, the first hummingbird was large, white and very greedy, so much so that it killed many flowers in its search for ever more food. The Creator was displeased and made the bird smaller and smaller to reduce its appetite, but in the process it also lost its song, whereupon the other birds in their pity asked the Creator to compensate the hummingbird with the most beautiful plumage of all, which he duly did.

Another Maya version of how the hummingbird Tzunum (clearly an onomatopoeic name) came by his colours tells how, although the bird originally had inconspicuous plumage, his whole pride was in his fantastic flying skills. However, on his wedding day he realized that his dull feathers were an inappropriate outfit and he was thrown into depression. The other birds saved the day by giving him fragments of their own plumage as wedding presents, which so moved him that he almost lost his voice. The Great Spirit was touched by the hummingbird's gratitude and allowed him to wear his nuptial splendour for all time.

A different Maya legend relates how there were tiny scraps of material left over after the Great Spirit had created all the birds. Not wishing to throw them away he used them to make a hummingbird pair, which thus came to be composed of all the colours. The sun too wished to make a contribution so he gave his light, and since then hummingbird feathers have shone and glittered.

A belief in the special position of trochilids survives today in the form of superstition and folk medicine. On the whole hummingbirds, and also their nests, are regarded as bringers of good luck. In Costa Rica, dried and perfumed nests are hung around the neck, on belts, or nowadays in cars, as lucky talismans. In Mexico, amulets containing mummified or powdered hummingbirds can be bought in markets to bring good luck or success in love. The life-long fidelity of an unwitting partner can be secured by boiling up a dried hummingbird, including feathers, in a soup or stew, or by sprinkling the ashes of a hummingbird heart

The female Blue-tailed Emerald, like most hummingbirds, inserts her bill into the nestling's gape, regurgitating a fine mixture of nectar and arthropods. Hummingbird chicks take 23-26 days to fledge, although this is increased in high-Andean species to 30-40 days, as the low temperatures delay development. Females generally visit the nest twice every hour and brood the young for the first 7-12 days, after which time the nestlings can regulate their own body temperatures.

[*Chlorostilbon mellisugus*,
Ecuador.
Photo: F. Köster/Ardea]

Between days six and nine after hatching, there is an intermediate stage of development during which the main feather tracts grow but the dorsal down is retained. By this time, the eyes of these

Rufous-tailed

Hummingbird nestlings have opened and they sit more alertly in the nest. Although they no longer require direct touching to induce gaping, the feeding process is basically the same: the adult's bill is inserted deeply into the gape of her offspring before transference of food. Hummingbird chicks are fed frequently and grow rapidly, reaching almost 80% of their adult mass within 10-12 days.

This species is common in a broad variety of habitats including the edges of humid forest, coffee and banana plantations, scrub and gardens, ranging between sea-level and 1200 m from Costa Rica and Panama, south to western Ecuador.

Its relative success is at least partly explained by its generalist foraging strategy and its pugnacity. Individuals can feed on many different species of flowering plant, tolerating native and exotic species alike, while any hummingbird, *Hesperiidae* butterfly or euglossine bee that strays onto a territory is likely to be attacked in flight.

[*Amazilia tzacatl tzacatl*, Belize.]

Photo: Michael Gore]

on the head of the object of desire; similar effects can be achieved by presenting him or her with soap containing trochilid extracts. Evil spirits can be pacified by constructing a little altar with candles before the body of a hummingbird wrapped in red twine.

One of the traditional methods of capturing trochilids still in use is the employment of a long, flexible fishing rod-like tool, six or eight metres in length, with a blob of sticky lime at the end. This is carefully lowered on to the back of the bird as it hovers before a blossom, sticking it fast to the end of the rod. Native peoples have also used clay pellets shot from blowpipes to stun hummingbirds.

In the European and North American fashion markets, the breathtaking beauty of trochilid plumage quickly became a very desirable article. In the second half of the nineteenth century millions of hummingbird skins were exported from Central and South America, not only to decorate ladies' hats and clothes but also for the manufacture of feather pictures, ornaments, and artificial flowers. The collection of mounted specimens was promoted by the naturalist Adolphe Boucard as an interesting and appropriate hobby for ladies: "It is as beautiful and much more varied than a collection of precious stones, and costs much less....quite the thing for all those who have money, taste and leisure." In London in 1888, 12,000 trochilid skins were sold in one month; at one sale there 37,603 hummingbird skins from South America and Trinidad were auctioned; a single delivery from a Brazilian port contained 3000 Ruby Topaz skins; 152,000 hummingbirds were sold by one auction house in London between 1904 and 1911, and in 1905, some 8000 were used to make a single shawl. Already in 1851 E. J. Silva Maia of the National Museum in Rio de Janeiro was warning that some species had disappeared in the area purely as a result of trapping for the fashion industry. Some species were probably hunted to extinction in this slaughter since a few were first described from such skins but never subsequently seen, although the hybridization between species, and even genera, frequently reported for trochilids (see Systematics) would perhaps be responsible for some of these forms.

Ever since the first reports of brilliant, minute, nectar-feeding birds reached Europe in the sixteenth and seventeenth centuries people have wanted to be able to have them in captivity in order to study them closely, an activity virtually impossible in

their native habitats. In the year of the Great Exhibition, 1851, John Gould displayed 1500 mounted hummingbirds in the London Zoological Gardens, attracting 75,000 spectators, among them Queen Victoria. However, learning how to keep a bird with such unusual dietary requirements alive on the long journey across the Atlantic took some time. It was soon discovered that small insects or spiders had to be supplied along with the usual diluted honey or dissolved sugar. Both John Latham and Gould brought hummingbirds to England around the middle of the nineteenth century, but the birds died soon after arrival. In 1876, a collection of 50 trochilids belonging to six species could be seen in Paris, and two were admired in Hamburg three years later. The first hummingbird in London Zoo, a Sparkling Violet-ear, arrived in November 1905, but was dead fourteen days later. Trochilids drew huge crowds wherever they were shown, but no European zoo was able to emulate New York, where one bird remained alive for ten years. Eventually, the arrival of air transport put an end to the severe losses experienced in transit by ship.

A long process of trial and error has been necessary to arrive at the correct formula for artificial nectar, the best all-purpose liquid being a variable mixture of glucose, fructose and saccharose diluted in water to a concentration of around 10%. The protein element in the diet can be more problematic since it varies from species to species; lowland species are said to be "less sensitive" than those from uplands, which can quickly become ill on liquid protein supplements. Proteins obtained ultimately from mammals seem to give poorer results than those from hen's eggs or mashed mealworms, where a regular supply of live arthropods proves difficult. But finding the right balance is still a delicate business; too much remains unknown about the trochilid digestive system. Even zoos regard 5-10% of birds being alive after two years as a success, although private aviculturalists can sometimes achieve survival rates of around 50%. Captive birds can live on average for about ten years, and an age of 17 years has been recorded.

Learning the technique of breeding hummingbirds in captivity has taken even longer than discovering how to provide them with the diet they need. The first success in a zoological garden was in Cleveland, Ohio, with a Red-billed Streamertail pair in 1959, and in 1977 the same species was also the first to breed in a European zoo, at Wuppertal, Germany. About one-third of the roughly 80 species kept in captivity have attempted to breed but

These Blue-throated Goldentail chicks have entered the third stage of nestling development, which begins around day 10 and lasts until fledging. During this period, although their rectrices and remiges are still rather short, the chicks are almost completely feathered and they lose their dorsal down. By this time, they completely fill the tiny nest cup, which in this species has a characteristically incurved rim that expands slightly to accommodate them.

[*Hylocharis eliciae eliciae*, Costa Rica.
Photo: Michael & Patricia Fogden]

The Ruby-throated Hummingbird, and several other hummingbird species that visit the Nearctic to breed, exploit the superabundance of resources during the temperate summer, and then migrate, often long distances, to spend the winter in warmer, more southerly latitudes. These nestlings are almost fully grown and are nearly ready to leave the nest.

[*Archilochus colubris*, Illinois, USA.

only around 20 have successfully done so worldwide since the 1950's. The birds' needs are best met in a large aviary with permanent water for bathing in the form of a shower, a fountain or soaking vegetation, while ample plant cover is also necessary for the hummingbirds to be able to conceal themselves in. A major difficulty in trying to encourage the birds to breed is that since they have no pair-bond they will not even attempt to breed unless they are able to execute their courtship displays. Another

problem often encountered is the well-known aggressive behaviour of trochilids; in the past, these pugnacious tendencies were countered by putting so many into one aviary that they were unable to hold territories, but it soon became clear that a few species would dominate the others, causing them physical harm and monopolizing the food sources. Another common mistake has been to keep some species in temperatures that were too high for them; upland species often require a cool environment. The

A few days before making their first flight, chicks become much more active, regularly perching on the side of the nest, preening and exercising their wings. Relatively few nestlings survive until fledging, this figure varying at around 20-40% for tropical species, while some high-altitude breeders such as the Andean genera *Oreotrochilus* and *Oxygogon*, and the Broad-tailed Hummingbird of the Rocky Mountains, have around 60% success rates. About 30% of nestling mortality in tropical hummingbirds is attributed to predation, and the immobility and silence of the nestlings of such species is clearly aimed at minimizing predation.

[*Selasphorus platycercus*, Wyoming, USA.

The fact that hummingbirds will visit human habitations to sip artificially provided sugar solutions, as illustrated by this Broad-billed Hummingbird, has recently increased their popularity. Hummingbird feeding is popular in North America, and is becoming more so in the Neotropics. On the other hand, our admiration for them has occasionally led to a certain amount of persecution. Their iridescent plumage decorates the traditional ceremonial costume of tribal peoples, and was once extremely fashionable in Europe and North America. Birds are still trapped today to supply the avicultural trade.

ideal enclosure is thought to be a greenhouse full of plants with an adjoining open-air aviary. Disease can also cause high mortality, the commonest probably being mycosis, in particular various fungal infections of the respiratory passages.

Confronted with the task of describing hummingbirds, the ornithologist's first impulse on lifting the pen is often of a literary, almost poetic nature. Georges-Louis Leclerc, Comte de Buffon, the great eighteenth century naturalist, thought them "of all animated beings...the most elegant in form and brilliant in colour. The stones and metals polished by art are not comparable to this gem of nature. She has placed it in the order of birds, but among the tiniest of the race...she has loaded it with all the gifts of which she has only given other birds a share". A generation later John James Audubon described the hummingbird as a "glittering fragment of the rainbow...a lovely little creature moving on humming winglets through the air, suspended as if by magic in it, flitting from one flower to another, with motions as graceful as they are light and airy, pursuing its course and yielding new delights whenever it is seen". The final word should perhaps be left to one who was a poet before he was a birdman, the so-called Father of American Ornithology, Alexander Wilson, who was forced to leave his home in Paisley, Scotland, during the Napoleonic Wars, because of his revolutionary verses:

"What heavenly tints in mingling radiance fly!
Each rapid movement gives a different dye;
Like scales of burnished gold they dazzling show -
Now sink to shade, now like a furnace glow!"

Status and Conservation

Since 1987 all members of the Trochilidae have been placed on Appendix II of the Washington Convention on International Trade in Endangered Species (CITES). This means that their conservation status gives sufficient cause for concern that trade in live birds is regulated and is not allowed without a permit. In any case, virtually all countries with populations of trochilids have prohibited the export of live birds, so permit applications are rarely granted. Those birds most at risk are in Appendix I of the Convention, which forbids any trade at all involving them,

but at present the only hummingbird thus protected is the Hook-billed Hermit.

Although trochilids breed overwhelmingly in the Neotropics, a part of the globe where habitat destruction is widespread, intensive and continuous, most particularly in lowland rainforest where the giant trees preferred by loggers are easiest to extract, their situation is not as dramatically bad as that of many other Central and South American bird families. There are various reasons for this. Their nesting sites are generally in the lowest forest strata, and their minute nests can be built virtually anywhere where there is a large overhanging leaf, a cavity among tree roots, an overhang, or a low shrub. Also, where forest is cleared flowering plants may appear, albeit perhaps briefly, supplying the birds with adequate food, and even crop plantations like banana or coffee are not entirely hostile environments for some species. In addition, the relative paucity in lowland rainforest of those families of flowering plants preferred by trochilids, when compared to montane forest, shrubby habitats, ravines, *páramo* and other grasslands means that these lowland forests, in contrast to the Andes, have never been a stronghold of hummingbird diversity.

As an illustration, 163 trochilid species have been recorded in Ecuador, 135 in Colombia, and 100 in Peru, many species occurring in more than one of these countries, while Brazil, with an area of more than twice the total of these three countries together, supports a far more modest 84. The highest numbers of hummingbirds per unit area are found in the small Central American states.

An Endemic Bird Area is defined by BirdLife International as an area encompassing the overlapping breeding ranges of 2 or more restricted-range species such that their complete ranges fall inside its boundaries; restricted-range species are landbirds with a total natural breeding range estimated at less than 50,000 km². In their survey of the 20 countries in the world with the highest number of EBA's, eight are of vital importance for hummingbirds with four of them among the top five countries, the fifth being Indonesia. In all, there are 128 restricted-range trochilids, 39% of the 328 species recognized herein. The numbers of restricted-range trochilids in each of these eight countries, with the number of globally threatened hummingbird species endemic to each country in brackets, are: Colombia 37 (5); Peru 26 (4); Ecuador 22 (4); Venezuela 22 (3); Mexico 16 (4); Brazil 10 (1);

Hummingbirds have been less severely affected by deforestation than many other groups, partly because most species are not strictly reliant on primary forest. In fact, rainforest is unusually poor in hummingbird species due to the paucity of suitable flowering plants. They usually forage and nest in lower strata, tolerating fairly serious habitat degradation, indeed often actually benefiting from it, as clearings entail an increase in forest edge and flowering plants.

The Violet-chested Hummingbird occupies a restricted range in north-west Venezuela, but is not considered threatened as it survives well in secondary growth and plantations.

[*Sternoclyta cyanopectus*,
El Limón, Venezuela.
Photo: Luis Mazariegos]

Bolivia 7 (0); and Chile 2 (1). It should be noted that the sum of the restricted-range species appears greater than 128 since they may occur in more than one country. The total of globally threatened hummingbirds in these important EBA countries is 22, a very substantial fraction of the 27 classed as globally threatened throughout the Americas by BirdLife International; a further 22 species are placed in the Near-threatened category.

Of the 27 globally threatened hummingbirds, eight are classed as Critically Endangered, seven as Endangered, and twelve more as Vulnerable. However, one of BirdLife's eight Critically Endangered hummingbirds, the Bogota Sunangel, may not be a valid species or, if it is, may already be extinct. Equally, the so-called Tachira Emerald (*Amazilia Polyerata distans*), listed by BirdLife as Endangered, is almost certainly a hybrid between the Glittering-throated Emerald and the White-chinned Sapphire. Thus, for the present purposes, the numbers in these classes fall to seven and six respectively, and the total to 25. Population and status trends for birds like hummingbirds are more or less impossible to discern except over long time periods. Consequently between the first collation of all available information published in 1992 and the latest in 1998, only a very few species have been placed in different categories: the Hoary Puffleg has now been classed as Near-threatened rather than Vulnerable/Rare; the Neblina Metaltail is also now considered Near-threatened instead of Rare; and both the Tooth-billed and Beautiful Hummingbirds (*Calothorax pulcher*) have been removed from the Near-threatened category.

If we look at the situation of the seven trochilids in the Critically Endangered category more closely it should provide us with some case-studies of the various factors which, alone or especially in combination, can threaten the existence of a species.

The Hook-billed Hermit is now restricted to lowland Atlantic forests in eastern Brazil in the states of Bahia and Espírito Santo. There are estimated to be around 50-250 individuals remaining in highly fragmented and scattered remnants of the original habitat covering an area of perhaps less than 100 km²; its original range may once have been as large as 35,000 km². Its perilous situation is reflected by the fact that it is the only trochilid on Appendix I of CITES. This part of Brazil is densely populated and the influx of people continues unabated, so roads, settlements and agriculture, in the form of coffee, banana and rubber

plantations, are constantly eating into the forest. Other threats are logging and mining. Within the Brazilian part of the Atlantic Forest Lowlands EBA there are 51 Key Areas for birds, many of them with some sort of protected status, though resources are inadequate to implement conservation requirements. Illegal squatters, deliberately started or poorly controlled fires, road construction and so on continue to degrade protected areas, including even national parks. However the true status of this bird remains somewhat obscure, and additional hope for its future can be gained from the fact that five new bird species have been found in the general region in the last ten years, while others thought extinct have been rediscovered. Further exploration could conceivably reveal further populations of this hummingbird.

Of the 328 species of hummingbird currently recognized, some 128 (39%) occupy ranges estimated at less than 50,000 km². One of these is the Napo Sabrewing, a Near-threatened species which is apparently dependent on relatively intact forests in the Ecuadorian and Peruvian Andes. Like many hummingbirds it is very poorly known and until more data are collected detailing the habitat preferences, movements and threats of such species it is difficult to judge their conservation status accurately.

[*Campylopterus villaviscensio*,
Orito, Putumayo,
Colombia.
Photo: Luis Mazariegos]

The Sapphire-bellied Hummingbird is found only in and around small areas of mangrove forest on the north Colombian coast; all breeding individuals are apparently in a single population which could amount to less than 50 birds. Huge tracts of this rare habitat have been destroyed by urbanization and pollution which continue to threaten the remaining fragments. A new road and pipeline across the Isla de Salamanca National Park have altered tidal and river flows, leading to increased water salinity levels and the eradication of large areas of mangrove. This hummingbird species is severely threatened by a fatal combination of elements: a very small and probably declining population; a restricted habitat; and damaging human impact. Apart from the Isla de Salamanca National Park (21,000 ha), the hummingbird is protected within the Ciénaga Grande de Santa Marta Sanctuary (23,000 ha), but the areas of mangroves there have also suffered damage.

A hummingbird endemic to dry valleys in xeric scrub and thorn forest in the interior of northern Honduras is the Honduran Emerald (*Polyerata luciae*). It occurs at only a few locations and, although common at some of them, its range is extremely restricted and further population decline is likely. Until 1950 it was known from only 11 specimens but in 1988 it was found to be a common resident in the Aguán Valley. The principal threats are habitat destruction through the creation of pasture for cattle, pineapple plantations, and roads. The species can, however, tolerate a certain level of habitat alteration and has been observed feeding in heavily grazed understorey, but unless other populations are discovered it remains under very severe threat.

The Scissor-tailed Hummingbird (*Hylonympha macrocerca*) is endemic to the cloudforests of north-east Venezuela, occurring at around 1000 m. Although it is locally common, its entire range is encompassed by the Paria Peninsula National Park, the core area on the mountain of Cerro Humo being just around 15 km². Even within this nominally protected national park threats remain, chiefly in the form of agricultural encroachment, including burning to clear land, but also general human disturbance, road building, and so on. Once again the crucial combination of low numbers and a small, declining range has put this bird in the class Critically Endangered.

The Juan Fernandez Firecrown faces an even more complex series of threats. The species is restricted to the Juan Fernández

Islands in the south-eastern Pacific, 680-800 km west of Chile, an important centre of biodiversity; indeed, 98 of the 142 flowering plants recorded there are endemic to the islands. One race, *leyboldi*, is probably already extinct. It was confined to the island of Alejandro Selkirk (85 km²), and was last recorded in 1908, though some authorities hold that gene flow between the islands is likely and that the race may not have been valid anyway. The nominate race is present on the 93 km² island of Robinson Crusoe, where there are thought to be around 250-400 individuals. It is estimated that the entire population of the species in the archipelago in the nineteenth century could have been as high as 20,000 birds. The main conservation problems here are posed by introduced species, both plants and animals. Settlers have over the centuries brought with them dogs (now absent), cats, rats, mice, cattle, sheep, goats, rabbits and coatis (*Nasua nasua*). Only about 10% of the area of Robinson Crusoe retains its native vegetation of evergreen trees, tree ferns, ferns and the like. The Juan Fernandez Firecrown also faces competition from its congener, the Green-backed Firecrown, first noted on the larger island in 1830. The Green-backed copes much better with the non-native vegetation, since they are both of recent mainland origin, and there are now estimated to be around 5000 Green-backed Firecrowns on Robinson Crusoe. One of the principal threats from an introduced plant is posed by the bramble *Rubus ulmifolius*; apparently only the smaller female of the Juan Fernandez Firecrown, as well as both sexes of the Green-backed Firecrown, feed on its flowers. The islands have been a national park since 1935, a biosphere reserve since 1977, and have been nominated for the status of World Heritage Site. A US\$2,500,000 restoration programme by the Chilean government is at present under way; the survival of the Juan Fernandez Firecrown depends on its success.

The Black-breasted Puffleg (*Eriocnemis nigrivestis*) is found only in stunted elfin forest with páramo on mountain crests in north-west Ecuador, at altitudes of around 2500-4500 m, and is today possibly confined to a single peak, the volcano Pichincha, where three birds were seen in 1993, the first ones for 13 years. Its numbers in the past can be judged by the fact that over 100 skins can be found in museums. This puffleg is thought to be close to extinction, perhaps with a single population of below 50 birds, having declined because of habitat destruction for cattle

The Blossomcrown is endemic to Colombia, where it occupies a rather restricted range, within which it is generally rare, although locally abundant in parts of the Santa Marta Mountains. It occurs in humid forests and older stands of second growth, but is not known to tolerate major habitat degradation. It is not considered to be at immediate risk, but is classed as Near-threatened, implying that its status requires further investigation and monitoring.

[*Anthocephala floriceps floriceps*, Santa Marta, Colombia. Photo: Luis Mazariegos]

There is no evidence that the Hooded Visorbearer can withstand any degradation to its arid open-country habitat within its very small, entirely Brazilian, range. However, the remoteness and inhospitable nature of its favoured localities suggest that environmental damage, in the form of human population growth or agricultural expansion, is unlikely to be severe in the short term. It is thus currently treated as Near-threatened.

grazing, potato growing and charcoal making. However a concerted effort is being made by local and international conservationists to have its range protected. Since this is very close to the capital, Quito, much use is being made of press and television publicity. During the main part of the flowering season, in the rains between November and February, the Black-breasted Puffleg occurs at elevations of 3100-4500 m, when it most likely breeds in the humid elfin forest and *páramo*, spending the rest of the year in temperate forest at around 2400 m. This Critically Endangered hummingbird has one advantage in that it is apparently more of a generalist feeder than some others, and although its movements are particularly dependent on the flowering of *Fuchsia* and *Ericaceae* it seems that it will accept a wider range of food plants than was once thought. A crucial aspect of the threat facing the species is that it is an altitudinal migrant. This illustrates the important principle that it profits a montane species little if part of its range is declared a reserve while another habitat, upslope or downslope of the protected area and equally important for its survival, continues to be laid waste. For such birds a small protected area covering a large altitudinal range can be far more valuable than an extensive one spread over a single altitude. Ideally, similar considerations should also apply to long-distance migratory species to safeguard food supplies along the flyway between breeding and winter quarters.

The final hummingbird in the Critically Endangered category is another puffleg endemic to northern Ecuador, the Turquoise-throated Puffleg. It is known from a single locality in the arid ravine of the Río Guailabamba at 2100-2300 m in Pichincha Province, and could actually already be extinct. This locality is the only one named on the six museum skins in existence and is where the type specimen was taken in 1850. The forest of this area has been almost wholly cleared so unless new populations are found, perhaps in quite different habitats or even in southern Colombia, then the outlook for this species looks decidedly bleak.

If we briefly examine the reasons for placing some of the remaining 18 species in the IUCN categories Endangered and Vulnerable, the same overall pattern of threats emerges. All six of the species classed as Endangered occur in forest that is being cleared for cultivation, timber exploitation or settlements. Three of them are Mexican endemics, the Short-crested Coquette (*Lophornis brachylophus*), Oaxaca Hummingbird (*Eupherusa cyanophrys*) and

White-tailed Hummingbird (*Eupherusa poliocerca*), and all three inhabit the deciduous, semi-deciduous and montane evergreen forests and forest edges of the Sierra Madre del Sur EBA in the states of Guerrero and Oaxaca. This area is undergoing rapid deforestation, and the most pessimistic observers even suggest that it could be virtually cleared within the next few years. The low-altitude zones are being felled to make way for citrus fruits, maize and coffee, the cloudforest cleared for coffee plantations, while the oak,

The Black-thighed Puffleg is a poorly known species restricted to the Northern Central Andes EBA, where it is generally uncommon, occurring in humid forest borders and bushy pastures and preferring open vegetation. Given its small range and population, its survival would be of considerable concern if it relied on pristine habitats. However, it has adapted successfully to man-modified environments such as gardens and parks, and is therefore currently classed as Near-threatened.

[*Eriocnemis derbyi*,
Caldas, central Andes
of Colombia.

Photo: Luis Mazariegos]

Although previously considered Vulnerable, the Hoary Puffleg has been found to be more widespread than originally suspected. It is at least partially reliant on the presence of intact humid cloudforest along the Pacific slope of Colombia and Ecuador, and this habitat is rapidly disappearing. Nevertheless, healthy populations have been found in several protected areas such as La Planada Reserve in southern Colombia. After re-evaluation, its status has been adjusted to Near-threatened, although effective protection of relevant reserves remains vital.

[*Haplophaedia lugens*, La Planada Reserve, Nariño, Colombia.
Photo: Luis Mazariegos]

fir and pine trees above 1800 m are being taken as timber. Apparently only the White-tailed Hummingbird enjoys any degree of protection, since some of its range lies within Omiltemi State Ecological Park. This has an area of 96 km², while the entire EBA covers 12,000 km². All three of these trochilids are said to be locally common but have very restricted ranges, the Oaxaca Hummingbird in particular.

Another pair of sympatric Endangered congeners are the Little (*Chaetocercus bombus*) and Esmeraldas Woodstars (*Chaetocercus berlepschi*) of western Ecuador. They are found in one of the most threatened forest types in the Neotropics, namely moist evergreen forest. The Little has a much greater range than the Esmeraldas, extending into Peru, but there are few modern records of either species. The remaining hummingbird in this category, the Chestnut-bellied Hummingbird (*Amazilia castaneiventris*) from the eastern Andes of Colombia, is threatened as much by its small numbers as by habitat destruction. Rapid and extensive deforestation is widespread throughout the area, even inside sanctuaries, compounded by the apparent rarity of the species; there has been only a single record of the species in the last 30 years.

The threats faced by the twelve Vulnerable species vary little from the preceding cases. Forest habitat destruction poses the greatest risk to the survival of the majority of them. The Mexican Woodnymph (*Thalurania ridgwayi*), Black Inca (*Coeligena prunellei*), Royal Sunangel and Violet-throated Metaltail (*Metallura baroni*) are all considered locally common in parts of their ranges, but habitat fragmentation puts these populations under great pressure, and once below a critical level recovery is impossible without rigorous conservation measures. Protection is however rare and seldom effective. The Black Inca was once one of the most numerous of the so-called "Bogotá trade skins" but it is now restricted to a few cloudforest patches. Species perhaps less threatened by current habitat destruction than by critically small populations and/or restricted ranges, usually as a result of past human interference, are the Purple-backed Sunbeam (*Aglaeactis aliciae*), Colourful Puffleg, Grey-bellied Comet (*Taphrotesia griseiventris*), Marvellous Spatuletail, Chilean Woodstar and Glow-throated Hummingbird (*Selasphorus ardens*). The final two species in this class are the White-tailed Sabrewing (*Campylopterus curvipennis*) and the Mangrove Hummingbird. The population of the former on the island of Tobago

is still recovering from the devastation wrought by Hurricane Flora in 1963, thanks partly to an active conservation programme, an unusual instance of a hummingbird population put at risk by natural causes, though exacerbated by anthropogenic factors; the latter is severely threatened by clearance of mangroves on the Pacific coast of Costa Rica for salt-pans and shrimp ponds.

Only two of these 25 globally threatened hummingbirds do not at least partly inhabit forest or woodland of one type or an-

Few ecological data are available on the Pink-throated Brilliant, a restricted-range species of the foothills of the eastern Andes that seems to be uncommon and perhaps poorly adapted to utilize man-modified habitats. Humid forest within its range is still relatively extensive, but is under threat of clearance if current rates of destruction are maintained. The species is classed as Near-threatened, which highlights the importance of protecting areas of suitable habitat for this species and others largely or wholly restricted to the same area.

[*Heliodoxa gularis*, Serranía de los Churumbelos, Cauca, Colombia.
Photo: Luis Mazariegos]

The Colorful Puffleg is only known from wet subtropical forest in the vicinity of Chagwayaco, on the Pacific slope of the Andes in south-west Colombia. Like many other hummingbirds, its fate is ultimately tied to that of the forests it inhabits. With such a restricted range in an area where deforestation may be increasing, this species is classified as Vulnerable. Its future largely depends on the effective protection of the Munchique National Park, in which it has been found, and probably also the nearby Los Tambitos Nature Reserve.

[*Eriocnemis mirabilis*,
Cauca, Colombia.

other: the Purple-backed Sunbeam, of scrub; and the Chilean Woodstar, of scrub, desert and agricultural areas. Indeed, of all 128 BirdLife International Restricted-range species, only nine are independent of forests. Many trochilids specializing in páramo grasslands, arid areas, scrubby thickets and so on face threats from habitat destruction for cattle raising or cultivation, but they possibly tend to be more adaptable, taking to secondary growth, plantations and gardens more readily than do true forest species. Those hummingbirds inhabiting high-altitude Andean páramo or puna and bordering stunted forest types, such as the hillstars (*Oreotrochilus*), the metalltails (*Metallura*) and the thornbills (*Chalcostigma*), face a lower risk because these rather inhospitable regions are in the main subject to relatively less human interference. The main threat in this zone is to the *Polylepis*-woodland ecosystem at around 3500-4500 m, as this is cleared to make way for subsistence cultivation and livestock, and there is much burning to create grazing; it is also plundered for firewood. However, of course, the primary factor affecting the family overall is that montane humid tropical and subtropical forests, the home of the majority of trochilids, continue to be destroyed at a hopelessly unsustainable rate.

The single hummingbird currently listed as Data-deficient, the Coppery Thorntail, has not been seen this century and is known solely from three nineteenth century museum specimens from Bolivia. It is probably the least known of all currently accepted trochilid species, although there is no argument over its status as a species; this seems destined to be an advantage of purely academic significance, as it is very possibly extinct already.

Only one hummingbird species is definitely known to be extinct, Brace's Emerald, from New Providence Island in the Bahamas. Although the taxon is known only from a single male taken in July 1877, it is quite likely to be a good species and not, as previously thought, a possible race of the Cuban Emerald (*Chlorostilbon ricordii*), also present in the islands though not on New Providence itself. Because the type locality was called into question all Bahaman *Chlorostilbon* were named *C. ricordii bracei*, until recent closer examination of the holotype, and the correspondence surrounding its collection, showed that the form should almost certainly be accorded species status. The collector himself shot two further individuals, both females, but he misidentified them and they were subsequently shown to be

Bahama Woodstars, providing an object lesson in the difficulties involved in attempting to ascertain the status of rare Trochilidae. Even when the holotype was taken the species must have been rare, and was probably restricted to scrubby thickets around the town of Nassau. No individual was ever seen again, but whether the cause of its extinction was primarily human interference or climate change remains obscure. Fossil remains appear to indicate that another trochilid no longer extant once inhabited New Providence.

The Bogota Sunangel was recently described from a single specimen bought in Bogotá in 1909, though properly examined only in the late 1940's, and it is thought to have come from the eastern or central Andes of Colombia, a region where much of the forest has been cleared for crops like potatoes, coffee and maize. It may still exist in the cloudforest at around 1400-2200 m, and would presumably be a relict species with a very restricted range. However, there is also the possibility that it could be a hybrid, in the same way that many of the Bogotá trade skins have proved to be. Some workers consider it to be a hybrid between Long-tailed Sylph (*Aglaiocercus kingi*) and the Fork-tailed Woodnymph, others that it is between the former and the Purple-backed Thornbill, or that one of the parents belonged to the genus *Heliangelus*. On the basis of this uncertainty the form is probably best not treated as a good species for the time being, although the case for its being so has certainly been well made. If it is a species and has disappeared it would be the first known extinction of a trochilid species in South America, though the great taxonomic uncertainty surrounding many forms known only from the odd trade skin leaves many questions in the air. Where the forests remain pristine there are still good hummingbird populations, showing that deforestation rather than nineteenth century collecting is responsible for the drastic reduction in range and numbers of many species.

The Trochilidae of North America provide some examples of low-level threats at present unlikely to have major effects on whole populations. The huge number of feeders placed by people in their gardens to attract hummingbirds can also have certain negative effects, doubtless outweighed, however, by the population and range increases that both feeders and garden flowers have made possible. The birds can come to depend on artificial feeding when food plants are not flowering, early or late in the season, and thus populations may be maintained at an un-

Only two of the 25 hummingbird species considered threatened do not inhabit forests at all. One of these is the Chilean Woodstar, a little-known species of scrub, desert and agricultural areas. Although these habitats are not immediately threatened, the species is treated as Vulnerable primarily because of its tiny range, in south Peru and north Chile. While it is probably relatively secure, its small populations are susceptible to collapse, and competition with the dominant Peruvian Sheartail (*Thaumastura cora*), a recent colonist, could prove detrimental to breeding and foraging success. It has usually been placed in monotypic *Eulidia*, but its morphology suggests it belongs in *Myrtis*.

[*Myrtis yarrellii*, Arica, northern Chile.
Photo: Luiz Claudio Marigo]

naturally high level. Sudden cold weather, disease (not uncommonly spread by contaminated feeders), monopoly of feeders by dominant species, predation by cats, and even hypothermia from too cold sugar-water taken while perched are all recorded causes of death, though no species is thereby threatened.

Birds such as Magnificent and Calliope Hummingbirds can be adversely affected by forest fires and tree-felling in their breeding range but this is generally a temporary setback. Conversely,

the forest clearings thereby created often provide perfect conditions for many of the food plants required by hummingbirds.

Probably the main conservation concern in North American trochilids centres on Costa's Hummingbird. The dry, scrubby places it inhabits in the south-western USA are threatened by residential development, and clearance for cattle grazing. Introduced South African buffelgrass grown for cattle is susceptible to fire, which destroys hummingbird food plants and nesting trees when it spreads

The rarely photographed Scissor-tailed Hummingbird is endemic to damp, mossy mid-altitude cloudforests of north-eastern Venezuela. Its range is very small and its habitat is disappearing rapidly, prompting its listing as Critically Endangered. The core area of suitable habitat on the Cerro Humo amounts to only 15 km². Even in this officially protected area within the Paria Peninsula National Park, agricultural encroachment and human disturbance are degrading the remaining forest. Note the marked sexual dimorphism.

[*Hylonympha macrocerca*, Cerro Humo, Paria Peninsula, Venezuela.

Right photo: Josep del Hoyo/Lynx]

The Juan Fernandez Firecrown, endemic to its namesake islands in the south-eastern Pacific, is now restricted to a single island, where 250-400 birds are thought to survive. In comparison, 5000 individuals of its mainland relative, the Green-backed Firecrown (*Sephanoides sephanioides*), a recent colonist and competitor, also live on the island. Introduced cats, rats and coatis (*Nasua nasua*) have increased predation rates, while cattle, sheep, goats and rabbits have drastically altered the local environment, as have humans, so that only 10% of the island's area now retains native vegetation. A huge conservation programme aims to repair the island's devastated ecology, and the future of this Critically Endangered species depends on its outcome.

[*Sephanoides fernandensis*, Juan Fernández Islands, Chile.
Photo: Roland Seitre/Bios]

to the desert scrub. While fire in the species' other main habitat, chaparral, is part of a natural cycle and can benefit the bird, this is not so in the desert. Another threat faced by this species is that Anna's Hummingbird dominates at feeders and exotic garden plants in the new settlements built within its range.

Anna's Hummingbird has increased its range considerably since the 1930's, now reaching north up into British Columbia, when in the past the San Francisco area was its northern limit; it is also now found east to Arizona. Introduced plants like *Eucalyptus*, flowering when native ones do not, mean that the species remains in southern California after breeding instead of dispersing farther afield as before. Study areas with exotic flowering plants support 2-3 times more Anna's Hummingbirds than plots with only indigenous species.

The Ruby-throated Hummingbird has been shown to be absent within its nesting habitat in Nova Scotia where herbicides are used in forestry practice, apparently because of a lack of successional growth rather than poisoning. However, that this can endanger trochilids is reported from Brazil, where H. Sick described how hummingbirds "die by hundreds and thousands" in pineapple plantations due to excessive pesticide application.

Now that killing for plumage is firmly in the past, hummingbirds face no special threats directed specifically at them. They are difficult birds to keep and only relatively few specialists are interested in them for the aviary trade. Their fate is tied to that of countless other animal and plant species in the Neotropics, if rampant deforestation is allowed to continue at its current rate. The world will unquestionably be a poorer place if the tragic list of extinctions is to include more hummingbirds.

Subfamily PHAETHORNITHINAE

Genus *RAMPHODON* Lesson, 1830

1. Saw-billed Hermit

Ramphodon naevius

French: Colibri tacheté German: Sägeschnabel-Schattenkolibri Spanish: Ermitaño Picosierra

Taxonomy. *Trochilus naevius* Dumont, 1818, Mount Corcovado, Rio de Janeiro, Brazil. Sometimes considered more closely related to genus *Androdon*, and placed in Trochilinae, but most morphological characters link it to hermits, in particular to genera *Eutoxeres*, *Glaucis* and *Threnetes*. Genus often considered to include *Glaucis dohrnii*. Description of race *freitasi* did not consider intraspecific variation related to age and sex. Monotypic.

Distribution. SE Brazil (S Minas Gerais and Espírito Santo to Santa Catarina; also recorded in Rio Grande do Sul).

Descriptive notes. 14-16 cm; 5.3-8.5 g. A large hummingbird; with *Eutoxeres*, one of the three heaviest hermits. Easily distinguishable from *Androdon aequatorialis*, the only other hummingbird with prominent saw-like serration of the mandibles, and, in adult male, a hooked tip to the upper mandible, by rufous-ochraceous throat with dark gular stripe. Bill almost straight. Male larger than female, with longer wings and tail, broader central rectrices and more contrasting coloration of underparts. Female has bill shorter, slightly decurved, and without hooked tip. Immature similar to adults, but with pale fringing to feathers of upperparts.

Habitat. Understorey of humid littoral forest up to 500 m.

Food and Feeding. Nectar of long-tubed flowers with steady-state blooming; recorded at *Justicia*, *Aechmea*, *Billbergia*, *Neoregelia*, *Nidularium*, *Quesnelia*, *Vriesea*, *Costus*, *Dahlstedtia*, *Erythrina*, *Nematanthus*, *Heliconia*, *Centropogon*, *Psychotria* and others. Small arthropods are mostly gleaned from vegetation. Like other hermit hummingbirds it is a trap-lining plant visitor, but it behaves aggressively over its feeding routes, excluding conspecifics as well as other hummingbirds.

Breeding. Gonadal activity indicates breeding Jul and Sept (São Paulo). Nest is loosely constructed, cone-shaped cup of plant material and cobwebs, attached to the underside tip of a long, pendent leaf. No further information.

Movements. No reliable information available. Presumably sedentary.

Status and Conservation. Not globally threatened. CITES II. Currently considered Near-threatened. Restricted-range species; present in Atlantic Forest Lowlands EBA. At least locally common, but habitat destruction may be a threat in future. Single record from Rio Grande do Sul, dating back to 1930.

Bibliography. Aleixo & Galetti (1997), Araujo *et al.* (1994), Belton (1984), Fischer (1994), Forrester (1993), Franco & Buzato (1992), Grantsau (1988), Guix *et al.* (1992), Hinkelmann & Schuchmann (1997), Hofling & Lencioni (1992), Oniki (1996), Pacheco (1997), Parker & Goerck (1997), do Rosário (1996), Ruschi (1978b, 1981-1982, 1986), Sazima *et al.* (1995), Scott & Brooke (1985), Selander (1966), Sick (1993, 1997), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Tobias *et al.* (1993), Vielliard (1994), Willis (1992), Willis & Oniki (1981).

Genus *EUTOXERES* Reichenbach, 1849

2. White-tipped Sickbill

Eutoxeres aquila

French: Bec-en-faucille aigle German: Weißkehl-Sichelschnabel Spanish: Picozoh Coliverde
Other common names: White/Bronze/Brown-tailed/Common Sickbill

Taxonomy. *Trochilus Aquila* Bourcier, 1847, Bogotá, Colombia.

Populations of E Panama and W Colombia sometimes separated as race *munda*, but morphological differences are based on a zone of character introgression between races *salvini* and *heterura*. Three subspecies normally recognized.

Subspecies and Distribution.

E. a. salvini Gould, 1868 - Costa Rica to W Colombia.

E. a. heterura Gould, 1868 - W Andes from SW Colombia to W Ecuador.

E. a. aquila (Bourcier, 1847) - E Andes from Colombia to N Peru.

Descriptive notes. 12-14 cm; male 10-12.5 g, female 8-10 g. Sickbills are unmistakable among all hummingbirds by their very strongly decurved bills. A large hermit hummingbird with dark green upperparts, dark green crown and nape, black and white streaked underparts, and dark (green and brown) rectrices with white tips. Female has shorter wing than male. Immature has light tips to remiges (mostly secondaries), and narrower rectrices than adult. Differences between races slight: nominate has the most prominent white tips to the rectrices and the most intensive orange-ochraceous edges to the undertail-coverts; adult male *heterura* has almost no white at the tips of the outer rectrices, and *salvini* tends to have lighter edging on undertail-coverts than other races.

Habitat. Understorey of humid and wet forest, older second growth, forest edge, near rivers, often in, or close to, *Heliconia* patches. Regularly between 300 and 700 m in Costa Rica, but recorded to sea-level as well as to 2100 m in Costa Rica and Colombia.

Food and Feeding. Nectar of *Heliconia* and *Centropogon* species with tubular blossoms similar in curved shape to bill, and small arthropods. Defends feeding flowers against other sickbills. Unlike most other hummingbirds, sickbills perch when feeding (recorded at *Heliconia* blossoms where this is possible).

Breeding. Jan-May in Costa Rica; data on gonadal condition indicate Mar and Jun in Panama, Aug in Colombia, Jun in Ecuador, and Sept in Peru. Nest is a loosely woven cup of plant materials (fibres, rootlets, etc.) attached by cobweb to the underside tip of a long, hanging leaf. 2 eggs; incubation 16-17 days, by female; chick black with grey down; fledging 22-25 days.

Movements. Sedentary; perhaps seasonal movements in some regions of Panama.

Status and Conservation. Not globally threatened. CITES II. Common throughout most of its range except the upper Magdalena Valley. Present in Braulio Carrillo National Park (Costa Rica); Río Nambi Reserve (S Colombia); and at Buenaventura (Piñas) and Tinalandia (Ecuador). In the lower Anchicaya Valley, near Buenaventura, SW Colombia, recorded density of at least 3-4 pairs/km².

Bibliography. Barnes *et al.* (1997), Blake (1989), Bloch *et al.* (1991), Fjeldsá & Krabbe (1990), Fogden (1993), Gill (1987), Hartert (1922), Hilty & Brown (1986), Hinkelmann (1985), Hinkelmann & Schuchmann (1997), Meyer de Schauensee (1949), Norton (1965), Remsen, Stiles & Scott (1986), Ridgely & Gwynne (1989), Ruschi (1961e, 1973b), Rutgers & Norris (1972), Salaman (1996), Slud (1964, 1980), Snow (1981), Stein (1992), Stiles (1975, 1979, 1980, 1985b, 1995b), Stiles & Skutch (1989), Stotz *et al.* (1996), Vigle (1982), Wetmore (1968a), Williams & Tobias (1994), Zimmer (1950b).

3. Buff-tailed Sickbill

Eutoxeres condamini

French: Bec-en-faucille de La Condamine

Spanish: Picozoh Colicanela

German: Rotschwanz-Sichelschnabel

Other common names: Rufous-tailed Sickbill

Taxonomy. *Trochilus Condamini* Bourcier, 1851, Archidona, Ecuador.

Races not well-separated geographically, forming a character introgression zone in N Peru. Taxonomic treatment of southernmost populations is under review. Two subspecies recognized.

Subspecies and Distribution.

E. c. condamini (Bourcier, 1851) - E Andes from SE Colombia to N Peru.

E. c. gracilis Berlepsch & Stolzmann, 1902 - E Andes of Peru and NW Bolivia.

Descriptive notes. 13-15 cm; male 10-12.5 g, female 8-10 g. A large hermit hummingbird, similar to *E. aquila* but with buffish outer tail feathers with white tips, blue patches on both sides of nape, and, in adult, mid-crown stripe bare of feathers. Female has shorter wings than male. Immature has light tips to remiges (mostly secondaries), narrower rectrices than adult, smaller blue nape patch and lacks unfeathered central line on the crown. Birds of race *gracilis* have shorter bill, and less distinct tailward extended belly streaking.

Habitat. Similar to *E. aquila*, but, particularly where common, from SE Colombia to N Peru.

more often in open, cultivated, or disturbed areas such as plantations, mossy forest, swamp forest, wooded ravines, near streams as well as in bamboo. Recorded between 180 and 3300 m in Peru.

Food and Feeding. Nectar (recorded at flowers of *Heliconia* and *Centropogon*) and small arthropods. Feeding by trap-lining confirmed, although presumably "feeding flowers as well."

Breeding. Season undetermined, but data on gonadal activity indicate Sept-Nov in Peru. Nest similar to that of *E. aquila*. 2 eggs; incubation 16-18 days, by female; chick black with grey down; fledging 22-24 days. First breeding in second year.

Movements. No reliable information available, presumably sedentary.

Status and Conservation. Not globally threatened. CITES II. Locally common along ravines and rivers with semi-open secondary growth and *Heliconia* stands. Very abundant in disturbed Andean foothills of the Rio Napo area of E Ecuador, with density of at least 3-5 pairs/km² recorded.

Bibliography. Best *et al.* (1997), Butler (1979), Cardiff & Remsen (1981a), Fjeldsá & Krabbe (1990), González (1998), Hilty & Brown (1986), Hinkelmann (1985), Hinkelmann & Schuchmann (1997), Meyer de Schauensee (1949), Norton (1965), Parker *et al.* (1982), Remsen & T aylor (1989), Remsen, Stiles & Scott (1986), Rutgers & Norris (1972), Salaman & Mazariegos (1998b), Snow (1981), Stotz *et al.* (1996), Terborgh *et al.* (1984), Zimmer (1930, 1950b).

Genus *GLAUCIS* Boie, 1831

4. Hook-billed Hermit

Glaucis dohrnii

French: Colibri de Dohrn

Spanish: Ermitaño de Espíritu Santo

German: Bronzeschwanz-Schattenkolibri

Taxonomy. *Trochilus dohrnii* Bourcier and Mulsant, 1852, Ecuador; error = Rio de Janeiro.

On following pages: 5. Hairy Hermit (*Glaucis hirsuta*); 6. Bronzy Hermit (*Glaucis aenea*); 7. Band-tailed Barbthroat (*Threnetes ruckeri*); 8. Pale-tailed Barbthroat (*Threnetes niger*); 9. Broad-tipped Hermit (*Anopetia gouellei*); 10. White-whiskered Hermit (*Phaethornis yaruqui*); 11. Green Hermit (*Phaethornis guy*); 12. White-bearded Hermit (*Phaethornis hispidus*); 13. Western Long-tailed Hermit (*Phaethornis longirostris*); 14. Eastern Long-tailed Hermit (*Phaethornis superciliosus*).

Often considered to belong to genus *Ramphodon*, but morphological characters clearly indicate placement in *Glaucis*. Monotypic.

Distribution. SE Brazil (Bahia and Espírito Santo).

Descriptive notes. c. 12-13 cm; male 6-8 g, female 5.5-7 g. A medium-sized hermit hummingbird similar to female *G. hirsuta*, i.e. with uniform ochraceous orange underparts, though with an almost straight bill and no rufous tail coloration. Adult male with some serration on edge of both mandibles. Female has shorter, more curved bill, shorter wings, narrower central rectrices, and is somewhat paler than male. Immature undescribed.

Habitat. Understorey of lowland (below 500 m) primary forest, littoral forest, mainly in damp areas along streams, particularly in areas with abundant *Heliconia* plants.

Food and Feeding. Nectar and small arthropods. Rare observations indicate feeding at same flowers as *G. hirsuta*. Feeds by trap-lining.

Breeding. Sept to Feb. Available information points to a nest construction similar to *Ramphodon naevius* or *G. hirsuta*. 2 eggs; incubation at least 15 days, by female; fledging 20-27 days.

Movements. No precise information available. Presumably sedentary, although sparsity of records at particular sites might reflect movements of some sort.

Status and Conservation. CRITICALLY ENDANGERED. CITES I. Restricted-range species: present in Atlantic Forest Lowlands EBA. Has declined greatly due to habitat loss, with overall range now reduced from perhaps c. 35,000 km² to possibly under 100 km²; total numbers now estimated at only c. 50-250 birds. Occurs at only a few widely scattered localities, possibly now only Porto Seguro Reserve and Pau Brasil Ecological Station in Bahia, and Linhares Reserve in Espírito Santo; at the last of these, only a single recent record despite presence of many observers; Córrego Grande Federal Biological Reserve (Espírito Santo) formerly thought to be a stronghold of the species, but now almost certainly extinct there. Nevertheless, true status remains uncertain, and further populations of the species might still survive. Main problem is continuing encroachment on habitat for settlement, mining and logging, with concomitant agriculture, fires and road building. See page 529.

Bibliography. Bernardes *et al.* (1990), Collar (1987), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Gonzaga *et al.* (1987, 1988), Grantsau (1988), Hinkelmann & Schuchmann (1997), King (1978/79), Knox & Walters (1994), Oniki (1996), Pinto (1935), Ruschi (1961g, 1965d, 1967b, 1969, 1974, 1976b, 1981-1982, 1982a, 1986), Sargeant (1996), Sick (1969, 1972, 1993, 1997), Sick & Teixeira (1979), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Wege & Long (1995).

5. Hairy Hermit

Glaucis hirsuta

French: Ermite hirsute **German:** Rotschwanz-Schattenkolibri **Spanish:** Ermitaño Hirsuto
Other common names: Rufous-breasted Hermit

Taxonomy. *Trochilus hirsutus* J. F. Gmelin, 1788, north-eastern Brazil.

Sister species of *G. aenea*, and these two often considered conspecific, but they meet in W Panama and W Colombia without interbreeding; present species interrupts former probably continuous distribution of *G. aenea* and presumably in gradual process of replacing it. Several attempts have been made to subdivide present species into races, with *affinis* of the Guianas, *mazeppa* of CE Brazil, and *abrawaya* of SE Brazil; these were based on plumage differences in immature and adult males and females, but did not take into consideration intraspecific variation in coloration and measurements independent of geography; only birds from Grenada, Trinidad and Tobago are morphologically separable. Includes "*Threnetes grizeki*", based on immature male plumage. Two subspecies currently recognized.

Subspecies and Distribution.

G. h. insularum Hellmayr & von Seilern-Aspang, 1913 - Grenada, Trinidad and Tobago.

G. h. hirsuta (J. F. Gmelin, 1788) - Panama, Colombia W of the Andes, and E of the Andes S to C Bolivia, and through Venezuela to the Guianas and almost all of Brazil.

Descriptive notes. 10-12 cm; male 6-8 g, female 5.5-7.5 g. A medium-sized hermit with dark green upperparts, brownish-rufous underparts, slightly decurved bill and the four outer rectrices rufous with broad black subterminal bands and white tips. Female has distinctly paler throat and upper breast; shorter wings and tail; narrower rectrices; bill more decurved. Male has serrated edges on both mandibles, female only on upper mandible; male sometimes has a somewhat hooked tip to upper mandible. Immature has feathers of upperparts ochraceous, and pale tips to remiges; narrower rectrices; immature male

has some prominent dark throat feathers resembling throat coloration in *Threnetes*. Race *insularum* has significantly longer wings and more decurved bill.

Habitat. Understorey of many types of forest and dense vegetation outside primary forest: second growth, woodland clearings, disturbed and secondary forest, riverine habitats, swamps, shrubs, forest edge, partly deciduous forest, bamboo thickets, gallery forest, islands of trees or shrub in grassland, *cerrado* and plantations. Recorded from sea-level to 1800 m, though mostly below 1000 m; possibly up to 3500 m in Venezuela.

Food and Feeding. Nectar of *Heliconia*, *Centropogon*, *Pachystachys*, *Passiflora*, *Trichanthera* and *Costus* species, as well as small arthropods.

Breeding. Jan-Jul on Trinidad, Apr-Jul in Panama. Sept-May in Brazil. Nest records in Sept in SE Colombia; Dec and May in N Colombia; Jun in E Colombia; Sept, Nov and Dec in Surinam; Feb, Mar, Jul, Aug and Dec in French Guiana. Data on gonadal activity indicate Feb in Venezuela; Feb and Jun in Colombia; Aug in Panama; Jan, Aug and Sept in Peru; Aug-Sept in Brazil. Nest built on underside of pendant leaf, a cone-shaped cup loosely constructed of plant strands decorated with lichens and plant matter, similar to nests of *Ramphodon naevius* and *Eutoxeres*; eggs partly visible from the outside. In contrast to most other hummingbirds, males recorded in immediate nest area, and reported to defend nest. Normally 2 eggs; higher clutch sizes are due to conspecific females laying in the same nest. Incubation 17-19 days, by female; chick black with grey down; fledging 20-25 days; young remain with female for 3-4 weeks. First breeding in second year.

Movements. No reliable information available. Presumably sedentary.

Status and Conservation. Not globally threatened. CITES II. Generally common throughout much of its extensive range, especially in Amazonia; the most commonly netted hummingbird species at Amacayacu National Park (SE Colombia). Occurs in Guatopo National Park (Venezuela) and Asa Wright Nature Centre (Trinidad). Appears to have declined in some areas due to degradation or destruction of forest, with extensive loss of its main food plants, e.g. in Henri Pittier National Park in NW Venezuela.

6. Bronzy Hermit

Glaucis aenea

French: Ermite bronzé **German:** Kupferschattenkolibri **Spanish:** Ermitaño Bronceado
Other common names: Bronze/Chestnut-colored Hermit

Taxonomy. *Glaucis aeneus* Lawrence, 1867, Costa Rica.

Sister species of *G. hirsuta*, and these two often considered conspecific, but they meet in W Panama and W Colombia without interbreeding; present species probably had continuous distribution in past, but now interrupted by *G. hirsuta*, by which it is presumably being gradually replaced. Slight size and weight differences exist between the two discrete populations. Central American birds having longer wings than South American ones, but plumage coloration identical; South American populations sometimes separated as *race cubiana*. Monotypic.

Distribution. E Honduras, E Nicaragua and Costa Rica to W Panama; W Colombia to W Ecuador.

Descriptive notes. 9-10 cm; male 3-6 g, female 3-6 g. Very similar to, but smaller than *G. hirsuta*, with, in general, slightly more decurved bill in both sexes, and upperparts of a regular bronzy or coppery-green colour. Male has throat and upper breast like belly; serrated edges found only on adult male upper mandible. Female has slightly shorter wings than male and more decurved bill with no serration. Immature similar in coloration to that of *G. hirsuta*.

Habitat. Disturbed primary forest, dense or old second growth, forest borders, thickets and shrubbery, swamp forest, near streams. Recorded to 750 m in Costa Rica and 800 m in Colombia.

Food and Feeding. Nectar, e.g. of *Heliconia* species; also small arthropods.

Breeding. May-Aug in Colombia, Jan-Aug in Costa Rica, nest records in Jun, Jul in W Panama, gonadal data also indicate Mar and Apr in Colombia. Nest similar to that of *G. hirsuta*. 2 eggs; development of young similar to *G. hirsuta*.

Movements. Presumably sedentary.

Status and Conservation. Not globally threatened. CITES II. Very common along the Pacific coast of the Chocó region. In the lower Anchicayá Valley, near Buenaventura, SW Colombia, density of at least 2-4 pairs/km² recorded. Recently recorded for first time in Honduras, in catchment area of Río Plátano, where was found to be one of commonest hummingbird species in *Heliconia* thickets. In Pacific lowlands of Costa Rica, present in Corcovado National Park, Carara Biological Reserve and Golfo National Wildlife Refuge. In Ecuador, occurs in Río Palenque Science Centre (S of Santo Domingo).

Bibliography. Anderson *et al.* (1998), Blake & Loiselle (1991), Hilty & Brown (1986), Hinkelmann & Schuchmann (1997), Olson (1993), Prestel (1985), Remsen, Stiles & Scott (1986), Ridgely & Gwynne (1989), Salaman & Mazariegos (1998b), Skutch (1972), Slud (1964), Stiles (1975, 1979, 1980, 1995a, 1995b), Stiles & Skutch (1989), Stotz *et al.* (1996), Wetmore (1968a), Worth (1939, 1942).

Genus THRENETES Gould, 1852

7. Band-tailed Barbthroat

Threnetes ruckeri

French: Ermite de Rucker **Spanish:** Ermitaño Barbudo Colibandeado
German: Weißbinden-Schattenkolibri

Other common names: Rucker's Hermit, Rucker's/Blue Fan-tailed Barbthroat

Taxonomy. *Trochilus Ruckeri* Bourcier, 1847, Esmeraldas, Ecuador.

Proposed race *darienensis* based on birds from an extensive zone of character introgression in E Panama and N Colombia, involving *ventosus*, nominate and *venezuelensis*. Three subspecies currently recognized.

Subspecies and Distribution.

T. r. ventosus Bangs & Penard, 1924 - E Guatemala and Belize to Panama.

T. r. ruckeri (Bourcier, 1847) - N & W Colombia and W Ecuador.

T. r. venezuelensis Cory, 1913 - NW Venezuela.

Descriptive notes. 10-11 cm; male 5.5-7 g, female 5-7 g. A medium-sized hermit with contrasting underpart coloration, almost straight bill, and dark tail feathers with white tips; prominent white base to outer tail feathers, creating broad subterminal black band. Male has more clearly contrast-

open shrubbery, thickets, plantations, near rivers. Recorded from sea-level to 1200 m.

Food and Feeding. Nectar of *Heliconia*, *Costus* and other tubular flowers; also small arthropods, especially spiders. Feeds by trap-lining. Nectar robbery recorded by regular piercing of *Calathea*, some *Heliconia* species, and other tubular blossoms too long for its bill.

Breeding. Feb-May in Costa Rica, Caribbean slope; Jun-Sept in Costa Rica, Pacific slope; nesting recorded May in Honduras, and Dec in Costa Rica; data on gonadal condition indicate Jun in Panama, Jul in Honduras, Jan-Apr and Sept in Colombia. Nest is a more or less loosely built cup of rootlets, plant fibres, vegetable hairs and cobweb, denser than that of *Glaucis*, fixed at the underside tip of a long, pendent leaf. 2 eggs; incubation 15-18 days, by female; fledging 23-25 days; young remain with female for 3-4 weeks. Male observed in the vicinity of an incubating female.

Movements. Presumably sedentary, although some post-breeding movement recorded, in particular of young birds.

Status and Conservation. Not globally threatened. CITES II. Common along forest borders of Pacific slopes of Colombia and NW Ecuador. In foothills of Tumbaco (SW Colombia) density of at least 3-6 pairs/km² recorded; at Río Santiago (NW Ecuador) at least 2-3 pairs/km². In Pacific lowlands of Costa Rica, present in Corcovado National Park, Carara Biological Reserve and Golfito National Wildlife Refuge; in Ecuador, at Tinalandia and Río Palenque Science Centre.

Bibliography. Barlow *et al.* (1972), Blake (1989), Gill (1987), Harms & Ahumada (1992), Hilty (1997), Hilty & Brown (1986), Hinkelmann & Schuchmann (1997), Howell & Webb (1995a), Howell *et al.* (1992), Land & Kiff (1965), Meyer de Schauensee & Phelps (1978), Monroe (1968), Pople *et al.* (1997), Remsen, Stiles & Scott (1986), Ridgely & Gwynne (1989), Robbins & Ridgely (1990), Skutch (1964a, 1972), Slud (1964), Stiles (1979, 1980, 1985b, 1995b), Stiles & Skutch (1989), Stotz *et al.* (1996), Wetmore (1968a), Wood & Leberman (1987).

8. Pale-tailed Barbthroat

Threnetes niger

French: Ermite à queue blanche

German: Orangekehl-Schattenkolibri

Spanish: Ermitaño Barbudo Común

Other common names: White-tailed Barbthroat (*leucurus*); Bronze-tailed Barbthroat (*loehkeni*); Sooty Barbthroat (*niger*); Christina's Barbthroat ("christina")

Taxonomy. *Trochilus niger* Linnaeus, 1758. Cayenne.

Species long known as *T. leucurus*, but taxon *niger*, traditionally considered a separate species, represents a melanistic form of geographically limited distribution, based on apomorphic characters within the range of variation found in *leucurus*; otherwise the two are apparently inseparable, so conspecific treatment seems appropriate, with older name *niger* claiming priority. Since there are several regions from which no or only a few specimens have been secured, exact limits of racial distributions not yet reliably determined. Race *loehkeni* sometimes regarded as separate species; appears to be intermediate between *leucurus* and *niger*; proposed race *freirei* from Amapá (N Brazil) is inseparable from a dull male *loehkeni* and may confirm the intermediate position of latter; both *niger* and *loehkeni* are very rare in scientific collections. In W Amazonia, two zones of character intergradation exist between races *cervinicauda* and *rufigastera* on the one hand, and *leucurus* and *rufigastera* on the other, apparent in belly and tail coloration. Proposed race *cristinae* is synonym of *loehkeni*. Six subspecies currently recognized.

Subspecies and Distribution.

T. n. cervinicauda Gould, 1855 - E Colombia to N Peru and adjacent W Amazonian Brazil.

T. n. rufigastera Cory, 1915 - C Peru to N Bolivia.

T. n. leucurus (Linnaeus, 1766) - S Venezuela, Guyana and Surinam through Amazonian Brazil to N Bolivia.

T. n. niger (Linnaeus, 1758) - French Guiana and adjacent Brazil (N Amapá).

T. n. loehkeni Grantsau, 1969 - NE Brazil N of Amazon (Amapá).

T. n. medianus Hellmayr, 1929 - NE Brazil S of Amazon (Pará).

tips to remiges; in subspecies with light tail feather markings, these are more extensive in adult birds. Racial differences based on colour of belly and the four outer pairs of tail feathers: nominate has uniform dark brownish grey underparts with some lighter shading, where all other races have a bright orange throat; races *cervinicauda* and *medianus* agree in light grey-ochraceous belly coloration, but have light ochraceous (*cervinicauda*) or pastel-coloured (in *medianus* even lighter and brighter ochraceous) tail markings, whereas *loehkeni* differs by uniform dark tail feathers with only some light coloration at tips; *leucurus* has greyish belly and white outer rectrices with some dark only near tips; *rufigastera* has rufous ochraceous belly and white tail feathers as *leucurus*.

Habitat. More open places in humid lowland and higher-altitude tropical forest, river edge forest, transitional and swamp forest, second growth, brushy pastures, plantations. Nominant race often found in riverine habitats, with *Lechnocypus* as characteristic plant. Occurs below 500 m in French Guiana, recorded from sea-level to 1500 m in Peru, to 1600 m in Ecuador.

ing throat, breast and belly, with some iridescent green feathers even on the underparts. Female has shorter wings and tail, and more decurved bill than male. Immature differs by ochraceous feather edges on upperparts and light tips to remiges. Racial differences slight: nominate has smallest extent of pale ochraceous throat coloration, *venezuelensis* more so, but less than *ventosus*, which has extensive bright orange throat and more ochraceous belly than other races; both *ruckeri* and *venezuelensis* have grey bellies.

Habitat. Understorey of primary and disturbed forest, forest edge, dense second growth, semi-

Food and Feeding. Nectar of *Heliconia*, *Costus*, *Monotagma* and other flowering species, as well as small arthropods. Feeds by trap-lining.

Breeding. Nov-Feb, with additional nests recorded May, Sept and Oct in NE Brazil S of Amazon; Jan-Mar in Guyana; data on gonadal activity indicate Jul-Oct in Pará, Brazil; Aug-Nov in Peru; Feb in Ecuador. Nest similar to *Ramphodon naevius* or *Glaucis hirsuta*, but more densely constructed, with more lichens in external wall. 2 eggs; incubation 16-18 days, by female; chick has dusky pinkish skin and dusky down; fledging c. 23-24 days.

Movements. Presumably sedentary.

Status and Conservation. Not globally threatened. CITES II. Local and uncommon throughout distribution range. Regularly seen at the Voltzberg area in Surinam; in French Guiana, present at Saint Georges, Saint Elie and Saul; also occurs in Tambopata Reserve (Peru) and Imataca Forest Reserve (Venezuela). Status and precise distribution of races *niger* and *loehkeni* insufficiently known.

Bibliography. Bond & Meyer de Schauensee (1943), Bloch *et al.* (1991), Cotton (1998a), Davis *et al.* (1991), Dyre (1990), Friedmann (1948), Grantsau (1969, 1988), Gyldenstolpe (1945b), Haverschmidt & Mees (1994), Hilty & Brown (1986), Hinkelmann (1988b), Hinkelmann & Schuchmann (1997), Mayr & Vuilleumier (1983), Meyer de Schauensee & Phelps (1978), Novas (1974), Oniki & Willis (1983), Pacheco (1997), Peres & Whittaker (1991), Remsen & Parker (1983), Remsen, Stiles & Scott (1986), Ruschi (1957a, 1975b, 1976c, 1981-1982, 1986), Sick (1993, 1997), Skutch (1972), Sneath (1935), Snow (1973b, 1981), Stotz *et al.* (1996), Terborgh *et al.* (1984), Tostain *et al.* (1992), Viellard (1994), Vuilleumier & Mayr (1987), Williams & Tobias (1994), Zimmer (1950a).

Genus ANOPETIA Simon, 1918

9. Broad-tipped Hermit

Anopetia gounellei

French: Ermite de Gounelle German: Caatingaschattenkolibri Spanish: Ermitaño Coliancho

Taxonomy. *Phaethornis* [sic] *gounellei* Boucard, 1891, San Antonio da Barra, Bahia, Brazil.

Often placed in genus *Phaethornis*, but different bill and tail morphology support treatment in a separate genus. Monotypic.

Distribution. E Brazil (Piauí to Bahia).

Descriptive notes. c. 11 cm; about 3 g in both sexes. A small hermit hummingbird with bronzy-green upperparts, light brownish to ochraceous underparts, and dark brown throat edged orange-ochraceous. Upper mandible base broadened on both edges thus covering base of lower mandible. Differs from *Phaethornis* in that central pair of rectrices is of similar length as second, or next pair, with larger white tips. Male has broader central rectrices than female, but no obvious differences in tail length and bill curvature; female perhaps has shorter wing than male. Immature birds undescribed.

Habitat. Caatinga region where inhabits more humid areas with shrubs or trees and dense undergrowth; arboreal, shrubby and secondary caatinga. Semi-deciduous forest in the adjacent campo cerrado (S Bahia). Recorded between 500 and 700 m.

Food and Feeding. Nectar and small arthropods. Presumably trap-lining feeding behaviour.

Breeding. Incubation said to be 14 days, fledging up to 20 days. No further information.

Movements. No information available, but presumably sedentary.

Status and Conservation. Not globally threatened. CITES II. Poorly known and might perhaps be classed as Data-deficient. Presumably uncommon in general, although regularly seen; occurs in a relatively unthreatened habitat. In Bahia, regularly recorded in caatinga W of Boa Nova, and also around Canudos. Very rare in scientific collections.

Bibliography. Forrester (1993), Gounelle (1909), Grantsau (1988), Hinkelmann & Schuchmann (1997), Meyer de Schauensee (1982), Olmos (1993), Ruschi (1986), Sargeant (1996), Sick (1993, 1997), Sneath (1928a), Stotz *et al.* (1996), Tobias *et al.* (1993), Willis (1992).

Genus PHAETHORNIS Swainson, 1827

10. White-whiskered Hermit

Phaethornis yaruqui

French: Ermite yaruqui German: Smaragdschattenkolibri Spanish: Ermitaño de Yaruqui

Other common names: Black-winged/Yaruquian Hermit

Taxonomy. *Trochilus Yaruqui* Bourcier, 1851, Yaruqui, Ecuador.

W Colombian populations formerly separated as race *sanctijohannis*, but description was based on immature birds. Monotypic.

Distribution. W Colombia and W Ecuador; possibly SW Panama.

Descriptive notes. c. 13 cm; male 4-7 g, female 4-6.5 g. Medium-sized hermit hummingbird with bluish green upperparts, green to dark grey underparts, and white gular stripe which may be reduced almost to invisibility in older birds. Adult bird has more iridescence in plumage than all other *Phaethornis*. Male has almost straight bill and triangular central rectrices. Female has shorter and slightly decurved bill, shorter wings, more greyish underparts, and longer tail with prominent narrow central rectrices. Immature as female, with ochraceous edges to uppertail-coverts.

Habitat. Humid pre-montane and montane forests, humid secondary growth, dense shrubbery and plantations. Occurs below 2000 m, mostly below 1200 m.

Food and Feeding. Nectar and small arthropods. Flowers visited include *Heliconia*, Ericaceae, Rubiaceae and Bromeliaceae. Feeds by trap-lining.

Breeding. Season undescribed, but data on gonadal activity point to Nov-Jul. Cone-shaped nest, fastened to the underside of long, hanging leaves. 2 eggs. No further information.

Movements. Reports of seasonal movements to higher altitudes in Ecuador, but primarily sedentary. Recent record from SW Panama in Jul possibly refers to an as yet unknown breeding population.

Status and Conservation. Not globally threatened. CITES II. Generally common in wet forests; long-term survival clearly depends on habitat conservation. Commonest *Phaethornis* hermit in Pacific lowlands of Colombia, where

it replaces *P. guy* of higher elevations. Occurs in the 2000-ha Río Nambi Reserve, Nariño (S Colombia). In Ecuador, regularly recorded at El Placer, Tinalandia and Piñas.

Bibliography. Best *et al.* (1997), Borrero (1986), Butler (1979), Engelman (1997), Fjeldså & Krabbe (1990), Hilty (1975, 1997), Hilty & Brown (1986), Hinkelmann & Schuchmann (1997), Oberholser (1902), Remsen, Stiles & Scott (1986), Robbins & Ridgely (1990), Ruschi (1961d, 1981-1982), Rutgers & Norris (1972), Salaman & Mazariegos (1998b), Seutin (1998), Stotz *et al.* (1996), Vuilleumier (1978), Williams & Tobias (1994).

11. Green Hermit

Phaethornis guy

French: Ermite vert **German:** Grüner Schattenkolibri **Spanish:** Ermitaño Verde
Other common names: Guy's/White-tailed Hermit

Taxonomy. *Trochilus Guy* Lesson, 1832, Trinidad.

Race *emiliae* has often been merged into *apicalis*. Species name frequently emended to "guyi", but this is unjustified. Four subspecies currently recognized.

Subspecies and Distribution.

P. g. coruscus Bangs, 1902 - Costa Rica to NW Colombia.

P. g. emiliae (Bourcier & Mulsant, 1846) - Colombia (major river valleys).

P. g. apicalis (Tschudi, 1844) - E Andean slopes from N Colombia and NW Venezuela to SE Peru.

P. g. guy (Lesson, 1832) - Trinidad and NE Venezuela.

Descriptive notes. c. 13 cm; male 4-7 g, female 4-6.5 g. A medium-sized hermit hummingbird very similar to *P. yaruqui*, but with bill distinctly more curved and an always orange gular stripe. Male has nib-shaped central rectrices. Female has shorter and more decurved bill, shorter wings, lighter underparts, ochraceous belly coloration, and a longer tail due to prominent though narrow central rectrices. Immature like female but has ochraceous uppertail-coverts. Nominate is largest race, with greener upperparts and less intensely coloured underparts; races *apicalis* and *emiliae* smaller, with more intensely coloured upperparts and underparts; *apicalis* has a distinctly shorter bill than *emiliae*; W Andean *coruscus* is the brightest, most brilliant race with most extensive distribution of iridescent feathers on underparts.

Habitat. Understorey of mainly humid forest and adjacent forest edges, small clearings, secondary growth, shrubbery and plantations with dense vegetation. Recorded between 600 and 2200 m in Central America and Andean South America, but from sea-level to 1000 m in Trinidad.

Food and Feeding. Nectar of *Heliconia*, *Costus*, *Razisea*, *Columnnea*, *Pachystachys*, *Centropogon* and similar species, even of introduced plants like *Musa* and *Canna*; small arthropods. In N Andes, casual feeding in *Polylepis* woods. Feeds by trap-lining.

Breeding. Nov-Jul, in particular Jan-Apr in Trinidad; Feb-Sept, Dec in Costa Rica and Panama; data on gonadal activity indicate Jun-Aug in Colombia, and Jul-Nov in Peru. Nest construction and site similar to *P. yaruqui*; often situated near rivers and streams. Males reported to defend nest. 2 eggs; incubation 17-18 days, by female with head towards the leaf; fledging period 21-23, rarely to 27 days. Chick has dark skin and sparse down on the back, tightly closed eyes and a rudimentary bill; well feathered when about 2 weeks old.

Movements. Records away from regular range reported from Panama and N Andes, but seasonality of these probably post-breeding movements remains unclear.

Status and Conservation. Not globally threatened. CITES II. Uncommon to fairly common in most areas. In Panama, common in Darién foothills and in highlands above 600 m. Occurs in many protected areas throughout range, e.g. Monteverde Reserve and Tapantí National Park (Costa Rica), Podocarpus National Park (Ecuador), Manu National Park (Peru), Paria Peninsula National Park (Venezuela), and Asa Wright Nature Centre (Trinidad).

Bibliography. Blake, E.R. (1956), Blake, J.G. (1989), Bloch *et al.* (1991), Chapman (1926), Davis (1986), Feinsinger, Tiebout, Young & Murray (1991), Iffrench (1991), Fjeldså & Krabbe (1990), Goussard (1984), Harger (1980), Hayes & Samad (1998), Hilty & Brown (1986), Hinkelmann & Schuchmann (1997), Junge & Mees (1961), Linhart *et al.* (1987), Meyer de Schauensee & Phelps (1978), Parker *et al.* (1982), Rahbek *et al.* (1993), Remsen, Stiles & Scott (1986), Ridgely & Gwynne (1989), Robbins *et al.* (1985), Salaman & Mazariegos (1998a), Schlichmann (1995a), Skutch (1964a), Slud (1964), Snow, B.K. (1973b, 1974, 1977a, 1977b), Snow, B.K. & Snow (1972), Snow, D.W. & Snow (1964, 1980), Stiles (1979, 1980, 1981, 1985b), Stiles & Skutch (1989), Stotz *et al.* (1996), Weske & Terborgh (1977), Wetmore (1968a), Williams & Tobias (1994), Worth (1942), Zimmer (1930, 1950a).

12. White-bearded Hermit

Phaethornis hispidus

French: Ermite d'Osery **German:** Weißbart-Schattenkolibri **Spanish:** Ermitaño Barbiblanco
Other common names: D'Osery's Hermit

Taxonomy. *Trochilus hispidus* Gould, 1846, Bolivia.

Wide distribution and limited knowledge of the species' notable individual variation resulted in the description of two synonyms from E. Ecuador, *oseryi* and *villosus*. Monotypic.

Distribution. Lowlands E. of Andes in Venezuela, Colombia, Ecuador, Peru, Bolivia and W Brazil.

Descriptive notes. c. 13 cm; 4-6 g. A medium-sized hermit hummingbird with bronze upperparts and grey underparts, grey margins to uppertail-coverts, and distinct gular and malar stripes of white coloration; both of these stripes show remarkable variation. Female has slightly shorter and more decurved bill and shorter wings than male. Immature differs by ochraceous margins to uppertail-coverts.

Habitat. Within the humid lowland forest region occurs mainly in regularly inundated habitats: by rivers, in *várzea* and transitional forests, less regularly in secondary growth, *Heliconia* and bamboo thickets, swamp forest

and plantations. Outside humid lowland forest region found in more humid areas such as gallery forests of *campo cerrado*, llanos and semi-deciduous forests. Occurs primarily in lowlands; in Peruvian Andes recorded up to 1200 m.

Food and Feeding. Nectar and small arthropods. Feeds by trap-lining.

Breeding. Season only locally known; breeding record Jun in Colombia; indications of active gonads Jun, Aug, Dec-Apr in Colombia; Dec in Ecuador, Jun to Dec in Peru, and Jul-Sept in Bolivia. Cone-shaped nest, fastened on underside of long, pendent leaf. 2 eggs; fledging period 20-22 days. Further aspects of breeding biology undescribed.

Movements. No information available.

Status and Conservation. Not globally threatened. CITES II. Wide distribution and adaptability probably mean that species is not threatened. Occurs in several protected areas throughout range, e.g. Manu National Park and Tambopata Reserve (Peru).

Bibliography. Bates *et al.* (1989), Best *et al.* (1997), Bond & Meyer de Schauensee (1943), Cotton (1998a), Dyrce (1990), Grantsau (1988), Gyldenstolpe (1945b), Hilty & Brown (1986), Hinkelmann & Schuchmann (1997), Meyer de Schauensee & Phelps (1978), Pearson *et al.* (1977), Remsen & Parker (1983), Remsen, Stiles & Scott (1986), Robinson (1997), Rosenberg, G.H. (1990), Ruschi (1973d, 1981-1982, 1986), Sick (1993), Stotz *et al.* (1996), Terborgh *et al.* (1984), Zimmer (1950a).

13. Western Long-tailed Hermit

Phaethornis longirostris

French: Ermite à longue queue **Spanish:** Ermitaño Colilargo Norteño
German: Westlicher Langschwanz-Schattenkolibri

Other common names: Long-billed Hermit; Jalisco Hermit (*griseoventer*); Mexican/Hartert's Hermit (*mexicanus*); Long-tailed Hermit (*longirostris*)

Taxonomy. *Ornismya longirostris* DeLattre, 1843, Guatemala.

Often considered conspecific with *P. superciliosus*, but with disjunct distributions the two are probably better treated as forming a superspecies. Some forms currently listed as races are well differentiated, and future studies may result in specific separation of *griseoventer*, *mexicanus* and *baroni*; indeed, *mexicanus* (incorporating *griseoventer*) has been recognized by some. Proposed races *veraecrucis* of S Mexico and *cassinii* from Panama and NW Colombia are inseparable from *longirostris* and *cephalus* respectively. Six subspecies currently recognized.

Subspecies and Distribution.

P. l. griseoventer Phillips, 1962 - W Mexico (Nayarit to Colima).

P. l. mexicanus Hartert, 1897 - SW Mexico (W Guerrero to SE Oaxaca).

P. l. longirostris (DeLattre, 1843) - S Mexico (N Oaxaca) to N Honduras.

P. l. cephalus (Bourcier & Mulsant, 1848) - E Honduras to NW Colombia.

P. l. sussurus Bangs, 1901 - N Colombia (Santa Marta Mts).

P. l. baroni Hartert, 1897 - W Ecuador and NW Peru.

Descriptive notes. 13-16 cm; male 5-7.5 g, female 4-6.5 g. A medium-sized hermit hummingbird with greenish-brown back and brownish or greyish underparts. Distinguishable from *P. superciliosus* and other similar species by three (instead of two) light ochraceous bands, with 2 dark bands between them, on the longest feathers of uppertail-coverts; long, decurved bill and long white tips to central rectrices. Female has shorter wings, shorter bill and an even stronger bill decurvature. Race *griseoventer* has white margins to rectrices and pale ochraceous undertail-coverts; *mexicanus* larger and darker below than

nominate; *cephalus* intergrades with *longirostris* from Guatemala to Costa Rica, with more ochraceous underparts, undertail-coverts and tail feather margins from NW to SE; N Colombian *sussurus* larger than *cephalus*, but of same coloration, whereas *baroni* has distinct greyish underparts, white margins to rectrices and whitish undertail-coverts.

Habitat. Rainforest understorey, tall secondary growth, more humid areas in semi-deciduous, pine-oak and cloudforests (in particular in S Mexico and S Ecuador), forest edge, gallery forest and plantations. Recorded from sea-level to 1000 m in Costa Rica, to 2500 m in SW Mexico and N Colombia.

Food and Feeding. Nectar and small arthropods. Resource plants include several species of *Heliconia*, *Costus*, *Aphelandra* and *Passiflora*. Feeds by trap-lining.

Breeding. May-Jul, perhaps earlier and also later in E and SE Mexico; Apr-May in S Mexico, Jan-Sept, perhaps Nov in Costa Rica; May-Sept in Panama; Jan-Apr in N Colombia; data on gonadal condition indicate May in Santa Marta Mts of N Colombia, and Jul in W Ecuador. Nest is thick-walled, cone-shaped cup of plant fibres and cobweb, fastened on the underside of a long, hanging leaf. 2 eggs; incubation 17 to 18 days, by female facing leaf; fledging 22 to 23 days. Nestling has dark skin, sparse down, tightly closed eyes, and short bill.

Movements. No information on any large-scale movements. Presumably wanders short distances.

Status and Conservation. Not globally threatened. CITES II. Small ranges of races *griseoventer*, *mexicanus* and *sussurus* indicate they are potentially at risk; significance increased by possible species status of first two. Race *cephalus* appears to be well protected in extensive network of national parks in Costa Rica, e.g. Manuel Antonio, Corcovado and Cahuita.

Bibliography. Austin (1929), Bangs & Barbour (1922), Berg (1994), Binfod (1989), Blake (1989), Blake & Loiseille (1991), Brodkorb (1943), Dearborn (1907), Des Granges (1979), Des Granges & Grant (1980), Fraga (1989), Friedmann *et al.* (1950), Gill (1987), Gill *et al.* (1982), Griseom (1932b), Hafler (1975), Hernández-Baños *et al.* (1995), Hilty & Brown (1986), Hinkelmann (1996b), Hinkelmann & Schuchmann (1997), Howell, S.N.G. &

14. Eastern Long-tailed Hermit

Phaethornis superciliosus

French: Ermite à brins blancs **Spanish:** Ermitaño Colilargo Común
German: Östlicher Langschwanz-Schattenkolibri
Other common names: Cayenne/Guiana/Allied/Buff-browed Hermit; Rusty-breasted Hermit (*superciliosus*)

Taxonomy. *Trochilus superciliosus* Linnaeus, 1766, Cayenne. Often considered conspecific with *P. longirostris*, but with disjunct distributions the two are probably better treated as forming a superspecies; all races of *P. malaris* except nominate have also traditionally been attributed to present species instead, but their affinities appear to lie with that species. Race *muelleri* has been associated with *P. malaris ochraceiventris*. Venezuelan birds sometimes separated as race *saturator*, but they fall within variation found in nominate race. A single hybrid of nominate *superciliosus* with *P. m. malaris* was found at a locality of sympatric occurrence. Two subspecies recognized.

Subspecies and Distribution.
P. s. superciliosus (Linnaeus, 1766) - S Venezuela, the Guianas and N Brazil (N of Amazon in Pará and Roraima).
P. s. muelleri Hellmayr, 1911 - N Brazil (S of Amazon in Pará and Maranhão).

Descriptive notes. c. 14 cm; 4-6 g. A medium-sized brownish hermit hummingbird very similar to *P. longirostris* and *P. malaris*, but distinguished from the former by two light ochraceous bands on the longest feathers of the uppertail-coverts, and from the latter, even in adult males, by a distinct gular stripe. Female has shorter wings, and a shorter, less decurved bill. Immature with light

ochraceous feather margins on the upperparts. Race *muelleri* has darker throat and breast, and in both sexes less decurved bill than nominate.

Habitat. Understorey of lowland rainforest and adjacent semi-deciduous forest, forest edge, gallery forest, second growth, riverine habitats such as river edge, *igapó* and *várzea* forest. Recorded from sea-level to 1400 m in S Venezuelan mountains.

Food and Feeding. Nectar of plants such as *Heliconia* and *Passiflora*, and small arthropods. Feeds by trap-lining.

Breeding. Breeding records in Jan, Jun, Sept and Nov in N Brazil, S of Amazon; Sept in N

Brazil, N of Amazon; Mar, Jun-Aug in Guyana; Aug-Oct in French Guiana; gonadal data indicate Nov in Brazil N of Amazon, as well as Jul and Aug in N Brazil S of Amazon. Nest similar to that of *P. longirostris*. 2 eggs; incubation at least 16 days, by female with head facing leaf, bill pointing upwards and backwards, and tail cocked up; fledging c. 21-22 days; chick has dark pinkish skin and light brown down.

Movements. No information available.

Status and Conservation. Not globally threatened. CITES II. Common throughout its range. Abundant in the Voltzberg Nature Reserve in Surinam, with recorded density of at least 3-4 pairs/km². Species is still found in bird exports from Surinam and French Guiana to EU countries, although numbers of birds exported have no detectable impact on populations.

Bibliography. Berlioz (1964), Bertin & Wilzbach (1979), Bierregaard & Lovejoy (1989), Borges (1985), Capparella (1987), Cotton (1998a), Davis (1934, 1958), Diek *et al.* (1984), Friedmann (1948), Grantsau (1988), Griscom & Greenway (1941), Haverschmidt & Mees (1994), Hinkelmann (1996a, 1996b), Hinkelmann & Schuchmann (1997), Lovejoy (1974), Meyer de Schauensee & Phelps (1978), Nicholson (1931), Novaes (1969, 1970, 1980), Oniki & Willis (1982, 1983), Prestel (1983), Ruschi (1981-1982, 1986), Rutgers & Norris (1972), Sick (1993, 1997), Skutch (1964a), Snethlage (1913, 1935), Snow (1973b), Stötz *et al.* (1996), Stauffer & Bierregaard (1995, 1996), Teixeira, Nacinovic & Luigi (1989), Teixeira, Nacinovic & Pontual (1987), Todd (1942), Tostain *et al.* (1992), Willard *et al.* (1991), Willis (1977), Young (1971), Zimmer (1950a).

15. Great-billed Hermit

Phaethornis malaris

French: Ermite à long bec **German:** Dunkler Schattenkolibri **Spanish:** Ermitaño Picogrande
Other common names: Margaretta's Hermit (*margarettae*)

Taxonomy. *Trochilus malaris* Nordmann, 1835, Cayenne.

Often considered monotypic, but most races hitherto regarded as belonging to *P. superciliosus* apparently have closer affinities with present species. Race *ochraceiventris* may prove to merit treatment as a separate species, but this would probably not include all S Amazonian taxa of this species-group (including *P. superciliosus muelleri*), as has been suggested. Race *margarettae* has been considered a full species. Races *moorei* and *bolivianus* intergrade in E Andes of Peru, and offspring of these described as "ucayaliti". Birds occurring between lower reaches of R Madeira and R Tapajós were separated as *insignis*, but indistinguishable from *bolivianus*. Proposed race *camargoi* inseparable from *margarettae*. Six subspecies currently recognized.

Subspecies and Distribution.

P. m. insolitus Zimmer, 1950 - E Colombia, S Venezuela, adjacent N Brazil.
P. m. malaris (Nordmann, 1835) - Surinam and French Guiana to CN Brazil (Amapá).
P. m. margarettae Ruschi, 1972 - coastal E Brazil (Pernambuco to Espírito Santo).
P. m. moorei Lawrence, 1858 - E Colombia, E Ecuador and N Peru.
P. m. ochraceiventris Hellmayr, 1907 - NE Peru and W Brazil to lower R Madeira (S of Amazon).
P. m. bolivianus Gould, 1861 - SE Peru, Bolivia and W Brazil to W bank of R Tapajós (S of Amazon).

Descriptive notes. 13-17 cm; male 4.5-10 g, female 4-8 g. Medium-sized to large hermit similar to *P. superciliosus*, but with gular stripe faint or absent in adult male; like *P. longirostris*, but with only two pale ochraceous bands on longest uppertail-coverts. Female has shorter wings and bill, latter slightly more decurved. Immature has pale ochraceous feather margins on upperparts. Nominant race is largest, with darkest underparts; *insolitus* very similar to *malaris* but smaller, intergrades with *moorei*, which has paler, greyer underparts. Race *bolivianus* smaller than *moorei*, with dark brown throat and breast and orange-ochraceous belly; very similar, perhaps with

paler underparts and different tail coloration, is geographically distant *margarettae*. Race *ochraceiventris* larger than last three, with breast and belly bright orange.

Habitat. Understorey of unindented lowland rainforest of the *terra firme*, pre-montane and humid upper tropical forest, transitional forest, second growth, bamboo thickets, shrubbery; race *ochraceiventris* found in *igapó* forest. Usually below 600 m, but up to 1500 m in Colombian and 1650 m in Bolivian Andes, though recorded up to 2400 m.

Food and Feeding. Nectar of *Heliconia*, *Pitcairnia*, etc. and small arthropods. Feeds by trap-lining.

Breeding. Occupied nests Aug-Dec, French Guiana; gonadal activity Jun-Sept in Bolivia, Jun-Nov in Peru. Nest as in *P. longirostris*. 2 eggs; incubation 14-15+ days, by female; fledging probably 20-23 days.

Movements. No information available.

Status and Conservation. Not globally threatened. CITES II. Race *margarettae*, limited to forest remnants in E Brazil, could be threatened by further habitat destruction.

Bibliography. Blake (1962), Capparella (1987), Dick *et al.* (1984), Fjeldså & Krabbe (1989), Goussard (1984), Grantsau (1988), Haverschmidt & Mees (1994), Hinkelmann (1988b, 1989b, 1996a, 1996b), Hinkelmann & Schuchmann (1997), King (1978/79), McKay (1980), Mees (1977b), Novaes (1974, 1976), Parker *et al.* (1982), Peres & Whittaker (1991), Phelps & Phelps (1958), Pinto (1978), Prestel (1983), Remsen, Stiles & Scott (1986), Robbins *et al.* (1991), Ruschi (1972, 1973d, 1976a, 1981-1982, 1982a, 1986), Schulenberg *et al.* (1984), Seilern (1934), Sick (1993, 1997), Snow (1981), Stotz *et al.* (1996), Teixeira, Naciniovic & Luigi (1989), Teixeira, Naciniovic & Pontual (1987), Terborgh & Weske (1975), Terborgh *et al.* (1984), Todd (1942), Tostain *et al.* (1992), Zimmer (1950a).

16. Tawny-bellied Hermit

Phaethornis syrmatorphorus

French: Ermite à ventre fauve **Spanish:** Ermitaño Ventrihabano
German: Orangebauch-Schattenkolibri
Other common names: Trainbearing/Baron Rothschild Hermit

Taxonomy. *Phaethornis syrmatorphorus* Gould, 1851, western Ecuador.

Closest to *P. koepckeae* and *P. philippii*. Races well distinguished and might be different species. Description of *berlepschi* based on an immature bird of nominate race; *huallagae*, described for birds from N Peru, is inseparable from *columbianus*. Two subspecies currently recognized.

Subspecies and Distribution.

P. s. syrmatorphorus Gould, 1851 - W Andes of Colombia (including Cauca/Patía Valley) to SW Ecuador.
P. s. columbianus Boucard, 1891 - E Andes of Colombia, including S Magdalena Valley, to N Peru.

Descriptive notes. c. 14 cm; 5-7 g. A medium-sized hermit hummingbird with a prominent long, distinctly decurved bill, olive-green upperparts and reddish-orange uppertail-coverts; belly, undertail-coverts and tail feather margins bright orange. Female has slightly more decurved bill and shorter wings. Immature has light ochraceous margins to feathers of upperparts, giving a scaly appearance. Race *columbianus* differs in having a dark brown (instead of orange) throat and breast, and often has some white feathers on breast and belly.

Habitat. Understorey of humid montane forest, sometimes at forest edge or in dense second growth. Generally between 1000 and 2300 m, although records exist between 750 and 3100 m.

Food and Feeding. Nectar and small arthropods. Feeds by trap-lining.

Breeding. Recorded Jun in Ecuador; gonadal activity Dec in Peru; birds in breeding condition Mar-Aug and Dec in Colombia. Elongated, cone-shaped nest made of dry leaves, vegetable fibres, and fern scales, surrounded by silk and attached to underside tip of pendulous leaf. 2 eggs. No further data.

Movements. No information available. Presumably resident.

Status and Conservation. Not globally threatened. CITES II. Habitat loss may be a severe threat in the future. Regularly recorded in Cueva de los Guácharos National Park, and La Planada and Rio Nambi Reserves, Colombia; also at Mindo, Coca Falls, between Baeza and Tena, and near Piñas, Ecuador.

Bibliography. Best & Clarke (1991), Best, Clarke *et al.* (1993), Best, Heijnen & Williams (1997), Bloch *et al.* (1991), Butler (1979), Davies *et al.* (1994), Fjeldså & Krabbe (1990), González (1998), Graves (1985), Hilty (1997), Hilty & Brown (1986), Hinkelmann & Schuchmann (1997), Marin & Carrión (1994), Miller (1963), Parker *et al.* (1982), Rahbek *et al.* (1993), Remsen, Stiles & Scott (1986), Ridgely & Gaulin (1980), Robbins & Ridgely (1990), Salaman & Mazariagos (1998b), Stotz *et al.* (1996), Zimmer (1950a).

17. Koepcke's Hermit

Phaethornis koepckeae

French: Ermite de Koepcke **Spanish:** Ermitaño de Koepcke
German: Orangebrauner Schattenkolibri

Taxonomy. *Phaethornis koepckeae* Weske and Terborgh, 1977, Cerros del Sira, Peru.

In past, sometimes placed in genus *Ametornis*. Closely related to *P. philippii*, replacing it at higher elevations; also related to *P. syrmatorphorus*. Significant differences in size between some populations may be the result of long-term isolation. Monotypic.

Distribution. Slopes of isolated mountains along E Andes in Peru.

Descriptive notes. c. 13 cm; male 4-6 g, female 4-5.5 g. Medium-sized hermit with straight bill, olive-green upperparts, orange-red uppertail-coverts, and bright orange underparts. Similar to *P. syrmatorphorus columbianus*, but without white feathers on breast and belly. In contrast to *P. philippii*, has dark brown throat with whitish malar and gular stripes. Female has shorter bill and wings; very slight decurvature in female bill visible. Immature has ochraceous feather margins on the upperparts.

Habitat. Moist upper tropical forest understorey, rarely in second growth. Recorded between 270 and 1130 m.

Food and Feeding. Nectar and small arthropods. Feeds by trap-lining.

Breeding. Gonadal activity Aug-Oct. Small conical nest similar to that of other *Phaethornis*, attached to the underside of a long pendulous leaf near its tip. 2 eggs; nest with 2 young found Jul.

Movements. No information available. Presumably resident.

Status and Conservation. Not globally threatened. CITES II. Currently considered Near-threatened. Has been found so far at no more than 10 localities. Regularly recorded at Amazonia Lodge, near Manu National Park (Peru), at an old tea plantation situated between subtropical and tropical forests, at altitude of 457 m.

Bibliography. Davis (1986), Hinkelmann (1987, 1988b), Hinkelmann & Schuchmann (1997), Meyer de Schauensee (1982), Parker *et al.* (1982), Remsen, Stiles & Scott (1986), Stotz *et al.* (1996), Vuilleumier & Mayr (1987), Weske & Terborgh (1977).

18. Needle-billed Hermit

Phaethornis philippii

French: Ermite de Filippi **Spanish:** Ermitaño Picoaguja
German: Orangefarbener Schattenkolibri

Taxonomy. *Trochilus Philippii* Bourcier, 1847, Bolivia.

In past, sometimes placed in genus *Ametornis*. Closely related to *P. koepckeae*, replacing it at lower elevations; also related to *P. syrmatorphorus*. Monotypic.

Distribution. E Peru, N Bolivia and W Brazil (S of Amazon to W bank of R Tapajós).

Descriptive notes. c. 12 cm; male 4-6 g, female 4-5.5 g. A straight-billed hermit hummingbird, smaller than *P. koepckeae*, but very similar in coloration, with entire throat, breast and belly orange. Female has shorter wings and bill, but with almost no visible curvature. Immature has ochraceous feather margins on upperparts.

Habitat. Understorey of lowland rainforest, sometimes at forest edge; occurs in *terra firme*, *várzea*, bamboo thickets and plantations. Recorded up to 325 m.

Food and Feeding. Nectar and small arthropods. Feeds by trap-lining.

Breeding. Gonadal activity Jun and Jul in Peru and N Bolivia. No further information available.

Movements. No information available.

Status and Conservation. Not globally threatened. CITES II. Locally common in understorey of lowland forest especially in E Peru (e.g. Tambopata Reserve). Status of population in W Brazil is not known.

Bibliography. Allen (1995), Donahue (1994), Dyrce (1990), Forrester (1993), Grantsau (1988), Hilty & Brown (1986), Hinkelmann (1988b), Hinkelmann & Schuchmann (1997), Novaes (1957, 1976), Parker & Remsen (1987), Parker *et al.* (1982), Peres & Whittaker (1991), Remsen & Traylor (1989), Remsen, Stiles & Scott (1986), Robbins *et al.* (1991), Ruschi (1981-1982, 1986), Sick (1993), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Traylor (1958a), Zimmer (1950a).

On following pages: 19. Straight-billed Hermit (*Phaethornis bourcierii*); 20. Pale-bellied Hermit (*Phaethornis anthophilus*); 21. Scale-throated Hermit (*Phaethornis eurynome*); 22. Planalto Hermit (*Phaethornis pretrei*); 23. Sooty-capped Hermit (*Phaethornis augusti*); 24. Buff-bellied Hermit (*Phaethornis subochraceus*); 25. Dusky-throated Hermit (*Phaethornis squalidus*); 26. Streak-throated Hermit (*Phaethornis rupurumii*); 27. Little Hermit (*Phaethornis longuemareus*); 28. Minute Hermit (*Phaethornis idaliae*); 29. Cinnamon-throated Hermit (*Phaethornis nattereri*); 30. Reddish Hermit (*Phaethornis ruber*); 31. White-browed Hermit (*Phaethornis stuarti*); 32. Black-throated Hermit (*Phaethornis atrimentalis*); 33. Stripe-throated Hermit (*Phaethornis striigularis*); 34. Grey-chinned Hermit (*Phaethornis griseogularis*).

19. Straight-billed Hermit

Phaethornis bourcieri

French: Ermite de Bourcier

German: Braunbauch-Schattenkolibri

Spanish: Ermitaño Piquirrecto

Taxonomy. *Trochilus Bourcieri* Lesson, 1832, Cayenne.

In past, sometimes placed in genus *Ametromis*. Morphological characters argue against close relationship to other hermits with straight bills, *P. philippii* and *P. koepckeae*. Many authors have accepted additional race *whitelyi* for northern birds, but claimed characters correspond to individual variation, both types of coloration occurring throughout range of nominate race. Two subspecies recognized.

Subspecies and Distribution.

P. b. bourcieri (Lesson, 1832) - E Colombia and N Peru to S Venezuela, Guianas and Brazil N of Amazon.
P. b. major Hinkelmann, 1989 - Brazil S of Amazon along E bank of lower R Tapajós.

Descriptive notes. 12-13 cm; 4-5 g. Medium-sized hermit with olive-green upperparts and brownish ("whitelyi coloration") to greyish ("bourcieri coloration") underparts; straight bill. Female has shorter wings and bill; almost no curvature visible in bill. Immature has light ochraceous edging to feathers of upperparts. Race *major* significantly larger in all measurements, with plumage coloration similar to nominate form with greyish underparts.

Habitat. Understorey of lowland *terra firme* rainforest, and dense areas of adjacent semi-deciduous or pre-montane forest, up to 1600 m in S Venezuelan mountains; occasionally at forest edge, in bamboo thickets, dense shrubbery, *várzea* forest, second growth or plantations.

Food and Feeding. Nectar and small arthropods. Recorded at flowers of *Manettia*, *Guzmania* and *Vriesea*; feeds by trap-lining.

Breeding. Mar-May in Brazil; active nests Sept in Manaus and Amapá, Brazil, Oct in French Guiana, Sept in Colombia; gonadal activity Sept in Colombia, and Jul, Aug, Oct, Nov in Peru. Nest is long, cone-shaped cup of plant matter and cobweb fastened under tip of long, hanging leaf. 2 eggs; incubation 17-18 days, by female; fledging c. 23 days. At hatching, chick has eyes closed and down scattered over body.

Movements. No information available.

Status and Conservation. Not globally threatened. CITES II. Common throughout its range. Regularly seen in primary forest at the Voltzberg Nature Reserve, Surinam, with local population density of at least 2-3 pairs/km². Occurs in several protected areas, e.g. Amacayacu National Park (Colombia) and Imataca Forest Reserve (Venezuela).

Bibliography. Bierregaard & Lovejoy (1989), Cotton (1998a), Dickerman & Phelps (1982), Friedmann (1948), Grantsau (1988), Haverschmidt & Mees (1994), Hilty & Brown (1986), Hinkelmann (1989a), Hinkelmann & Schuchmann (1997), Meyer de Schauensee & Phelps (1978), Oniki & Willis (1982), Parker *et al.* (1982), Remsen, Stiles & Scott (1986), Rosenberg, G.H. (1990), Ruschi (1981-1982, 1986), Snow (1981), Stotz *et al.* (1996), Stouffer & Bierregaard (1995, 1996), Tostain *et al.* (1992), Weske & Terborgh (1977), Willard *et al.* (1991), Willis (1977), Zimmer (1950a).

20. Pale-bellied Hermit

Phaethornis anthophilus

French: Ermite anthophile

German: Fleckenkehl-Schattenkolibri

Spanish: Ermitaño Ventripálido

Other common names: Black-cheeked Hermit

Taxonomy. *Trochilus anthophilus* Bourcier, 1843, upper Magdalena Valley, Colombia.

In past, sometimes placed in genus *Ametromis*. An almost straight-billed hermit without close relatives, somewhat resembling *P. euryome*. A melanistic bird of doubtful origin was described as race *fuliginosus*, but never verified as referring to a valid population. Birds of nominate race in E Andes of Colombia have smaller wings and bill than other populations and may be separable as *fuscescapillus*, which these differences also be confirmed in Venezuelan birds. Two subspecies recognized.

Subspecies and Distribution.

P. a. hyalinus Bangs, 1901 - Pearl Is (off Pacific coast of Panama).

P. a. anthophilus (Bourcier, 1843) - C Panama to Colombia (Magdalena Valley and E of Andes) and N Venezuela.

Descriptive notes. c. 13 cm; male 4.5-5.5 g, female 4-5 g. A medium-sized hermit hummingbird with dark green to olive-green upperparts and light grey underparts, distinguishable from all other *Phaethornis* of similar size by lack of a gular stripe, which is replaced by light feather fringes giving a scaly or striped appearance. Male has almost straight bill. Female has shorter wings and bill clearly decurved. Immature has light ochraceous feather margins on the upperparts. Racial differences slight; *hyalinus* has lighter coloration of underparts and more bluish green than dark green upperparts.

Habitat. Semi-deciduous forest and several types of drier woodland, second growth, brushy edges, thorny thickets, plantations and gallery forest. Recorded from sea-level to about 1500 m.

Food and Feeding. Nectar of *Heliconia*, *Brownea*, etc., and small arthropods. Feeds by trap-lining.

Breeding. Nest construction recorded Dec in Colombia; breeding Oct-Feb and Apr in Venezuela; gonadal condition indicates Apr and Jun in Venezuela, and Oct-Mar in Colombia. Cone-shaped cup nest attached under tip of a pendent leaf as typical for the genus. 2 eggs. No further details.

Movements. Records Apr and Dec in NE Venezuela may indicate regular movements; more data needed.

Status and Conservation. Not globally threatened. CITES II. Uncommon to locally common. Abundant in drier areas of coastal Venezuela and at head of Magdalena Valley, Colombia. Population near Santa Marta shows density of at least 1-2 pairs/km². Occurs in Tayrona and Henri Pittier National Parks, in NE Colombia and NC Venezuela respectively.

Bibliography. Durlington (1931), Friedmann & Smith (1950, 1955), Hilty & Brown (1986), Hinkelmann & Schuchmann (1997), Mack & Fisher (1990), Meyer de Schauensee & Phelps (1978), Miller (1952), Ridgely & Gwynne (1989), Schäfer & Phelps (1954), Schuchmann (1984a), Stiles (1995c), Stotz *et al.* (1996), Todd & Carriger (1922), Wetmore (1939, 1946, 1968a).

21. Scale-throated Hermit

Phaethornis euryome

French: Ermite euryome

German: Schuppenkehl-Schattenkolibri

Spanish: Ermitaño Escamoso

Other common names: Black-billed Hermit ("nigrirostris")

Taxonomy. *Trochilus euryome* Lesson, 1832, Brazil.

Similar to *P. anthophilus*, both species apparently lacking close relatives. Includes "*P. nigrirostris*", based on a unique specimen of nominate race with uniformly black bill. Two subspecies recognized.

Subspecies and Distribution.

P. e. paraguayensis M. Bertoni & W. Bertoni, 1901 - E Paraguay and NE Argentina (Misiones).

P. e. euryome (Lesson, 1832) - SE Brazil (Bahia to Rio Grande do Sul).

Descriptive notes. c. 14 cm; male 4.5-6 g, female 4-5 g. Medium-sized hermit, olive above and greyish below, having dark throat feathers with narrow light-coloured edges, giving a scaly appearance; with broad white tail feather margins and yellowish lower mandible. Female has shorter wings and slightly more decurved bill. Race *paraguayensis* is identical in coloration but significantly smaller.

Habitat. Understorey of lowland and montane rainforest, humid areas in semi-deciduous forest, especially in SW of range, and old second growth. In N of range, common in mountainous regions. Recorded at 100-2250 m.

Food and Feeding. Nectar taken from *Heliconia*, *Centropogon*, *Costus*, *Neoregelia*, *Nidularium*, *Reichsteineria*, *Sinningia*, *Siphocampylus*, *Impatiens*, *Besleria*, *Passiflora*, *Quesnelia*, *Tillandsia*, *Vriesea*, *Aechmea*, *Canistrum*, *Alstroemeria*, *Salvia*, *Dahlstedtia*, *Nematanthus*, *Jacobinia*, *Manettia* and other plant species, and small arthropods. Feeds by trap-lining.

Breeding. Sept-Mar in Brazil. Long cone-shaped cup of plant material and cobweb attached to inner tip of leaf of a palm, fern, *Heliconia*, etc. Nests are often decorated with *Spiloma*, a lichen releasing red pigment when in contact with the breeding female. As a consequence, both the bird's underparts and eggs take on a pink coloration. 2 eggs; incubation about 17 days, by female; fledging 22-23 days.

Movements. No information available. Presumably sedentary.

Status and Conservation. Not globally threatened. CITES II. Common throughout its range. In forest patches in the Tibagi Basin, Paraná, Brazil, population density recorded as at least 1-2 pairs/km². Frequently recorded in Iguazú Falls National Park, in both Brazil and Argentina. Occurs in Serra dos Orgãos and Itatiaia National Parks.

Bibliography. Belton (1984), Brooks *et al.* (1993), Canevari *et al.* (1991), Fischer (1994), Gonzaga *et al.* (1995), Grantsau (1988), Hayes (1995), Hinkelmann (1988b), Hinkelmann & Schuchmann (1997), Höfling & Lencioni (1992), King (1978/79), Lowen, Bartrina, Clay & Tobias (1996), Lowen, Clay *et al.* (1995), Mayr & Vuilleumier (1983), Oniki (1996), de la Peña (1994), do Rosário (1996), Ruschi (1973a, 1981-1982, 1982a, 1986), Saibene *et al.* (1996), Sazima *et al.* (1995), Scott & Brooke (1985), Sick (1979, 1993, 1997), Snow & Snow (1986), Snow & Teixeira (1982), Storer (1989), Stotz *et al.* (1996), Willis (1992), Willis & Oniki (1981).

22. Planalto Hermit

Phaethornis pretrei

French: Ermite de Prêtre

German: Zimtroter Schattenkolibri

Spanish: Ermitaño del Planalto

Taxonomy. *Trochilus Pretrei* Lesson and DeLattre, 1839, Minas Gerais, Brazil.

Forms superspecies with *P. augusti*. Proposed races "*garleppi*" and "*pallidiventris*" based on aberrant specimens; *schwarti* (Bahia) and *minor* (N Goiás, S Maranhão) based on individual variation. Monotypic.

Distribution. Bolivia, N Argentina and Paraguay to Brazil S of Amazonian rainforest area.

Descriptive notes. c. 14 cm; male 4.5-5.5 g, female 4-5 g. Medium-sized hermit with olive-green upperparts, prominent reddish upperpart-coverts, cinnamon-red underparts, and a distinctly elongated second (next to central) pair of rectrices with prominent white tips. Female has shorter wings and shorter, less decurved bill. Immature has pale feather fringes on upperparts.

Habitat. Non-forest, vegetation-rich areas, or dry forest, predominantly in mountainous regions, also second growth, forest edge and gallery forest. Also well adapted to human environments if rich in trees and herbs. Found between 400 and 2100 m.

Food and Feeding. Nectar of various flowering plants; small arthropods. Probably feeds by trap-lining.

Breeding. Sept-Apr in Brazil; nest records in Sept in NW Argentina and Aug in Brazil. Nest is a long, cone-shaped cup constructed of plant matter and spider web, but, in contrast to other *Phaethornis*, fixed on vertical structure like roots and twigs, or protected in cavity on rock face or similar situation; other sites include on wires in man-made hollows like culverts, waste-water pipes, under bridges and even in abandoned buildings. Sometimes a suitable site will be used again, and a new nest is constructed on the old one. 2 eggs; incubation about 15 days, by female; fledging at least 20 days. Chick has a roseate skin coloration. Male observed in the nest vicinity in the breeding period.

Movements. No reliable information available; thought to be partly migratory within certain areas.

Status and Conservation. Not globally threatened. CITES II. Common throughout range. Accepts man-made habitats, e.g. gardens, parks. In SE Brazil, abundance varies from 2 pairs/km² in natural habitats to at least 5 pairs/km² in larger city parks. Occurs in several protected areas, e.g. Callegua National Park (Argentina) and Serra dos Orgãos, Serra da Canastra and Serra do Cipó National Parks (Brazil).

Bibliography. Bond & Meyer de Schauensee (1943), Camperi (1990), Canevari *et al.* (1991), Castellano & Moreyra (1986), Cintra & Yamashita (1990), Contreras (1986), Contreras *et al.* (1990), Esteban (1947), Fjeldså & Krabbe (1990), Fjeldså & Mayer (1996), Forrester (1993), Fraga *et al.* (1984), Grantsau (1988), Hayes (1995), Hinkelmann & Schuchmann (1997), Marini *et al.* (1997), Mitchell (1957), Nores & Yzurieta (1981), Oniki (1996), Pacheco (1997), de la Peña (1994), Remsen & Traylor (1989), Remsen, Stiles & Scott (1986), do Rosário (1996), Ruschi (1950c, 1951, 1975a, 1973d, 1976d, 1981-1982, 1982a, 1986), Saibene *et al.* (1996), Schmitt *et al.* (1997), Short (1975), Sick (1993, 1997), Sick & Teixeira (1981), da Silva & Oniki (1988), Stager (1961), Storer (1989), Stotz *et al.* (1996), Tobias *et al.* (1993), Todd (1942), Willis (1979).

23. Sooty-capped Hermit

Phaethornis augusti

French: Ermite d'Auguste **German:** Graubauch-Schattenkolibri **Spanish:** Ermitaño Limpicaca

Taxonomy. *Trochilus augusti* Bourcier, 1847, Caracas, Venezuela.

Forms superspecies with *P. pretrei*. Includes "*P. fumosus*", based on melanistic specimen of nominate. Colombian birds described as race *vicarius* do not differ from nominate. Three subspecies recognized.

Subspecies and Distribution.

P. a. curiosus Wetmore, 1956 - Santa Marta Mts (N Colombia).

P. a. augusti (Bourcier, 1847) - E Andes and Macarena Mts (Colombia), and coastal Cordillera (Venezuela).

P. a. incanescens (Simon, 1921) - isolated mountains of S Venezuela and W Guyana.

Descriptive notes. c. 14-15 cm; male 4-5-6 g, female 4-5 g. Medium-sized hermit, very similar to *P. pretrei*, but with uniform grey underparts. Differs from *P. hispidus* by rufous uppertail-coverts and prominent white tips to elongated second rectrices (next to central pair). Female has shorter wings and more decurved bill, but these differences less evident than in similar species. Immature has pale feather margins on upperparts. Racial differences slight: *curiosus* has palest underparts and broadest, though indistinct, white gular stripe of all populations; *incanescens* differs by having narrower and less intensely coloured uppertail-coverts.

Habitat. Understorey of semi-deciduous and fairly dry to humid montane forest, dense vegetation in mainly mountainous non-forest habitats, forest edge, second growth and plantations. Recorded to 1800 m in S Venezuelan highlands and to 3500 m in N Venezuelan Andes; rarely below 500 m.

Food and Feeding. Nectar, taken by by trap-lining; small arthropods, sometimes sought in buildings.

Breeding. Active nests found Feb-Jul and Sept-Dec in N Venezuela. Nest-site and construction similar to *P. pretrei*, and with a peculiar counterweight constructed of pieces of dried mud attached to the nest wall by spider web to create stability. Clutch size 2. Breeding biology is probably very like that of *P. pretrei*, but there is no additional information.

Movements. Probably mostly sedentary, but some seasonal vertical movement and straggling noted.

Status and Conservation. Not globally threatened. CITES II. Common to locally uncommon. Easy to see in coastal Cordillera of Venezuela and in Santa Marta Mts of Colombia, with density of at least 1-2 pairs/km². Appears to adapt well to habitats modified by man, so probably quite secure. Occurs in Guatopo, Cueva del Guácharo and Henri Pittier National Parks (Venezuela).

Bibliography. Chubb (1916), Fjeldså & Krabbe (1990), Forrester (1993), Friedmann & Smith (1955), Gilliard (1941, 1959), Grantsau (1988), Hilty & Brown (1986), Hinkelmann & Schuchmann (1997), Mayr & Phelps (1967, 1971), Meyer de Schauensee & Phelps (1978), Ruschi (1981-1982, 1986), Schäfer & Phelps (1954), Sick (1993), Snyder (1966), Stotz *et al.* (1996), Thomas (1993), Wetmore (1939).

24. Buff-bellied Hermit

Phaethornis subochraceus

French: Ermite ocré **German:** Ockerbauch-Schattenkolibri **Spanish:** Ermitaño Ocráceo

Taxonomy. *Phaethornis subochraceus* Todd, 1915, Santa Cruz de la Sierra, Bolivia.

Like *P. squalidus* and other small hermits, but more closely related to *P. pretrei* and *P. augusti*. Monotypic.

Distribution. E Andean lowlands of Bolivia and adjacent Brazil (Mato Grosso).

Descriptive notes. 11-12 cm; 3-5-4 g. A small, dull brownish hermit hummingbird with ochraceous (buff) belly, best told by distinctly elongated second pair of rectrices and prominent white margins on all rectrices. Female has shorter wings than male. Immature has pale feather margins on upperparts.

Habitat. Undergrowth in hilly, deciduous and dry semi-deciduous forest, second growth, open woodland and shrubs. Recorded at 150-800 m.

Food and Feeding. Nectar and small arthropods. No additional information available.

Breeding. Birds in breeding condition in Jun, Jul and Oct, Bolivia. No reliable description of nest.

Incubation said to be by female and to last 14-15 days, fledging 20 days; but data require confirmation.

Movements. No information available. Presumably sedentary.

Status and Conservation. Not globally threatened. CITES II. Locally common. Poorly known, and should perhaps be classed as Data-deficient. Regularly recorded in dry deciduous forest near Samaipata (EC Bolivia) and in Pantanal of Mato Grosso (WC Brazil). Very rare in scientific collections.

Bibliography. Bond & Meyer de Schauensee (1943), Cintra & Yamashita (1990), Davis (1993), Dubs (1992), Forrester (1993), Grantsau (1988), Hinkelmann & Schuchmann (1997), Meyer de Schauensee (1982), Remsen & Traylor (1989), Remsen, Schmitt & Schmitt (1990), Remsen, Stiles & Scott (1986), Ruschi (1981-1982, 1986), Sick (1993, 1997), Short (1975), Stotz *et al.* (1996), Willis & Oniki (1990).

25. Dusky-throated Hermit

Phaethornis squalidus

French: Ermite terne **German:** Dunkelkehl-Schattenkolibri **Spanish:** Ermitaño Escualido
Other common names: Sooty-throated Hermit

Taxonomy. *Trochilus squalidus* Temminck, 1822, Ipanema, São Paulo, Brazil.

One of the small hermits sometimes separated in genus *Pygornis*; present species has the most primitive characters of any member of this group, linking these species with the larger members of genus *Phaethornis*. Often considered to include *P. rupurumii*, but morphological characters indicate that that species is more closely related to *P. longuemareus* and *P. idaliae*. Proposed race "*maranhaoensis*", sometimes considered a full species, has proved to be the hitherto undescribed adult male plumage of *P. nattereri*. Monotypic.

Distribution. SE Brazil (S Minas Gerais and Espírito Santo to Santa Catarina).

Descriptive notes. 10-11 cm; 2-5-3-5 g. A small, dull brownish hermit, intermediate in size, though sometimes as small as some individuals of the small species; brownish ochraceous underparts and a dark brown throat. Sexes alike in coloration, measurements and bill curvature.

Habitat. Understorey of humid littoral and adjacent montane forest, and dense secondary growth. Recorded from sea-level to 2250 m.

Food and Feeding. Nectar and small arthropods. No detailed studies.

Breeding. Oct-Feb. Nest is cone-shaped cup attached to the inner tip of a long, pendent leaf. 2 eggs; incubation given as 14 days, by female.

and fledging said to be 20-22 days; data require confirmation.

Movements. No information available. Presumably sedentary.

Status and Conservation. Not globally threatened. CITES II. Recorded as frequent in Tijuca National Park near Rio de Janeiro. Continuing destruction of rainforest may present a major threat in future.

Bibliography. Aleixo & Galetti (1997), dos Anjos *et al.* (1997), Forrester (1993), Grantsau (1988), Hinkelmann & Schuchmann (1997), Meyer de Schauensee (1982), Oniki (1996), Parker & Goerck (1997), Pinto (1954), do Rosário (1996), Ruschi (1981-1982, 1982a, 1986), Scott & Brooke (1985), Sick (1993), Stotz *et al.* (1996), Tobias *et al.* (1993), Willis (1992).

26. Streak-throated Hermit

Phaethornis rupurumii

French: Ermite balafré **German:** Strichelkehl-Schattenkolibri **Spanish:** Ermitaño del Rupununi

Taxonomy. *Phaethornis* [sic] *Rupurumii* Boucard, 1892, Rupununi River, Guyana.

One of the small hermits sometimes separated in genus *Pygornis*. Often considered conspecific with *P. squalidus*, but morphological characters indicate it is more closely related to *P. longuemareus* and *P. idaliae*. Future studies may reveal that geographically isolated race *amazonicus* should be considered a full species. A hybrid of present species with *P. longuemareus* was described as "*P. longuemareus imatacae*"; another with *P. ruber ruber* as "*P. longuemareus aethopyga*". Two subspecies recognized.

Subspecies and Distribution.

P. r. rupurumii Boucard, 1892 - extreme E Colombia (E Vichada) through C & E Venezuela and W Guyana to adjacent N Brazil.

P. r. amazonicus Hellmayr, 1906 - along lower R Amazon in NC Brazil.

Descriptive notes. 10-11 cm; 2-5-3 g. Like *P. squalidus* in size and coloration, but differs in having white (nominate) or sometimes light buffy (*amazonicus*) instead of ochraceous undertail-coverts, and a brownish grey (nominate) instead of ochraceous belly. Adult male has more intensely dark brown throat feathers, presenting a streaky appearance. Female has broader light margins to rectrices than male. Immature resembles adult female.

Habitat. Understorey of rainforest edge, várzea forest and various drier habitats drier, e.g. semi-deciduous forest, gallery forest and forest islands in non-forest regions, thickets, second

growth, scrub, etc.; along both banks of lower Amazon in "*campos* islands" with corresponding vegetation adapted to drier conditions. Mainly lowlands, but up to 500 m in Venezuela and Guyana.

Food and Feeding. Nectar and small arthropods, but no detailed information.

Breeding. No information available.

Movements. No information available.

Status and Conservation. Not globally threatened. CITES II. At least locally common. Very poorly known, and should perhaps be classed as Data-deficient. Frequently recorded (*rupurumii*) near Puerto Ayacucho, Venezuela, and (*amazonicus*) near Manaus, Brazil.

Bibliography. Cherrie (1916), Chubb (1916), Forrester (1993), Grantsau (1988), Hilty & Brown (1986), Hinkelmann (1996a), Hinkelmann & Schuchmann (1997), Meyer de Schauensee & Phelps (1978), Moskovits *et al.* (1985), Pinto (1947), Ruschi (1981-1982, 1986), Sergeant (1994a), Sick (1993, 1997), Sneath (1913), Snyder (1966), Stotz *et al.* (1996), Zimmer & Hilty (1997).

27. Little Hermit

Phaethornis longuemareus

French: Ermite nain **German:** Brauner Zwergschattenkolibri **Spanish:** Ermitaño Chico
Other common names: Longuemare's/Rusty-breasted Hermit

Taxonomy. *Trochilus Longuemareus* Lesson, 1832, Cayenne.

One of the small hermits sometimes separated in genus *Pygornis*. Usually considered to include *P. idaliae*, *P. atrimentalis* and *P. strigularis*; morphological characters, however, indicate that they should be treated as separate species, with latter two not even very closely related to present species; *P. idaliae* is closest relative. Invalid races proposed include: "*imatacae*" based on hybrid of present species with *P. rupurumii*; and "*aethopyga*" based on hybrid of *P. rupurumii* with *P. ruber ruber*. Monotypic.

Distribution. Trinidad and NE Venezuela to French Guiana.

Descriptive notes. 9 cm; male 3-3-8 g, female 2-5-3-8 g. A small hermit hummingbird with olive-green upperparts, orange-ochraceous belly, white undertail-coverts, and clearly pointed central rectrices. Smaller than *P. squalidus* and *P. rupurumii*. Male has intensely dark brown throat. Female has less extensive dark throat coloration and broader buff margins to rectrices than male. Immature resembles adult female.

Habitat. Typically occurs in understorey of various more open forest habitats like swamp and mangrove forest, dense second growth, thickets, scrub, forest edge, or plantations on

South American mainland. In Trinidad, however, preferred habitat is rainforest. Recorded from sea-level to 700 m.

Food and Feeding. Nectar of *Heliconia*, *Pachystachys*, *Costus*, *Palicourea*, *Mandevilla*, *Justicia*, *Cephaelis* and many other flowering plants, and small arthropods. Feeds by trap-lining.

Breeding. Dec-Jun, but most nests Jan-Mar in Trinidad. Active nests were found in Jan and Aug in Surinam; Jan, Jul and Aug in French Guiana. Nest is a long cone-shaped cup of plant material and cobweb, attached to the underside tip of a pendent leaf. 2 eggs. No further data.

Movements. No information available. Presumably sedentary.

Status and Conservation. Not globally threatened. CITES II. Common to locally common. In the Arima Valley of Trinidad, population densities of at least 3-5 pairs/km²; at the Voltzberg Nature Reserve in Surinam, at least 1 pair/km². Occurs in Asa Wright Nature Centre (Trinidad).

Bibliography. Arp (1957), Bangs & Penard (1918), Chubb (1916), Dobkin (1987), Feinsinger (1983), Iffrench (1991), Haverschmidt & Mees (1994), Hayes & Samad (1998), Herklots (1961), Hinkelmann (1988c, 1990a, 1990b, 1996a), Hinkelmann & Schuchmann (1997), Junge & Mees (1961), Meyer de Schauensee & Phelps (1978), Phelps & Phelps (1952, 1958), Ruschi (1981-1982, 1986), Rutgers & Norris (1972), Snow, B.K. & Snow (1972), Snow, D.W. (1968), Snow, D.W. & Snow (1964), Snyder (1966), Stotz *et al.* (1996), Tostain *et al.* (1992), Wiley (1971).

28. Minute Hermit

Phaethornis idaliae

French: Ermite d'Italie **German:** Schiller-Zwergschattenkolibri **Spanish:** Ermitaño Pigmeo

Taxonomy. *Trichilus idaliae* Bourcier and Mulsant, 1856, Rio de Janeiro, Brazil.

One of the small hermits sometimes separated in genus *Pygmornis*. Often considered a race of *P. longuemareus*, its closest relative, but sexual dimorphism and other morphological characters indicate that they should be treated as separate species. Monotypic.

Distribution. SE Brazil (Bahia to Rio de Janeiro).

Descriptive notes. 8 cm; 2-2.5 g. Very small, sexually dimorphic hermit with pointed central rectrices and dark green iridescent upperparts. Male has dark brown throat, with some patchy iridescent feathers on breast. Female has orange-ochraceous throat and breast, and broader tail feather margins than male; underparts remarkably similar in coloration to female *P. longuemareus*, but that species larger. Immature female like adult female; immature male has breast darker than adult female, but paler than adult male; tail feather margins as broad as in female.

Habitat. Understorey of primary or only slightly disturbed littoral forest, forest edge,

old secondary growth, forest islands within the coastal *cerrado* (*restinga*). Occurs below 500 m.

Food and Feeding. Nectar and small arthropods. Feeds by trap-lining.

Breeding. Oct-Feb. Nest similar to *P. longuemareus*; 2 eggs; incubation by female, at least 14 days; fledging 20 days, sometimes more.

Movements. No information available. Presumably sedentary.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species; present in Atlantic Forest Lowlands EBA. Confined to a vulnerable rainforest habitat, further destruction of which may pose a severe threat to the survival of the species; should perhaps be classed as Data-deficient or Near-threatened. Occurs in Rio Doce State Park (Minas Gerais) and Sooretama Biological Reserve (Espírito Santo). Rare in scientific collections.

Bibliography. Forrester (1993), Grantsau (1988), Hinkelmann & Schuchmann (1997), Oniki (1996), Parker & Goerck (1997), Ruschi (1967c, 1981-1982, 1982a, 1986), Scott & Brooke (1985), Sick (1969, 1993, 1997), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Tobias *et al.* (1993), Willis (1992).

29. Cinnamon-throated Hermit

Phaethornis nattereri

French: Ermite de Natterer **German:** Zimtkehl-Schattenkolibri **Spanish:** Ermitaño de Natterer
Other common names: Maranhão Hermit

Taxonomy. *Phaethornis nattereri* Berlepsch, 1887, Caiçara and Engenho da Gama, Mato Grosso. One of the small hermits sometimes separated in genus *Pygmornis*. Similar to *P. subochraceus* and *P. squalidus*, but morphological characters indicate a closer relationship to *P. ruber*, *P. stuarti*, *P. atrimentalis*, *P. strigularis* and *P. griseogularis*. Recently described "*P. maranhensis*", which was considered a full species or a race of *P. squalidus*, has proved to be the hitherto undescribed adult male plumage of present species. The two populations appear to be geographically isolated. Monotypic.

Distribution. E Bolivia and adjacent SW Brazil (Mato Grosso); also NE Brazil (Maranhão to Ceará).

Descriptive notes. 10 cm; 2.5-3 g. Small hermit, smaller and paler brown than *P. squalidus* and *P. subochraceus*, but larger than most congeners; has ochraceous undertail-coverts. Throat coloration in adult male more intense than in female, but not as dark as in the dark-throated species *P. longuemareus*, *P. rapurumii*, *P. idaliae* and *P. atrimentalis*. Central rectrices of adult male pointed and thus similar to those species, not rounded as in the remainder. With these, *P. ruber*, *P. stuarti*, *P. atrimentalis*, *P. strigularis* and *P. griseogularis*, shares elongated reddish unbanded uppertail-coverts. Female same size as adult male, differing by lighter throat and

longer central rectrices. Immature resembles adult female.

Habitat. Inhabits variety of vegetation-rich habitats outside rainforest; semi-deciduous forest, second growth, thickets, *cerrado*, arboreal *caatinga*, forest islands and gallery forest. Occurs below 500 m.

Food and Feeding. Nectar of *Pavonia*, *Helicteres*, *Ruellia*, *Bauhinia* and other flowering plants, as well as small arthropods. Feeds by trap-lining.

Breeding. No information available.

Movements. No information available. Presumably sedentary.

Status and Conservation. Not globally threatened. CITES II. Poorly known, and should perhaps be classed as Data-deficient. Perhaps locally common. In Brazil, occurs in Chapada dos Guimarães

National Park (Mato Grosso) and in dry woodlands of Araguaia National Park (Goiás). Sometimes also reported as occurring along lower R Amazon in Pará, although validity of reports doubtful. Rare in scientific collections.

Bibliography. Bates *et al.* (1989), Dubs (1992), Forrester (1993), Grantsau (1968a, 1988), Hinkelmann (1988a, 1988b, 1990b), Hinkelmann & Schuchmann (1997), Mayr & Vuilleumier (1983), Olmos (1993), Pinto (1978), Remsen & Traylor (1989), Ruschi (1953a, 1967a, 1981-1982, 1986), Sargeant (1996), Sick (1993, 1997), da Silva & Oniki (1988), Stotz *et al.* (1996), Vuilleumier & Mayr (1987), Willis & Oniki (1990).

30. Reddish Hermit

Phaethornis ruber

French: Ermite roussâtre **German:** Roter Zwergschattenkolibri **Spanish:** Ermitaño Rojizo
Other common names: Red-vented/Pygmy Hermit

Taxonomy. *Trichilus ruber* Linnaeus, 1758, Surinam.

One of the small hermits sometimes separated in genus *Pygmornis*. Forms a species group or even superspecies with *P. stuarti*, and the two are often considered conspecific; there is very close geographical contact, if not sympatry, and one natural hybrid recorded. Other close relatives are *P. atrimentalis*, *P. strigularis* and *P. griseogularis*. There is a zone of character introgression between nominate and race *longipennis*, but no such zone has been found between present species and *P. stuarti*. Future investigation may confirm species status for current races *nigricinctus* and *episcopus*, other taxa apparently lacking introgression with nominate *ruber*. Birds of SE Brazil have been separated as race *pygmaeus*, but claimed differences took insufficient account of age- and sex-related individual variation homogeneously distributed over entire range of nominate race. Synonyms for species include *P. rufiventris* and *P. rufigaster*. A hybrid of nominate *ruber* with *P. rapurumii* was described as "*P. longuemareus aethopyga*". Four subspecies recognized.

Subspecies and Distribution.

P. r. episcopus Gould, 1857 - C & E Venezuela, Guyana and adjacent N Brazil.

P. r. ruber (Linnaeus, 1758) - Surinam and French Guiana through Brazil to SE Peru and N Bolivia.

P. r. nigricinctus Lawrence, 1858 - extreme SW Venezuela and E & S Colombia to N Peru.

P. r. longipennis Berlepsch & Stolzmann, 1902 - S Peru.

Descriptive notes. 8-9 cm; 2-3 g. A small hermit hummingbird with dark green upperparts and cinnamon-rufous underparts. Male regularly has some dark feathers forming a patch or even a band on the breast, and a shorter tail with rounded rectrices showing narrow white or reddish tips. Female has paler breast and belly coloration, with longer wings and tail, the rectrices having broader margins than in male. Immature resembles adult female, male with shorter wings. Adult male of *episcopus* also has white margins to rectrices; this race is same size as nominate and coloration of underparts tends more to orange-rufous than cinnamon-rufous of *ruber*;

nigricinctus smallest, with adult male having the most intense rufous underparts and white instead of rufous tail feather margins, while female differs in size from nominate; *longipennis* is largest and closest to *P. stuarti* in having a whitish chin, while prominent tips to central rectrices are rufous and thus same colour as light margins of all tail feathers in this race as well as in nominate.

Habitat. Understorey of lowland, pre-montane and littoral rainforest of the *terra firme*, *várzea* and semi-deciduous forest, forest edge and forest islands in more open habitats, as well as *cerrado*, savanna woodland, thickets and second growth. Mainly in the lowlands, but recorded to 1500 m in S Peru, 1200 m in N Bolivia, and 1100 m in Venezuela.

Food and Feeding. Nectar and small arthropods. Flowering plants visited include *Trichanthera*, *Petreaea*, *Costus*, *Dahlstedtia*, *Nematanthus*, *Psychotria* and many others. In SE Brazil, nectar robbery by piercing the corolla base appears to be a regular feeding strategy. Feeds by trap-lining.

Breeding. May-Oct in NE Brazil, Oct-Feb in SE Brazil; active nests found in Jan, May-Oct in the Guianas. Data on gonadal condition indicate Nov in S Peru; Jun, Aug in N Peru. Nest is cone-shaped cup of diverse plant fibres, leaves, mosses, lichens, seed plumes and cobweb fastened to the inner tip of a long, hanging leaf. 2 eggs; incubation 15-17 days, by female, sitting with her bill directed towards the leaf; fledging period between 15 and 22 days. Chick has roseate skin with two lines of light brown down on the back; eyes open at 6 days old. Female cares for her offspring for a few days after they leave the nest. In the Belém area, cells of *Pison* wasps appear to be a regular occurrence in the lower part of the nest, though there is no obvious advantage for the bird.

Movements. No reliable information available. Presumably sedentary.

Status and Conservation. Not globally threatened. CITES II. Locally common to abundant. Sites at which species is frequently recorded include: Imataca Forest Reserve, Bolívar (Venezuela); several localities around Georgetown (Guyana); near Mana and in Nouragues (French Guiana); Serra dos Órgãos National Park, Rio de Janeiro, and around Porto Seguro and Boa Nova, Bahia (Brazil); and near Satja, between Santa Cruz and Cochabamba (Bolivia). In Voltzberg Nature Reserve, Surinam, recorded density of at least 2-4 pairs/km².

Bibliography. Bates *et al.* (1989), Bond & Meyer de Schauensee (1943), Davis, T.A.W. (1934, 1958), Davis, T.J. (1986), Dubs (1992), Dyrce (1990), Forrester (1993), Friedmann (1948), Goussard (1984), Grantsau (1988), Gyldestolpe (1945b), Haverschmidt (1954b), Haverschmidt & Mees (1994), Hilty & Brown (1986), Hinkelmann (1986, 1996a), Hinkelmann & Schuchmann (1997), Meyer de Schauensee & Phelps (1978), Novaes (1970, 1973, 1980), Oniki (1970), Oniki & Willis (1983), Peres & Whittaker (1991), Pinto (1953), Remsen, Stiles & Scott (1986), Robens & Robens (1984), Ruschi (1949a, 1973d, 1981-1982, 1982a, 1986), Rutgers & Norris (1972), Sazima *et al.* (1995), Schuchmann (1986), Sick (1993, 1997), Sick & Teixeira (1981), Sneath (1982a, 1982b, 1935), Snow (1973b), Stager (1961), Stotz *et al.* (1996), Terborgh & Weske (1969), Terborgh *et al.* (1984), Tostain *et al.* (1992), Willard *et al.* (1991), Willis (1977), Zimmer (1950a).

31. White-browed Hermit

Phaethornis stuarti

French: Ermite de Stuart **German:** Stuarts Zwergschattenkolibri **Spanish:** Ermitaño Boliviano

Taxonomy. *Phaethornis stuarti* Hartert, 1897, Salinas, River Beni, Bolivia.

One of the small hermits sometimes separated in genus *Pygmornis*. Forms a species group or even superspecies with *P. ruber*, of which often considered a race; there is very close geographical contact, if not sympatry, and one natural hybrid recorded but no zone of character introgression. Other close relatives are *P. atrimentalis*, *P. strigularis* and *P. griseogularis*. Monotypic.

Distribution. SE Peru to C Bolivia.

Descriptive notes. c. 9 cm; male 2-2.5 g, female 2-3 g. A small hermit hummingbird very similar to *P. ruber*, in particular to race *longipennis*, from which it is distinguishable by white tail feather margins and prominent white tips to central rectrices. Sexual dimorphism as in *P. ruber*.

Habitat. Understorey of transitional forest (between *várzea* and *terra firme* rainforest), bamboo thickets, second growth, hilly tropical forest, scrub and similar habitats. Recorded to 1000 m.

Food and Feeding. Nectar and small arthropods. No detailed information available.

Breeding. No information available.

Movements. No information available. Presumably sedentary.

Status and Conservation. Not globally threatened. CITES II. Very poorly known, and should probably be classed as Data-deficient; research and survey work required. Regularly seen between Cuzco and Manu, SE Peru.

Bibliography. Bond & Meyer de Schauensee (1943), Brace *et al.* (1997), Hinkelmann (1996a), Hinkelmann & Schuchmann (1997), Meyer de Schauensee (1982), Olrog (1968), Parker *et al.* (1982), Remsen & Parker (1983), Remsen & Taylor (1989), Stotz *et al.* (1996), Terborgh *et al.* (1984), Zimmer (1950a).

32. Black-throated Hermit

Phaethornis atrimentalis

French: Ermite à gorge noire

German: Schwarzkehl-Schattenkolibri

Spanish: Ermitaño Barbinegro

Taxonomy. *Phaethornis atrimentalis* Lawrence, 1858. Napo, Ecuador.

One of the small hermits sometimes separated in genus *Pygornis*. Frequently considered conspecific with *P. longuemareus*, but morphological characters indicate closest relationship is to *P. ruber* and *P. stuarti*. Other close relatives are *P. striigularis* and *P. griseogularis*. Two subspecies recognized.

Subspecies and Distribution.

P. a. atrimentalis Lawrence, 1858 - E Andes of Colombia, Ecuador and N Peru.

P. a. riojae (Berlepsch, 1889) - C Peru.

Descriptive notes. 8-9 cm. Very similar to *P. ruber*, but easily distinguishable by prominent dark brown throat and whitish undertail-coverts. Male has a more intensely coloured throat, shorter wings than female (not regularly in race *riojae*), and, as adult, narrower tail feather margins. The central rectrices are usually rounded, but pointed ones also occur. Dark feathers on the cinnamon-red breast, forming a dark patch or even a band, are regularly found in males. Race *riojae* is significantly larger than nominate.

Habitat. Understorey of lowland rainforest, in particular at edges, second growth areas, zones transitional to more open habitats, plantations, swamp forest. Usually in lowlands but recorded in Andes S of Marañón Valley to 1200 m.

Food and Feeding. Nectar of flowering plants like *Costus*, *Aechmea*, *Palicourea*, *Drymonia*, *Gurania*, *Pitcairnia*, as well as small arthropods.

Breeding. No nest yet described. Data on gonadal activity indicate breeding in Jul and Nov (Peru), and Sept (Ecuador).

Movements. No information available. Presumably sedentary.

Status and Conservation. Not globally threatened. CITES II. Present in Río Nambi Reserve, Nariño, and Amacayacu National Park, S Amazonas (Colombia); also recorded near Tingo María (C Peru).

Bibliography. Hilty & Brown (1986), Hinkelmann (1988c, 1990a, 1990b), Hinkelmann & Schuchmann (1997), McKay (1980), Remsen, Stiles & Scott (1986), Schulenberg *et al.* (1984), Snow (1981), Zimmer (1930, 1950a).

33. Stripe-throated Hermit

Phaethornis striigularis

French: Ermite à gorge rayée

German: Streifenkehl-Schattenkolibri

Spanish: Ermitaño Gorgiestriado

Other common names: Dusky/Boucard's Hermit (*saturatus* = *adolphi*)

Taxonomy. *Phaethornis striigularis* Gould, 1854. Bogotá, Colombia.

One of the small hermits sometimes separated in genus *Pygornis*. Often considered conspecific with *P. longuemareus*, but morphological characters indicate closest relationship is to *P. griseogularis*; race *saturatus* in particular is extremely similar to *P. g. griseogularis*. Other close relatives include *P. atrimentalis*, *P. ruber* and *P. stuarti*. Race *saturatus* (= *adolphi*) sometimes treated as a separate species. Further races proposed in Mexico (*cordobae* = *adolphi*) and Panama (*nelsoni* = *fraterculus*) judged invalid, as claimed differences fail to take into account age- and sex-related variation in *saturatus*. In NW Colombia, races *saturatus*, *subrufescens* and *striigularis* come together in a zone of character introgression. Name *adolphi* pre-dates *saturatus*, but considered to be preoccupied by almost identical name; *adolphi* therefore subsequently replaced by *cordobae*, but this in turn becomes junior synonym of *saturatus*. Four subspecies currently recognized.

Subspecies and Distribution.

P. s. saturatus Ridgway, 1910 - S Mexico (S Veracruz) to NW Colombia.

P. s. subrufescens Chapman, 1917 - W Colombia and W Ecuador.

P. s. striigularis Gould, 1854 - N Colombia (and Magdalena Valley) and adjacent W Venezuela.

P. s. ignobilis Todd, 1913 - N Venezuela.

Descriptive notes. c. 9 cm; male 2-3 g, female 2-3.2 g. A small hermit hummingbird, olive-green above, brownish to greyish below, with darker throat than breast and belly, but without dark breast feathers. Adult male has clearly rounded central rectrices with lighter narrow margins. Female has longer wings, less intensely coloured throat and breast, more pointed central rectrices with broader margins than male. Immature resembles adult female. Races well differentiated: nominate *striigularis* has throat feathers with light margins, creating a streaky appearance; this character also evident in

subrufescens and *ignobilis*, though less distinct; nominate has palest and greyest underparts; *subrufescens* and *ignobilis* have brown-ochraceous throat and breast, more intense and less grey in *subrufescens*; race *saturatus* is brightest, with ochraceous orange underparts and rufous instead of ochraceous tail feather margins.

Habitat. Understorey of humid tropical lowland and hilly forest, in tree-gaps, clearings and forest edge, dense second growth woodland, vegetation-rich plantations and even gardens; races *striigularis* and *ignobilis* additionally in semi-deciduous forest, scrub and thickets. Recorded from sea-level to 1300 m in Venezuela, 1500 m in Costa Rica and 1800 m in W Ecuador.

Food and Feeding. Nectar of a large variety of flowers with medium-sized or small corollae, and small arthropods. Nectar robbery by piercing the corolla bases of *Scutellaria* and *Pavonia* observed in Costa Rica and Panama respectively. Feeds by trap-lining.

Breeding. May-Jul in S Mexico; Apr-Jul, Nov, Dec, with records Sept and Feb (or possibly even all year round) in Costa Rica; active nests recorded Jul in W Colombia, Jan-Mar in W Ecuador, May and Jun in Belize. Data on gonadal condition indicate breeding Mar and May in N Colombia; Mar and Dec in W Colombia, May in Panama, and Apr in Honduras. Nest is compact, cone-shaped cup of plant material including fibres and down, held together by cobweb, attached to the underside tip of a long, hanging leaf. 2 eggs; incubation 15-16 days, by female; fledging period 20-23 days. Chick has pink skin, with a double row of light brownish down on the back; eyes remain closed until 10 days old.

Movements. No information. Seasonal occurrence in N Venezuela may indicate some migration.

Status and Conservation. Not globally threatened. CITES II. Common throughout its range, especially along the Pacific coast of Colombia. In the Anchiwayá Valley, near Buenaventura, SW Colombia, population density at least 1-2 pairs/km². Occurs in Manuel Antonio, Braulio Carrillo and Corcovado National Parks (Costa Rica).

Bibliography. 34. Grey-chinned Hermit

Phaethornis griseogularis

French: Ermite à gorge grise

German: Binden-Zwergschattenkolibri

Spanish: Ermitaño Barbigrís

Other common names: Grey-throated Hermit; Gould's Hermit (*zonura*); Porculla Hermit (*porcullae*)

Taxonomy. *Phaethornis griseogularis* Gould, 1851. Bogotá, Colombia.

One of the small hermits sometimes separated in genus *Pygornis*. Closest to *P. striigularis*. Other close relatives include *P. atrimentalis*, *P. ruber* and *P. stuarti*. Races *zonura* and *porcullae* are rare in scientific collections, and latter may be classed as separate species when more detailed information is available; *zonura* has been treated as synonym of nominate *griseogularis*. Three subspecies currently recognized.

Subspecies and Distribution.

P. g. griseogularis Gould, 1851 - W of Andes in Colombia; E Andes from Colombia to N Peru; S & SE Venezuela and adjacent N Brazil on several isolated mountains.

P. g. zonura Gould, 1860 - NW Peru (Cajamarca and adjacent Amazonas).

P. g. porcullae Carriker, 1935 - W Andean mountains in NW Peru (Tumbes, Piura and Lambayeque).

Descriptive notes. 8-10 cm; male 2-2.5 g, female 2-3 g. Very similar to *P. striigularis*, but always distinguishable by pointed outer primaries, and prominent grey band on upperside of central rectrices between the usually blackish base and the whitish tip; presence and extent of black breast band variable. Sexual dimorphism as *P. striigularis*; male has greyish throat and rounded rectrices with narrow light margins. Female has longer wings, lighter underparts, and longer rectrices with broader margins. Immature resembles adult female. Nominat *griseogularis* significantly smaller than *P. striigularis saturatus*, but has similar coloration on under-

parts. Races *zonura* and *porcullae* larger than nominate, with *porcullae* being largest and similar in size to *P. nattereri* or *P. longuemareus*. Where *zonura* differs by paler, more greyish underparts and a more decurved bill, *porcullae* has even lighter underparts and white margins on the 3 inner pairs of rectrices; these margins are white with some ochraceous in the outermost rectrices.

Habitat. Understorey of humid pre-montane, subtropical and lower montane cloudforest, forest edge, dense second growth, thickets, in E Colombia also in gallery forest; race *zonura* prefers dry tropical woodland, and *porcullae* humid woodland and moist forest remnants in seasonally dry forest. Usually between 600 and 2000 m; in E Colombia recorded below 400 m.

Food and Feeding. Nectar and small arthropods. Feeds by trap-lining.

Breeding. Gonadal data indicate breeding in Oct in Colombia; Jan, May and Jun in NW Peru. Nest hitherto undescribed, breeding biology presumably similar to *P. striigularis*.

Movements. No information available. Presumably sedentary.

Status and Conservation. Not globally threatened. CITES II. Limited distribution of races *zonura* and *porcullae* could be a cause for future concern. Nominat race regularly recorded between Garzón and Florencia (SC Colombia), and along Loreto road between Tena and Coca (E Ecuador).

Bibliography. Barrowclough & Escalante (1990), Barrowclough *et al.* (1995), Best & Clarke (1991), Bloch *et al.* (1991), Butler (1979), Davis (1986), Grantsau (1988), Hilty & Brown (1986), Hinkelmann (1990b), Hinkelmann & Schuchmann (1997), Meyer de Schauensee & Phelps (1978), Phelps & Phelps (1965), Rahbek *et al.* (1993), Remsen, Stiles & Scott (1986), Ruschi (1981-1982, 1986), Salaman & Mazariegos (1998a, 1998b), Schuchmann (1987a), Sick (1993, 1997), Stotz *et al.* (1996), Willard *et al.* (1991), Williams & Tobias (1994), Zimmer (1950a).

PLATE 47

Subfamily TROCHILINAE

Genus *ANDRODON* Gould, 1863

35. Tooth-billed Hummingbird

Andron aequatorialis

French: Colibri d'Équateur **German:** Zahnschnabelkolibri **Spanish:** Colibrí Piquidentado
Other common names: Ecuadorian Toothbill, Equatorial/Cadet Hummingbird

Taxonomy. *Andron aequatorialis* Gould, 1863, Ecuador. Controversial discussion continues as to whether this species belongs in Phaethornithinae or Trochilinae. Based on external morphology, hindneck musculature, and behaviour it has even been placed, together with members of genus *Doryfera*, in a separate subfamily Doryferinae, phylogenetically ranked between the hermits and non-hermits. Behavioural and molecular studies suggest that the species is not related to the Phaethornithinae. Monotypic.

Distribution. E Panama and W Colombia (Chocó) to NW Ecuador.

Descriptive notes. 13.2-14.2 cm (including 4 cm of bill); male 9 g, female 7 g. Male has straight bill with hooked tip, distal half or less with backward-pointing tooth-like serrations, black above, yellow below tipped dark; forehead sooty brown, crown metallic reddish copper, back green, rump reddish copper, tail-coverts dull greenish blue, bordered above by a narrow white band; underparts greyish, sides of head, throat and breast broadly streaked black; tail rounded, greyish green, with dark subterminal band and broad white tips. Female like male, but lacks hook on bill, duller on crown, less heavily streaked below. Immature

has crown and nape greenish blue, coppery band on rump small or lacking.

Habitat. Occurs from sea-level to 1100 m, mainly in understorey of primary forest. Forages from middle to lower strata; occasionally found at forest edge and in secondary growth along ravines.

Food and Feeding. Forages for nectar at flowering shrubs and epiphytes such as Ericaceae and Gesneriaceae. The tooth-like serrations are perfectly suited to collecting main prey, spiders, from leaves, embankment cavities, or narrow holes; occasionally male probes with hooked bill in curled dead leaves in search of arthropod prey. Feeds mainly by trap-lining.

Breeding. Reproductive biology virtually unknown. Indirect evidence for breeding season is indicated by enlarged gonads of individuals in SW Colombia Jan-Mar; in NW Ecuador males gather at leks during Feb-May in forest understorey.

Movements. Sedentary.

Status and Conservation. Not globally threatened. CITES II. Common resident of undisturbed primary forest, with densities of at least 3-5 individuals/km². Seems to have disappeared in parts of SW Colombia (N & W Buenaventura) due to extensive logging; present in Río Nambi Reserve (Pasto area).

Bibliography. Anon. (1998a), Best *et al.* (1997), Butler (1979), Gill & Gerwin (1989), Hilty (1997), Hilty & Brown (1986), Meyer de Schauensee (1982), Ridgely & Gwynne (1989), Robbins *et al.* (1985), Salaman (1996), Salaman & Mazariegos (1998b), Schuchmann (1992, 1995b), Selander (1966), Stotz *et al.* (1996), Wetmore (1968a).

Genus *DORYFERA* Gould, 1847

36. Green-fronted Lancebill

Doryfera ludovicae

French: Porte-lance de Louise **Spanish:** Colibrí Picolanza Mayor
German: Grünstirn-Lanzettschnabel

Taxonomy. *Trochilus ludovicae* Bourcier and Mulsant, 1847, Buena Vista, east Andes above Villavicencio, Meta, Colombia.

Genus formerly placed in subfamily Phaethornithinae, due largely to confusion regarding its nest; now known to be part of the basal radiation of the Trochilinae; in many older works generic name *Hemistephania* was used. Two proposed races, *rectirostris* (W Andes of Colombia and NW Ecuador) and *grisea* (NW Bolivia), now usually subsumed into nominate race; former differs only in bill averaging longer, but with wide overlap, and latter based on characters of an immature male, birds of this age being indistinguishable from those of nominate. Species name sometimes misspelt *ludoviciae*. Two subspecies currently recognized.

Subspecies and Distribution.

D. l. veraguensis Salvin, 1867 - NC Costa Rica to W Panama.

D. l. ludovicae (Bourcier & Mulsant, 1847) - extreme E Panama (Cerro Tacarcuna), Colombia and W Venezuela S through Andes to NW Bolivia (E slope only from C Ecuador southwards).

Descriptive notes. 11-13 cm; male 5.9 g and female 5.5 g in *veraguensis*, male 6.4 g and female 6.0 g in *ludovicae*. Male of nominate with frontlet glittering pale green, crown and nape dark coppery-bronze, shading to bronzy-green on back; uppertail-coverts blue, tinged grey-blue distally; tail black, narrowly tipped with dull grey; underparts dull, dark greenish bronze, darker and greener on throat. Female similar but frontlet usually smaller and sometimes lacking, underparts greyer on average, grey tips to rectrices usually broader. Race *veraguensis* smaller and more dichromatic; male darker.

dusky green below, darker bronze on crown and nape providing increased contrast with frontlet; female greyer below with more purplish bronze crown, paler grey tips to rectrices. Immature tends to be greyer below and with duller bronzy crown and reduced frontlet.

Habitat. Mid-strata and lower canopy of wet, epiphyte-laden cloudforest and humid forest in broken terrain, with male more often along ridges while female prefers ravines and gorges, particularly for nesting. Especially outside breeding season, often along forest edges and into tall second growth, sometimes down to shrub height. Mainly 750-2300 m (rarely to

2600 m) in Costa Rica and Panama, 900-2400 m in Colombia, in some areas descending to lower elevations outside breeding season.

Food and Feeding. In forest usually visits flowers of epiphytes with long, tubular, usually pendent corollas, including Ericaceae (*Satyria*, *Psammisia*, *Cavendishia*, *Macleania*), Loranaceae (*Psittacanthus*), Rubiaceae and Gesneriaceae, preferring to hover beneath flower without clinging (for which the slightly upturned bill is ideal); usually trap-lines dispersed clumps, but during breeding season male may defend rich clumps. Outside forest may visit flowers with short or long corollas, including many Rubiaceae, Gesneriaceae, etc. Frequently flycatches, sallying from perch in canopy or along stream, or hover-hawks, especially low over streams; also hover-gleans arthropods from vegetation.

Breeding. In Costa Rica breeds in latter half of wet season to start of dry, Aug-Jan; in Colombia nesting recorded between Jul and late Jan. Nest a rather bulky cup of moss, treefern scales, fine fibres and cobwebs in dark, usually humid site; generally attached to hanging rootlet or vine under rock overhang in dark ravine or gorge (in which case lower part often elongated to form a cylindrical structure) but sometimes attached to wire under bridge or roof; less often on small ledge in gorge or cave. Clutch 2; incubation (one nest) 19 days; fledging period 25+ days (young frightened by people, might have left 1-2 days later if undisturbed).

Movements. Outside breeding season in Costa Rica many individuals descend to 500 m, rarely down to 150 m on Caribbean slope; no information available on other populations.

Status and Conservation. Not globally threatened. CITES II. Generally uncommon to locally fairly common in suitable habitat throughout range, which includes several protected areas for both races, e.g. Tapanti National Park (Costa Rica), Río Nambi Reserve (Colombia) and Paschoa Forest Reserve (Ecuador). Will tolerate moderate disturbance caused by selective logging and forest fragmentation, and evidently can take advantage of remnant forest strips along streams as corridors for altitudinal movements.

Bibliography. Bond & Meyer de Schauensee (1943), Fjeldså & Krabbe (1990), Hilty (1997), Hilty & Brown (1986), Meyer de Schauensee & Phelps (1978), Remsen, Traylor & Parkes (1986), Ridgely & Gwynne (1989), Ridgway (1911), Ruschi (1961d), Salaman & Mazariegos (1998b), Slud (1964), Snow, B.K. & Gochfeld (1977), Snow, D.W. & Snow (1980), Stattersfield *et al.* (1998), Stiles (1985b), Stiles & Skutch (1989), Stotz *et al.* (1996), Wetmore (1968a), Williams & Tobias (1994), Zimmer (1950a).

37. Blue-fronted Lancebill

Doryfera johannae

French: Porte-lance de Jeanne **Spanish:** Colibrí Picolanza Menor
German: Blaustirn-Lanzettschnabel

Taxonomy. *Trochilus Johanna* Bourcier, 1847, Peru.

Genus formerly placed in subfamily Phaethornithinae, due largely to confusion regarding its nest; now known to be part of the basal radiation of the Trochilinae; in many older works generic name *Hemistephania* was used. Two subspecies recognized.

Subspecies and Distribution.

D. j. johannae (Bourcier, 1847) - E slope of E Andes from CE Colombia to NE Peru.

D. j. guianensis (Boucard, 1893) - S Guyana, S Venezuela and tepuis of adjacent N Brazil.

Descriptive notes. 10-11 cm; male 4.2 g, female 3.9 g. Long, very slender, slightly upturned bill with prominent tomial serrations and rather short, rounded tail are characteristic of genus. Male of nominate has frontlet violet, rest of upperparts dark bronzy-green, tinged dark bronze on nape; uppertail-coverts blue with duller tips, tail blue-black; underparts blue-black glossed with bluish green on throat and breast. Female with frontlet greenish blue, otherwise like male; lateral rectrices tipped with dull grey; underparts dull, greyish bronzy-green. Race *guianensis* differs in paler ventral colouring, less intensely violet forecrown of

male, and shorter bill. In female, frontlet usually almost or just as large as that of male but may be small or even absent altogether, apparently irrespective of age.

Habitat. In E Andes, prefers wet forests of lower mountain slopes, foothills and adjacent lowlands, especially in broken terrain with dark ravines, gorges and rocky outcrops; usually from mid-strata to lower canopy in forest but may descend to shrub level along forest edges and (females) to nest. At 400-1600 m in Colombia, most abundant at 800-1200 m. Race *guianensis* occurs disjunctly in upper tropical-subtropical forests on tepuis (table mountains), and not reported from intervening areas.

Food and Feeding. Hovers to visit hanging, tubular flowers of epiphytic Ericaceae (*Satyria*, *Psammisia*), Loranaceae (*Psittacanthus*) as well as horizontally oriented flowers of Rubiaceae, Gesneriaceae and other Ericaceae in lower canopy, along forest streams and at forest edge; not known to defend feeding territories at flowers. Regularly flycatches from perches in lower canopy, forest edge, tops of small trees, and along streams; may hover over streams making repeated dashes for prey in swarms of gnats, also (especially female) hover-gleans foliage and moss along streams.

Breeding. In E Ecuador, nest with 2 eggs Jul; one female in C Colombia with enlarged follicles in Sept. Only described nest E Ecuador. ■ cylindrical structure of moss and cobweb with nest cup at top, suspended from rock overhang in cave. No further information.

Movements. No information available; presumably sedentary, but may show some seasonal altitudinal movements.

Status and Conservation. Not globally threatened. CITES II. Its preferred foothill elevations have been severely deforested over much of Colombian range. Uncommon to fairly common in good forest habitat, but will tolerate some disturbance and occurs in selectively logged and fragmented forest and old secondary forest, albeit at lower abundance, along the Andes; common in cocoa plantations in Nariño (S Colombia). No information available on abundance of *guianensis*, but presumably not threatened, as considerable portions of habitat remain mostly intact; occurs in Imataca Forest Reserve (Venezuela).

Bibliography. Barrowclough *et al.* (1995), Butler (1979), Chubb (1916), Gilliard (1941), González (1998), Grantsau (1988), Hilty & Brown (1986), Mayr & Phelps (1967), Meyer de Schauensee (1949, 1964), Meyer de Schauensee & Phelps (1978), Ruschi (1974, 1986), Salaman & Mazariegos (1998b), Sick (1993), Snow & Gochfeld (1977), Snyder (1966), Stotz *et al.* (1996), Willard *et al.* (1991), Zimmer (1950a).

Genus *CAMPYLOPTERUS* Swainson, 1827

38. Scaly-breasted Hummingbird

Campylopterus curvipennis

French: Colibri de Cuvier **German:** Schuppenbrustkolibri **Spanish:** Colibrí de Cuvier
Other common names: Cuvier's Sabrewing, Cuvier's (Scaly-breasted) Hummingbird; Robert's Hummingbird (*roberti*)

Taxonomy. *Trochilus Cuvierii* DeLatte and Bourcier, 1846, east-central Panama.

Traditionally segregated in genus *Phaeochroa*, but the thickened, flattened shaft of the outer primary in adult male of this species is similar to that of other *Campylopterus*, and the coloration, behaviour and vocalizations of some of the dull-coloured, sexually monochromatic species of that genus also resemble present species. Race *roberti* sometimes given species status, based upon differences in bill and rectrix colour. Six subspecies normally recognized.

Subspecies and Distribution.

C. c. roberti (Salvin, 1861) - extreme SE Mexico, N Guatemala and Belize S on Caribbean slope to NE Costa Rica.

C. c. maculicauda (Griscom, 1932) - Pacific slope of Costa Rica.

C. c. furvescens Wetmore, 1967 - Pacific slope of W Panama.

C. c. saturator (Hartert, 1901) - Coiba I (Panama).

C. c. cuvierii (DeLatte & Bourcier, 1846) - E & C Panama.

C. c. berlepschi (Hellmayr, 1915) - coastal region of N Colombia.

Descriptive notes. 11.5-13 cm; male 10-1 g and female 8-6 g in *maculicauda*, male 9-3 g and female 7-9 g in nominate *cuvierii*. Mostly bronzy-green, with dull buffy borders on feathers of most of underparts imparting ■ scaly appearance; belly greyish-buff; corners of tail dull white, set off by diagonal blackish band from rest of bronzy tail. Female has longer bill on average but otherwise smaller than male, and does not differ in colour. Young bird lacks the thickened shafts of the outer primaries and has prominent buffy fringes on the feathers of the crown, nape and uppertail-coverts. Basal half of lower mandible

pinkish in most races, black in *roberti*; race *saturator* largest and darkest, nominate smallest and palest; *berlepschi* has belly more rusty, white on lateral rectrices more extensive; in *roberti* these rectrices are entirely black except for white tips; *maculicauda* has somewhat greener throat and more extensive black on outer rectrices; *furvescens* has throat and upper breast slightly darker green, belly paler.

Habitat. Dry forest, edges and clearings of gallery forest and humid forest, mangrove, second growth and scrub, fencerows, gardens and other more or less open habitats; avoids interior of closed evergreen forest. In dry forest and mangrove occurs from understorey to mid-strata, and to tree tops along edges. Mainly in lowlands but locally to 1200 m in SW Costa Rica.

Food and Feeding. Visits flowers of trees (*Genipa*, *Hibiscus*, *Pelliciera*, *Inga*, *Erythrina*), shrubs, terrestrial bromeliads (*Bromelia*) etc., for nectar, sometimes perching to probe large blooms; very aggressive, often territorial at rich feeding areas where dominant over smaller hummingbirds. Frequently flycatches from perches, also gleans foliage and bark of trees and shrubs for arthropods.

Breeding. Mainly during rainy season, May-Dec (Guatemala), May-Jan (Costa Rica). Nest a well-built cup of plant down and spiderweb, sometimes with fungal rhizomorphs, heavily decorated on outside with moss and lichen and often with lichen in lining; typically saddled on horizontal branch of small tree 2-8 m above ground. During breeding season males often in loose leks of up to 8 in canopy of second growth or low mangrove, or at forest edge. Clutch size 2; incubation 17-19 days; fledging period 22-26 days (to 29 days in inclement weather conditions); fledglings fed for up to 39 days after leaving nest.

Movements. Basically sedentary, but with more or less pronounced local movements in response to changes in flowering.

Status and Conservation. Not globally threatened. CITES II. Uncommon to locally common in most areas. Probably benefits from forest clearance in most areas, though some mangrove populations may be threatened by loss of habitat due to cutting of mangroves for shrimp culture, etc., especially in Central America. Occurs at Bonampak and Yaxchilán in N Chiapas (S Mexico), in Corcovado National Park and Carara Biological Reserve (Costa Rica), and on Atlantic side of Canal Area (Panama).

Bibliography. Anon. (1992a, 1998a), Hilty & Brown (1986), Howell, S.N.G. (1989a), Howell, S.N.G. & Webb (1995a), Howell, T.R. (1957), Land (1970), Monroe (1968), Olson (1997), Ridgely & Gwynne (1989), Ridgway (1911), Skutch (1964b, 1972, 1981), Slud (1960, 1964, 1980), Smith (1966), Stiles (1985c), Stiles & Skutch (1989), Stiles & Wolf (1970), Stotz *et al.* (1996), Wetmore (1957a, 1968a), Wolf (1970).

39. Wedge-tailed Sabrewing

Campylopterus curvipennis

French: Campyloptère pampa **German:** Blaukron-Degenflügel **Spanish:** Colibrí Ruiseñor
Other common names: Curve-winged Hummingbird/Sabrewing (*curvipennis*); Long-tailed/Tuxtla Sabrewing (*excellens*)

Taxonomy. *Trochilus curvipennis* Lichtenstein, 1830, Mexico.

In past, sometimes separated in genus *Pampa*. Race *excellens* considered by some to be full species; research required in zone of hypothetical contact. Race *pampa* has also been treated as separate species, based mainly on shorter bill, but behaviour and voice similar to those of nominate. Subpopulation of Yucatán Peninsula sometimes regarded as race *yucatanensis*, but doubtfully distinct. Three subspecies currently recognized.

Subspecies and Distribution.

C. c. curvipennis (Lichtenstein, 1830) - SE San Luis Potosí and SW Tamaulipas to N Oaxaca (SE Mexico).

C. c. excellens (Wetmore, 1941) - Sierra de Tuxtla (S Mexico).

C. c. pampa (Lesson, 1832) - Yucatán Peninsula S to N Guatemala and Belize; E Honduras.

Descriptive notes. 12-14 cm; male 9-2-12-7 g, female 5-9-8 g. Male has slightly decurved black bill; crown iridescent bluish-violet to purplish, rest of upperparts metallic green, postocular spot white; underparts grey; outer three primaries with thickened and flattened shafts, strongly decurved; tail long, graduated, bluish green. Female similar to male, shafts of primaries less prominent; tail shorter, less graduated, tipped white on outer rectrices. Immature resembles adult female with buffy feather tips. Race *excellens* is larger, with underparts paler and tail longer; *pampa* has shorter bill, darker grey below.

Habitat. Edges of humid to semi-arid evergreen forest, second growth open woodlands, and flowering gardens from sea-level to 1400 m, most commonly below 300 m. Forages in low to high strata.

Food and Feeding. Takes nectar and arthropods. No information on specific plants visited. Territorial.

Breeding. Little information available. Males in breeding condition have been reported Sept-May (*excellens*).

Movements. Sedentary with some apparent altitudinal movements.

Status and Conservation. Not globally threatened. CITES II. Locally common; seems to accept man-made habitats like edges of flowering gardens; not recorded near agricultural areas. Present at Gómez Fariás (Tamaulipas), El Naranjo (San Luis Potosí), Coatepec and Amatlán (Veracruz), Valle Nacional (Oaxaca), Palenque and Bonampak (N Chiapas) and Chichén Itzá (Yucatán). Race *excellens*, if considered full species, classified as Near-threatened and restricted-range species; present in Los Tuxtlas and Uxpanapa EBA.

Bibliography. Anon. (1998a), Edwards & Tashian (1959), Feinsinger (1976), Friedmann *et al.* (1950), González-García (1993), Howell & Webb (1995a), Johnsgard (1997), Klaas (1968), Land (1970), Lowery & Dalquest (1951), Monroe (1968), Nocolad (1981), Ridgway (1911), Russell (1964), Rutgers & Norris (1972), Smith (1966), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Stresemann (1954), Wetmore (1941, 1943), Winker, Ramos *et al.* (1992).

40. Grey-breasted Sabrewing

Campylopterus largipennis

French: Campyloptère à ventre gris **German:** Graubrust-Degenflügel **Spanish:** Colibrí Pechigrís
Other common names: Bronze-shafted/Tail-coated Sabrewing

Taxonomy. *Trochilus largipennis* Boddaert, 1783, Cayenne.

Four subspecies recognized.

Subspecies and Distribution.

C. l. aequatorialis Gould, 1861 - E Colombia, E Ecuador, E Peru and N Bolivia to NW Brazil.

C. l. largipennis (Boddaert, 1783) - E Venezuela, the Guianas and R Negro region of NW Brazil.

C. l. obscurus Gould, 1848 - E Pará and Maranhão (NE Brazil).

C. l. diamantinensis Ruschi, 1963 - Serra Espinhaço in Minas Gerais (SE Brazil).

Descriptive notes. 13-14.9 cm; male 9-10 g, female c. 8 g. Male has slightly decurved bill, upper mandible black, lower fleshy with black tip; upperparts dark shining green, postocular spot white; underparts uniform dark grey, shafts of outer three primaries thickened and flattened; tail graduated, central pair of rectrices green, remainder bluish black, distal half white. Female similar to male, shafts of primaries less prominent. Immature resembles adult female. Race *obscurus* is smaller, rectrices tipped grey; *aequatorialis* has only last portion of rectrices tipped white; race *diamantinensis* has outer rectrices larger, bronzy-green.

Habitat. Humid forest, second growth, clearings, plantations and thickets at 100-400 m; race *diamantinensis* has been recorded between 1200 and 1400 m. Forages at low to medium heights.

Food and Feeding. Feeds on nectar of flowering Ericaceae, *Heliconia* and other plants; in Nariño (S Colombia), feeds on bushes of Melastomataceae. Arthropods are caught in the air by hawking. Territorial.

Breeding. Birds in breeding condition in Jun (Colombia); one nest in Apr (Brazil). Cup-shaped nest is built out of moss, lined with soft seed material, exterior decorated with large pieces of lichen; saddled on horizontal branch or glued to hanging twigs near waterfalls, or in bushes low above running water. Clutch size 2; incubation and fledging periods unknown.

Movements. Sedentary.

Status and Conservation. Not globally threatened. CITES II. Uncommon to locally common. Accepts man-made habitats and other disturbed areas like plantations and clearings. Regularly

recorded at Imataca Forest Reserve (Venezuela); also at Timberhead Lodge (N Guyana); and at Tingo María (C Peru).

Bibliography. Balchin & Toyne (1998), Berlioz (1931b, 1964), Bond & Meyer de Schauensee (1943), Cotton (1998a), Friedmann (1948), Gounelle (1909), Grantsau (1988), Haverschmidt & Mee (1994), Hilty & Brown (1986), Meyer de Schauensee & Phelps (1978), Niethammer (1953), Ruschi (1950a, 1963b, 1964e, 1964f, 1973d, 1981-1982, 1986), Rutgers & Norris (1972), Salaman & Mazariegos (1998a, 1998b), Sick (1993, 1997), da Silva (1990), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Thérý (1987), Tostain *et al.* (1992), Willis (1976), Zimmer (1950b).

41. Rufous Sabrewing

Campylopterus rufus

French: Campyloptère roux

Spanish: Colibrí Rojizo Mexicano

German: Buntschwanz-Degenflügel

Taxonomy. *Campylopterus rufus* Lesson, 1840, no locality = Guatemala.

In past, sometimes separated in genus *Platystylopterus*. Possibly forms superspecies with *C. hyperythrus*. Monotypic.

Distribution. Pacific slope of Mexico (E Oaxaca, Chiapas), S Guatemala and El Salvador.

Descriptive notes. 12-5-14 cm; male c. 9 g, female 6-6-6-9 g. Male has medium-sized, slightly decurved black bill; upperparts iridescent bronzy-green, postocular spot white; underparts uniformly cinnamon; tail slightly rounded, central pair of rectrices golden-bronze, others light cinnamon with black subterminal band, edged cinnamon, outermost tail feather cinnamon with lighter edges. Female similar to male, smaller. Immature like adult, head feathers with buffy fringes.

Habitat. Rainforest and forest edge, canyons with scattered woods, humid pine-oak forests, plantations; occurs at 900-2000 m, occasionally fairly low in dense understorey and in semi-open terrain.

Food and Feeding. Nectar of flowering *Plantago*, *Erythrina*, *Salvia*, *Castilleja*. Insects are caught in the air by hawking. Male occupies feeding territories at nectar-rich sources.

Breeding. Apr-May (Oaxaca, Mexico). Male forms small leks. Cup-shaped nest of moss lined with whitish thistle down, externally decorated with lichen, rather exposed on horizontal branch, 1-2 m above the ground. Clutch size 2; incubation 15-16 days, by female; chick blackish with two rows of buffy dorsal down; fledging 23-26 days.

Movements. Sedentary, with local altitudinal wandering depending on flowering season.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species; present in North Central American Highlands EBA. Locally common. Readily accepts man-made habitats such as plantations or pastures with scattered shrubs and trees. Present at El Triunfo Biosphere Reserve (S Chiapas).

Bibliography. Anon. (1998a), Berlioz (1931b), Binford (1989), Dearborn (1907), Dickey & van Rossem (1938), Friedmann *et al.* (1950), Howell & Webb (1995a), Land (1970), Rowley (1984), Stotz *et al.* (1996), Thurber *et al.* (1987).

42. Rufous-breasted Sabrewing

Campylopterus hyperythrus

French: Campyloptère rougeâtre

Spanish: Colibrí Rojizo Venezolano

German: Rostbauch-Degenflügel

Other common names: Tepui Sabrewing

Taxonomy. *Campylopterus hyperythrus* Cabanis, 1848, Mount Roraima.

Possibly forms a superspecies with *C. rufus*. Often considered conspecific with *C. duidae*. Monotypic.

Distribution. Pantepui, on isolated table mountains in SE Venezuela and adjacent NW Brazil.

Descriptive notes. 12 cm; 5-6-5 g. Male has straight black bill; upperparts shining bronze-green, greener on head; underparts uniform cinnamon, shafts of outer three primaries thickened and flattened; four central tail feathers golden-bronze, outer ones cinnamon-rufous. Female similar to male. Immature resembles adult.

Habitat. Scrub on summits of low tepui (table mountains), highland saxicolous biomes, evergreen high tepui forests and upper montane forests at 1200-2050 m.

Food and Feeding. Forages alone on nectar and tiny arthropods in forest understorey and mid-strata.

Sánchez (1995), Sick (1993, 1997), Stattersfield *et al.* (1998), Stotz *et al.* (1996).

Breeding. No information available.

Movements. Sedentary.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species; present in Tepuis EBA. Although endemic to tepuis of Guayanian region it is a common species in those habitats and no immediate threat is known at present.

Bibliography. Bleiweiss (1990), Dunning (1982), Forrester (1993), Gilliard (1941), Grantsau (1988), Mayr & Phelps (1971), Medina (1992), Meyer de Schauensee (1982), Meyer de Schauensee & Phelps (1978), Olrog (1968), Phelps & Phelps (1958), Renjifo *et al.* (1997), Ruschi (1964f, 1981-1982, 1986),

43. Violet Sabrewing

Campylopterus hemileucurus

French: Campyloptère violet

German: Violettdegenflügel

Spanish: Colibrí Morado

Other common names: De Lattre's Sabrewing

Taxonomy. *Trochilus hemileucurus* Lichtenstein, 1830, Mexico.

Two subspecies recognized.

Subspecies and Distribution.

C. h. hemileucurus (Lichtenstein, 1830) - S Mexico patchily to SC Nicaragua.

C. h. mellitus Bangs, 1902 - Costa Rica and W Panama.

Descriptive notes. 13-15 cm; male 11-8 g, female 9-5 g. Bill black, more strongly decurved in female. In adult male shafts of outer two primaries strongly thickened, curved and flattened; much less so in adult female and young male and not at all in young female. Head, upper back and underparts of male violet-blue in nominate race, violet in *mellitus*; lower back dark green, broad tail with white outer edges. Female has dark green upperparts, grey underparts with violet gorget, tail as male. Young bird has prominent, dull buffy fringes to feathers of upper- and underparts; lacks violet; rectrices narrower and more pointed than those

of adult; young male dusky bluish-green below.

Habitat. Understorey and edges of humid forest in foothills and on mountain slopes, old second growth, forest patches in disturbed areas, gardens and small banana plantations near forest or woodland; female prefers ravines, and banks of rivers and streams for nesting. Mostly at 100-1500 m (S Mexico), 900-2400 m (Costa Rica, Panama).

Food and Feeding. Visits flowers mainly in understorey, especially *Heliconia*, also those of shrubs like *Cephaelis*, *Palicourea* (Rubiaceae) and banana (*Musa*), including ornamental species like *M. coccinea*. Male occasionally territorial at flowers, but on the whole less aggressive and dominant than large size might suggest. Forages for arthropods more by gleaning foliage and spiderwebs than by flycatching, taking many spiders as well as Diptera, Hymenoptera, etc.

Breeding. Mainly in rainy season, Jun-Sept (S Mexico), May-Oct (Costa Rica), Jul (El Salvador). Nest a bulky, well-constructed cup, mainly of green moss lined with fine fibres and plant down and held together with cobweb, placed on low, slender horizontal branch of small tree or bamboo, typically overhanging stream or ravine, 1-6 m above ground or water. During breeding season up to 10-12 males form leks. No further information.

Movements. Pronounced altitudinal movements in many areas, descending to lower elevations (locally to sea-level) outside breeding season.

Status and Conservation. Not globally threatened. CITES II. Common in many areas, and able to withstand much disturbance as long as some forest cover or tall second growth remains; can use remnant strips of forest along streams as corridors for local movements. Protected areas within range include Las Tuxtlas Biological Station in Mexico (*hemileucurus*), Monteverde Forest Preserve and several national parks in Costa Rica (*mellitus*).

Bibliography. Brown & Bowers (1985), Dickey & van Rossem (1938), Feinsinger (1976, 1977, 1980), Friedmann *et al.* (1950), Howell, S.N.G. & Webb (1995a), Howell, T.R. (1964), Hutto (1985), Johnsgard (1997), Lowery & Dalquest (1951), Monroe (1968), Navarro (1986), Ridgely & Gwynne (1989), Ridgway (1911), Skutch (1967), Slud (1964), Stiles (1979, 1985b), Stiles & Skutch (1989), Stotz *et al.* (1996), Tashian (1952), Thurber *et al.* (1987), Wagner (1946a, 1957b), Wetmore (1968a), Worth (1942).

PLATE 48

inches 2
cm 5

44. White-tailed Sabrewing

Campylopterus ensipennis

French: Campyloptère à queue blanche

Spanish: Colibrí Coliblanco

German: Weißschwanz-Degenflügel

Taxonomy. *Trochilus ensipennis* Swainson, 1822, no type locality given. Monotypic.

Distribution. NE Venezuela, in Cordillera de Caripe and mountains of Paria Peninsula; Tobago. Occurrence on Trinidad questionable; at present no definite records, and specimens collected in 1860, labelled "Trinidad" without exact locality data, may simply represent trade skins obtained on the island.

Descriptive notes. c. 13 cm; male 9.5-10.5 g, female presumably lighter. Male has black decurved bill; upperparts glittering green, postocular spot white; underparts glittering green with throat blue iridescent dark violet; shafts of outer three primaries thickened and flattened; tail squared, central rectrices dark bronzy-green, outer three tail feather pairs proximally black, distal two-thirds white. Female similar to male but underparts pale grey with green discs on flanks. Immature resembles adult female.

Habitat. Montane forest, old second growth, tree-fall gaps, and plantations, at 400-2000 m.

Forages in low and middle strata.

Food and Feeding. Feeds on nectar of flowering bromeliads, *Heliconia*, *Palicourea* and banana (*Musa*). Insects are caught in the air by hawking, typically from a number of adjacent perches; territorial, though recent work suggests territories are related to breeding, not feeding.

Breeding. Two nests on Tobago in Feb; nest cup-shaped, large, made mainly of moss, saddled on horizontal branch, in fork, or attached to ends of hanging twigs; in shrubs, 1.7-2.5 m above ground or running water. Clutch size 2; incubation by female. No further information.

Movements. No information. Some altitudinal dispersal most likely.

Status and Conservation. VULNERABLE. CITES II. Restricted-range species; present in Caripe-Paria Region EBA. Rare to locally common. Habitat destruction is main threat. On Tobago, population suffered severely from 1963 hurricane "Flora" which destroyed most of the forest on the island, with only small patches remaining; only a few individuals recorded in 1974/75 that survived in remaining forest area; today forest is slowly regenerating and population on Tobago seems to be stable or slightly increasing. In Venezuela, deforestation of suitable habitat for agricultural purposes is main threat; slash-and-burn destruction for cash-crop cultivation occurs widely. Although seems to accept slightly disturbed areas like coffee plantations, has never been recorded in strictly agricultural areas. Only some remote forest patches are still pristine, mainly on E end of Paria Peninsula; these patches are presently threatened by a pipeline project across the peninsula known as "Proyecto Colón". Occurs in Paria Peninsula National Park, where fairly common, and recorded density in this region is at least 1.5 pairs/km²; also occurs in Cueva del Guácharo National Park, where is apparently one of the commoner birds, present all year.

Bibliography. Anon. (1989b), Belcher & Smoother (1936), Berlioz (1931b), Bond *et al.* (1989), Chapman (1925b), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), French (1991), Hayes (1996), Hayes, Bullard *et al.* (1995), Hayes, Garnett, Bernard, Bullard *et al.* (1997), Hayes, Garnett, Bernard & Samad (1997), Herklots (1961), Jouanin (1946), Junge & Mees (1958), Meyer de Schauensee & Phelps (1978), Murphy (1991), Paynter (1982), Phelps & Phelps (1958), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Thelen & Faizol (1980), Wege & Long (1995).

45. Lazuline Sabrewing

Campylopterus falcatus

French: Campyloptère lazulite

German: Rotschwanz-Degenflügel

Spanish: Colibrí Lazulita

Taxonomy. *Trochilus falcatus* Swainson, 1821, northern Venezuela.

In past, sometimes placed in genus *Saeptiopterus*. Monotypic.

Distribution. Coastal ranges of NC Venezuela down E slope of Andes to NE Ecuador.

Descriptive notes. 11.5-13 cm; c. 7.6 g. Male has black decurved bill; upperparts glittering green, blue on crown; throat and breast glittering dark violet-blue shading to glittering blue, green on belly, shafts of outer three primaries thickened and flattened; tail feathers chestnut, central pair broadly tipped bronze-green. Female similar to male, also with white postocular spot; throat glittering bluish, rest of underparts plain grey, flanks with green discs, tail similar to that of male but often with more green on central rectrices. Immature resembles adult female.

Habitat. High and low montane semi-deciduous forest, flowering gardens, plantation edges and sub-*páramo*, at 900-3000 m.

Food and Feeding. Feeds on nectar of flowering Ericads, *Heliconia*, *Hibiscus* and other flowers. Arthropods are caught in the air and gleaned from foliage. Forages in understorey and mid-strata of forest. Reported to drink water stored in *Heliconia* bracts.

Breeding. Birds in breeding condition in June, Perijá mountains, Colombia/Venezuela. No further information.

Movements. No precise information; presumably sedentary.

Status and Conservation. Not globally threatened. CITES II. Uncommon and patchily distributed in montane evergreen forests of N Andes. Relatively sensitive to some habitat changes, but readily accepts man-made habitats like flowering gardens and plantations. Occurs at Colonia Tovar, near Caracas (N Venezuela); also near San Andrés de Pisimbalá (SC Colombia).

Bibliography. Best *et al.* (1997), Bleiweiss (1990), Butler (1979), Chapman (1926), Dunning (1982), Ejlsdál & Krabbe (1990), Hilty & Brown (1986), Meyer de Schauensee (1982), Meyer de Schauensee & Phelps (1978), Miller (1952), Olog (1968), Phelps & Phelps (1958), Rutgers & Norris (1972), Sánchez (1995), Stotz *et al.* (1996).

46. Santa Marta Sabrewing

Campylopterus phainopeplus

French: Campyloptère des Santa Marta

Spanish: Colibrí de Santa Marta

German: Santa-Marta-Degenflügel

Taxonomy. *Campylopterus phainopeplus* Salvin and Godman, 1879, Santa Marta Mountains, Colombia.

In past, sometimes placed in genus *Saeptiopterus*. Monotypic.

Distribution. NE & S slopes of Santa Marta Mts (NE Colombia).

Descriptive notes. c. 13 cm. Male has slightly decurved black bill; upperparts glittering emerald-green, postocular spot white, face black; throat and breast iridescent blue, rest of underparts dark green, shafts of outer three primaries thickened and flattened; tail squared, dark steely blue. Female upperparts shining green; below greyish-white with green flanks and undertail-coverts; tail mainly green with outer rectrices tipped greyish. Immature resembles adult female.

Habitat. Borders of humid forest, plantations, especially old banana plantations, sometimes in bushy *páramo* up to snow-line, at 1200-4800 m.

m. Forages in lower strata.

Food and Feeding. Takes nectar and insects; no specific food plants recorded, except flowering banana (*Musa*); territorial.

Breeding. Birds in breeding condition Apr-Jun, displaying males Jun-Jul. No further data available.

Movements. Seasonal altitudinal movements at lower elevations (1200-1800 m) during dry season (Feb-May), higher, occasionally up to snow-line (4800 m), during wet season (Jun-Oct).

Status and Conservation. Not globally threatened. CITES II. Currently considered Near-threatened. Restricted-range species; present in Santa Marta Mountains EBA. Locally common but restricted in range. Readily accepts man-made habitats like banana plantations. Most of distributional range cannot be visited safely resulting in lack of life-history data.

Bibliography. Berlioz (1931b), Ejlsdál & Krabbe (1990), Hilty & Brown (1986), Meyer de Schauensee (1982), Olog (1968), Renjifo *et al.* (1997), Salaman & Mazariegos (1998a), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Todd & Carriker (1922).

47. Napo Sabrewing

Campylopterus villaviscensio

French: Campyloptère du Napo

German: Napodegenflügel

Spanish: Colibrí del Napo

Other common names: Splendid/Villaviscensio Sabrewing

Taxonomy. *Trochilus Villaviscensio* Bourcier, 1851, Napo, Ecuador.

In past, sometimes placed in genus *Saeptiopterus*. Monotypic.

Distribution. Tropical and subtropical S Colombia, E Ecuador and NE Peru.

Descriptive notes. c. 13.5 cm; male 7.4-9.3 g, female 5.2-7.4 g. Male has almost straight black bill; crown glittering golden green, postocular spot white, rest of upperparts bronzy-green; throat and chest dark violet-blue, rest dark grey with green discs, shafts of outer three primaries thickened and flattened; tail slightly forked, dark blue, with central rectrices bronze-green. Female emerald-green above; underparts grey; tail forked, blue-green, outer rectrices tipped whitish-grey. Immature resembles adult female.

Habitat. Montane humid forest at 1000-1800 m; found at 780 m in Nariño (S Colombia). Forages in low to medium strata.

Food and Feeding. Feeds on nectar, presumably of flowering *Heliconia*, bromeliads and other plants; insects are caught in the air by hawking.

Breeding. Birds in breeding condition Oct-Nov; no further data available.

Movements. Unknown.

Status and Conservation. Not globally threatened. CITES II. Currently considered Near-threatened. Restricted-range species; present in Ecuador-Peru East Andes EBA. Locally common but habitat partly under threat of deforestation; does not seem to accept man-made habitats. Regularly recorded on Loreto road between Tena and Coca (NE Ecuador). Only recently (1998) discovered to occur in S Colombia, in Nariño and Putumayo. Research required.

Bibliography. Bulchin & Toyne (1998), Berlioz (1931b), Best *et al.* (1997), Butler (1979), Davis (1986), Meyer de Schauensee (1966, 1982), Olog (1968), Salaman & Mazariegos (1998a, 1998b), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Zimmer (1950b).

48. Buff-breasted Sabrewing

Campylopterus duidae

French: Campyloptère montagnard

German: Tepuidegenflügel

Spanish: Colibrí del Duida

Other common names: Duida Sabrewing

Taxonomy. *Campylopterus duidae* Chapman, 1929, Mount Duida, Venezuela.

In past, sometimes placed in monospecific genus *Loxopterus*. Often considered conspecific with *C. hyperythrus*. Proposed race *zuloagae* (S Venezuela) is considered a synonym of nominate. Two subspecies recognized.

Subspecies and Distribution.

C. d. guaiquinimae Zimmer & Phelps, 1946 - Mt Guaiquinima (S Venezuela).

C. d. duidae Chapman, 1929 - S Venezuela and adjacent N Brazil.

Descriptive notes. 12 cm. Very similar to *C. hyperythrus*; male has straight black bill; upperparts shining bronze-green, greener on head; underparts drab, tinted with tawny on sides, shafts of outer three primaries thickened and flattened; outer tail feathers have dull bronze basal portion. Female similar to male. Immature resembles adult female. Race *guaiquinimae* differs slightly in tone of upperparts, and in darker tail.

Habitat. In forested foothills and lower evergreen montane forests, and in low and high tepui (table mountain) scrub at 1220-1700 m.

Food and Feeding. Forages on nectar and tiny

spiders and insects in forest understorey and mid-strata.

Breeding. Nests placed 2-3 m above the ground. No further information.

Movements. Sedentary.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species: present in Tepuis EBA. Although endemic to tepuis of Guayanian region it is common in those habitats; no immediate threat recorded.

Bibliography. Barrowclough *et al.* (1995), Bleiweiss (1990), Dunning (1982), Forrester (1993), Grantsau (1988), Mayr & Phelps (1967), Meyer de Schauensee (1982), Meyer de Schauensee & Phelps (1978), Oltrog (1968), Phelps & Phelps (1958), Renjifo *et al.* (1997), Ruschi (1964f, 1981-1982, 1986), Sánchez (1995), Sick (1993, 1997), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Willard *et al.* (1991), Zimmer & Phelps (1946).

49. Sombre Hummingbird

Campylopterus curvipennis

French: Colibri vert et gris

German: Erzkolibri

Spanish: Colibrí Apagado

Taxonomy. *Trochilus curvipennis* Vieillot, 1818. Rio de Janeiro.

Formerly placed in monospecific *Aphantochroa*, but external morphology and flattened and thickened shafts of outer primaries may justify recent placement within *Campylopterus*, though systematic relationships still uncertain. Monotypic.

Distribution. E Brazil, from Goiás and Pernambuco to Mato Grosso and Rio Grande do Sul.

Descriptive notes. c. 12 cm; c. 9 g. Male has slightly decurved black bill; upperparts bronzy-green to blackish bronzy-green, postocular spot white, uppertail-coverts with slight coppery sheen; underparts dull grey, some dull green discs on throat; shafts of outer primaries slightly thickened and flattened; tail squared, central rectrices shiny green, remainder black with some bronzy gloss. Female similar, slightly smaller. Immature resembles adult.

Habitat. Edges and understorey of humid forest, plantations.

Food and Feeding. Feeds on nectar of flowering

er bromeliads, *Heliconia* and other plants. Arthropods caught in the air by hawking.

Breeding. Nov-Mar; nest is cup-shaped, built of soft plant material decorated with large pieces of lichen on the outside, saddled on horizontal branch. Clutch size 2; incubation by female 15-16 days; fledging period 28 days.

Movements. Sedentary.

Status and Conservation. Not globally threatened. CITES II. Common to locally common throughout its range. Commonly seen along Graciosa Road near Morretes, Paraná, SE Brazil, with density of at least 1-2 pairs/km². Occurs in Serra dos Órgãos and Itatiaia National Parks (Rio de Janeiro) and Parque Estadual da Pedra Talhada (Alagoas).

Bibliography. de Almeida & Ruschi (1976), Belton (1984), Forrester (1993), Gonzaga *et al.* (1995), Grantsau (1988), Oniki (1996), Pacheco *et al.* (1996), Parker & Goerck (1997), do Rosário (1996), Ruschi (1949b, 1964f, 1976d, 1981-1982, 1986), Sargeant (1996), Scott & Brooke (1985), Sick (1993, 1997), Sick & Teixeira (1981), Stotz *et al.* (1996), Tobias *et al.* (1993), Willis (1992).

50. Swallow-tailed Hummingbird

Campylopterus macrourus

French: Colibri hirondelle

German: Blauer Gabelschwanzkolibri

Spanish: Colibrí Golondrina

Other common names: Common/Brazilian Swallowtail, Cayenne Forktailed Hummingbird

Taxonomy. *Trochilus macrourus* J. F. Gmelin, 1788, Jamaica; error = Cayenne.

Formerly placed in monospecific genus *Eupetomena*; shape structure and enlarged shaft of primary in male support present treatment in *Campylopterus*. Nominant and race *simoni* intergrade in C Brazil (C Goiás, W & C Minas Gerais). Five subspecies recognized.

Subspecies and Distribution.

C. m. macrourus (J. F. Gmelin, 1788) - the Guianas and N, C & SE Brazil (Amapá and Pará; Mato Grosso, Goiás and Minas Gerais to São Paulo) to Paraguay.

C. m. simoni (Hellmayr, 1929) - NE Brazil (S Maranhão, Piauí, Ceará, Pernambuco and Bahia to C Goiás and C Minas Gerais).

C. m. cyanoviridis (Grantsau, 1988) - SE Brazil (Serra do Mar in S São Paulo).

C. m. hirundo (Gould, 1875) - E Peru (Huiro).

C. m. bolivianus (Zimmer, 1950) - NW Bolivia (Beni).

Descriptive notes. 15-17 cm (including bill of 2.1 cm, tail 7.9 cm); male 8-9 g, female 6-7 g. Male has slightly curved black bill; head, throat and breast deep violet-blue; upperparts and underparts blue-green or shining bronzy-green; tail deeply forked, blue. Female like male but smaller and duller. Immature like female but with brown-tinged feathers on head and neck. Race *simoni* with

bluish green on back and underparts; *hirundo* has head and throat dull cobalt-blue, tail less deeply forked; *cyanoviridis* has head, throat and breast shining blue-green, back and underparts golden bronzy-green; *bolivianus* has head greenish, contrasting with green on back, all colours very clear and bright.

Habitat. Open savanna-like vegetation with shrubs and trees, man-made habitats such as gardens, parks and plantations, also primary forest and forest edges. Common from sea-level to 1500 m. Forages from mid-strata to tree tops.

Food and Feeding. Nectar of native and introduced flowering trees, including Leguminosae, Malvaceae, Bombacaceae, Rubiaceae, Myrtaceae; epiphytic bromeliads and gesneriads. Defends nectar-rich resources. Feeds on insects in the air.

Breeding. Oct-Mar, also Jun in state of São Paulo. Cup-shaped nest is constructed on thin horizontal twigs of shrub or tree, usually at 1-3 m, but nests have also been found high in trees at 10-15 m. Nest material consists of fine plant fibre inside, moss and lichen outside. Clutch size 2; incubation 15-16 days, by female; chick dark with sparse, dark grey dorsal down; fledging 22-24 days; young return to nest during the first few nights and remain with adult female for 2-3 weeks. First breeding in second year.

Movements. Short-distance N-S migrant in Brazil.

Status and Conservation. Not globally threatened. CITES II. Rare in the Guianas. Common resident in Brazil, with densities of at least 3-6 individuals/km² in parks of large cities, such as São Paulo and Campinas; occurs in Serra da Canastra, Serra do Cipó and Brasília National Parks. Ready occupation of man-made habitats suggests that habitat loss is unlikely to be a problem. Trapping for wild-bird trade was significant until 1970 but has now ceased.

Bibliography. Genus FLORISUGA Bonaparte, 1850

51. White-necked Jacobin

Florisuga mellivora

French: Colibri jacobin

German: Weißnackenkolibri

Spanish: Colibrí Nuquiblanco

Other common names: (Great) Jacobin/White-bellied(!)/Collared Hummingbird

Taxonomy. *Trochilus mellivorus* Linnaeus, 1758. India; error = Surinam.

Over the wide continental range of this species several races have been named, but all are now lumped into nominate; only birds on Tobago, distinguishable by larger size, are generally separated, although some birds from Santa Marta Mts (NE Colombia) are apparently as large. For this race the name *tobagensis* is a frequently used synonym. Two subspecies recognized.

Subspecies and Distribution.

F. m. mellivora (Linnaeus, 1758) - S Mexico to Panama and Colombia, S to W Ecuador, SE Peru and N Bolivia, and E to Venezuela, Trinidad, the Guianas and Amazonian Brazil.

F. m. flabellifera (Gould, 1846) - Tobago.

Descriptive notes. 11-12 cm; male 7-4 g, female 6-5 g. Bill and feet black. Adult male with head and chest blue, broad white crescent on nape; rest of upperparts bright green including elongated uppertail-coverts; belly and most of tail white, narrowly edged and tipped black. Plumage of adult female notoriously variable, apparently individually; perhaps half to two-thirds show the "typical" female plumage with blue-green breast heavily scaled with whitish, belly dull white, upperparts entirely green and tail mostly green with dark blue tip, outer rectrix with white outer edge and tip; the remainder have plumage more or less male-like

with a few only distinguishable from adult male by their longer bills and shorter wings and tails (though overlaps exist in all measurements). Adult female may show plumages resembling those of immature as well as adult male. Proportions of male-like females may also vary geographically; much more study required. In young male, plumage varies from essentially female-like, but with more white in the tail, to male-like with more black in the tail; both female and young male sometimes show buffy stripes on malars and centre of rump; young female similarly variable but usually with less white in tail, often more bronzy on throat and chest. Race *flabellifera* larger.

Habitat. Humid forest canopy and borders, nesting in understorey; semi-open habitats of various types, e.g. lighter woodland, coffee and cacao plantations; tall second growth; and gallery forest. Usually high in trees, lower at edges and clearings. Occurs from sea-level up to c. 900 m; rarely, perhaps seasonally, up to 1500 m or more.

Food and Feeding. Visits flowers of a variety of trees, including *Inga*, *Vochysia*, *Erythrina*, *Bauhinia* and *Symphonia*, epiphytes (*Norantea*, *Columnnea*, bromeliads), shrubs and *Heliconia* along edges and in clearings. Many concentrate at flowering trees, where they are aggressive but infrequently territorial; also at *Heliconia*. Both sexes hawk flies for long periods, hovering and darting high above streams and clearings, or sallying from tree-top perches; less often glean foliage, female sometimes in understorey. Arthropod food mainly small Diptera and Hymenoptera, some individuals recorded taking ants.

Breeding. Dry to early wet seasons: Jan-Jun or Jul in Costa Rica and Panama; Feb-May in NW Colombia, Jun and Nov in E Colombia. Nest a rather shallow soft, felted cup of light-coloured plant down and cobweb, on flat upper surface of broad leaf of understorey palm (*Geonoma*, *Asterogyne*), where sheltered from above by another such leaf, 1-3 m above ground, sometimes near a stream. During breeding season chases and displays by male-plumaged birds noted in canopy and along edges, but not known to form leks. No further information.

Movements. Not well understood. In many areas reported to be common during some seasons, rare to absent in others, but no clear patterns evident on present information. Nominate casual or accidental on Aruba and the Grenadines (Carriacou).

Status and Conservation. Not globally threatened. CITES II. Uncommon to common, at least seasonally, over most of its broad range and appears well able to use disturbed and man-made habitats such as tree plantations. Occurs regularly within many protected areas, including Corcovado National Park (Costa Rica), Los Katíos and Amacayacu National Parks (Colombia), Guatopo and Sierra Nevada National Parks (Venezuela), Asa Wright Nature Centre (Trinidad) and Serra dos Orgãos National Park (Brazil).

Álvarez del Toro (1980), Barrowclough *et al.* (1995), Blake (1958), Bond & Meyer de Schauensee (1943), Brown & Bowers (1985), Cotton (1998a), Elgar (1978), Feinsinger (1980), Feinsinger *et al.* (1985), Iffrench (1991), Figueroa *et al.* (1998), Friedmann (1948), Friedmann *et al.* (1950), Grantsau (1988), Gyldestolpe (1945b), Haverschmidt & Mees (1994), Herklots (1961), Hilty (1997), Hilty & Brown (1986), Howell & Webb (1995a), Johnsgard (1997), Lowery & Dalquest (1951), Meyer de Schauensee & Phelps (1978), Monroe (1968), Nocedal (1981), Pople *et al.* (1997), Ridgely & Gwynne (1989), Ridgway (1911), Ruschi (1949a, 1981-1982, 1986), Rutgers & Norris (1972), Sick (1993, 1997), Slud (1960, 1964), Snow & Snow (1972), Snyder (1966), Stiles (1980, 1985b, 1995b), Stiles & Skutch (1989), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Tostain *et al.* (1992), Wetmore (1968a), Willis (1976), Zimmer (1950b).

52. Black Jacobin

Florisuga fusca

French: Colibri demi-deuil **German:** Schwarzkolibri **Spanish:** Colibrí Negro

Other common names: Pied/Dusky/White-tailed Jacobin

Taxonomy. *Trochilus fuscus* Vieillot, 1817, Brazil.

Traditionally placed in monospecific *Melanotrochilus*; inclusion in *Florisuga* based on voice, morphology, anatomy and reproductive behaviour. Monotypic.

Distribution. E Brazil (Rio Grande do Norte to Rio Grande do Sul) to SE Paraguay, NE Argentina and N Uruguay.

Descriptive notes. 12-13 cm; male 9 g, female 7 g. Sexes alike; immature plumage has sometimes been erroneously attributed to adult female. Bill straight, black; back and underparts black; lower back, uppertail-coverts and upperwing-coverts shining bronze-olive; flanks white; central tail feathers

black, the rest white tipped black. Immature has broad cinnamon band on sides of throat; feathers on back fringed chestnut; underparts black with varying amount of brown spots, flanks and lower belly white; tail black, except outermost feathers which are white.

Habitat. Frequently found in woodlands, gardens and mixed plantations with tall trees, from sea-level to 1400 m. Forages from lower to upper strata and at forest edge.

Food and Feeding. Searches for nectar at native and introduced shrubs and trees, including *Hibiscus*, *Eugenia*, *Eucalyptus*, *Erythrina*, *Calliandra*, *Dombeya*. In Rio Grande do Sul, in

Jul, congregations of more than 50 individuals have been observed feeding on the pink flowers of *Dombeya wallichii* (Sterculiaceae). Feeds on insects in the air, or gleans from leaves and spider webs.

Breeding. Aug-May. Nest is cup-shaped, of fine plant fibre and cobweb attached to mid-rib of strong large horizontal leaf in shrub or tree at 1-4 m. Clutch size 2; incubation 16-17 days, by female; chick is black with some grey dorsal down; fledging period 22-25 days; young remain with female for 3-4 weeks. Up to 2 broods raised per year. First breeding in second year.

Movements. Migratory. Appears in Rolândia, Paraná, SE Brazil Mar/Apr and leaves Sept; disappears from Rio de Janeiro May/Jun and returns Oct; in Rio Grande do Sul large aggregations of 40 to 60 individuals observed Jul. Phenology of migration pattern poorly understood.

Status and Conservation. Not globally threatened. CITES II. Common resident throughout Brazilian range. Occurs in Itatiaia National Park (Brazil). Ready occupation of man-made habitats suggests that habitat loss is unlikely to be a problem. Trapping for wild bird trade was significant until 1970's but has now apparently ceased.

Bibliography. Bech *et al.* (1997), Belton (1984), Canevari *et al.* (1991), Colmán & Pérez (1991), Flores (1995), Forrester (1993), Grantsau (1988), Hayes (1995), Jouanin (1949), Lamm (1948), Lowen, Clay *et al.* (1997), Mengel (1960), Narosky (1979), Oniki (1996), de la Peña (1994), do Rosário (1996), Ruschi (1952, 1973d, 1981-1982, 1982a, 1982c, 1986), Rutgers & Norris (1972), Sagot (1998b), Saibene *et al.* (1996), Sick (1993, 1997), Snow & Snow (1986), Snow & Teixeira (1982), Steinbacher (1936), Stotz *et al.* (1996), Tobias *et al.* (1993), Willis (1992), Wittmann (1982).

PLATE 49

inches 2
cm 5

Genus *COLIBRI* Spix, 1824

53. Brown Violet-ear

Colibri delphinae

French: Colibri de Delphine German: Brauner Veichenohrkolibri Spanish: Colibrí Pardo

Taxonomy. *Ornismya Delphinae* Lesson, 1839, no locality = Santa Fé de Bogotá, Colombia. Proposed race *greenwalti* of Bahia (E Brazil), claimed to differ very subtly in coloration, does not appear sufficiently distinct to merit recognition. Monotypic.
Distribution. Guatemala and Belize to Colombia, then S to W Ecuador, E Peru and N Bolivia, and E to Venezuela, Trinidad, Guyana and NC Brazil (Roraima); E Brazil (Serra Sincorá in Bahia).

Descriptive notes. 11-12 cm; male 6-9 g, female 6-1 g (Costa Rica). Sexes similar in coloration but male averages larger in all dimensions except bill length. Adult mainly dull greyish brown, glossed with green on the back; uppertail-coverts dusky, broadly edged with cinnamon; tail bronze-green with greenish black subterminal band, narrow ochraceous to greyish tip; violet patch from below eye to auriculars; lores and broad malar stripe buffy-white; centre of throat glittering green, to blue at lower edge; bill black, feet dark grey. Young bird differs from adult in showing broad cinnamon-buff to dull rufous borders to most of dorsal feathers and in having the blue-violet auricular patch largely or entirely replaced by darkish grey.

Habitat. Canopy and edges of humid forest, tall second growth, semi-open habitats like coffee plantations and shrubby clearings. Usually high in trees, but descends to shrub level along edges and at gaps and clearings. Prefers hilly country and lower mountain slopes, though descends to adjacent lowlands occasionally or seasonally. Recorded at 100-1600 m (Costa Rica), 100-2800 m (Colombia), 300-2000 m (Venezuela).

Food and Feeding. Visits a variety of flowers, usually those with short corollas (or nectariferous bracts) including those of trees (*Inga*, *Erythrina*, *Calliandra*, *Clusia*, *Warszewiczia*), epiphytes (especially Marcgraviaceae), vines (*Gurania*) and shrubs (*Cephaelis*, *Stachytarpheta*); aggressive, typically dominating smaller hummingbirds, but usually not territorial at flowers. Regularly hawks small flying insects by sallying from perch or hovering and darting high in air at breaks in canopy or low over streams.

Breeding. Late wet and early dry seasons: Nov-May in Costa Rica; Dec-Jan in E Venezuela; Nov and Apr in Colombia. Males form leks in canopy, usually 3-8 males at intervals of 30-60 m along ridgetop or forest edge. Nest a small cup of plant down saddled on twig of small shrub under bamboo, average 1-2 m above ground (Trinidad).

Movements. In most areas breeds mainly above 500-900 m, descending to lower elevations outside breeding season.

Status and Conservation. Not globally threatened. CITES II. Scarce, or at least infrequently recorded, over most of broad range, but locally common in some areas: freely uses altered or man-made habitats like second growth and coffee plantations.

Bibliography. Barrowclough *et al.* (1997), Belcher & Smoother (1936), Bloch *et al.* (1991), Elgar (1977, 1982a), Feinsinger (1976, 1980), ffrench (1991), Grantsau (1988), Haverschmidt & Mees (1994), Herklots (1961), Hilty (1997), Hilty & Brown (1986), Howell & Webb (1992a, 1995a), Junge & Mees (1958), Meyer de Schauensee & Phelps (1978), Monroe (1968), Murphy (1991), Perry *et al.* (1997), Rasmussen *et al.* (1996), Ridgely & Gaulin (1980), Ridgely & Gwynne (1989), Ridgway (1911), Ruschi (1981-1982, 1986), Rutgers & Norris (1972), Sick (1993, 1997), Slud (1960, 1964), Snyder (1966), Stiles (1985b), Stiles & Skutch (1989), Stotz *et al.* (1996), Wetmore (1968a), Zimmer (1950d).

54. Green Violet-ear

Colibri thalassinus

French: Colibri thalassin German: Kleiner Veichenohrkolibri Spanish: Colibrí Verdemar
Other common names: Mexican Violet-ear (*thalassinus*); Mountain Violet-ear (*cyanotus*)

Taxonomy. *Trochilus thalassinus* Swainson, 1827, Tamasalcátepec, state of Mexico, Mexico. The three southern races have sometimes been considered a separate species, *C. cyanotus*. Formerly recognized race *minor* of Honduras and Nicaragua is now usually subsumed into nominate; *cyanotus* and *crissalis* apparently intergrade through Colombia and Ecuador, and their distinctness has been questioned. Four subspecies currently recognized.

Subspecies and Distribution.

- C. t. thalassinus* (Swainson, 1827) - C & S Mexico to NC Nicaragua.
- C. t. cabanidis* (Heine, 1863) - Costa Rica and W Panama.
- C. t. cyanotus* (Bourcier, 1843) - mountains of Venezuela, Colombia and Ecuador.
- C. t. crissalis* Todd, 1942 - Andes of Peru and Bolivia, and extreme NW Argentina.

Descriptive notes. 10.5-11.5 cm; male 5-7 g, female 4-8 g. Plumage mostly a rather bluish green, with subterminal blue-black band on tail and broad violet patch from below eye to auriculars; feathers of throat and chest glittering green with darker centres; undertail-coverts edged with buff; bill and feet black. Male averages larger than female in all measurements except bill length; area of throat and breast with glittering green feathering is brighter and more extensive. Young birds lack the glittering green feathering below, the feathers being bronzy-green with narrow buff fringes; feathers of crown, nape and rump have narrow dull rufous fringes, and violet auricular patch (and that of the chest in nominate) are reduced or absent. Nominat differs from other races in having violet-blue patch on chest, although race *cabanidis* sometimes shows some blue on chest; nominate sometimes has chin blue, and bill is noticeably slimmer; race *crissalis* differs from *cyanotus* in having slightly paler underparts and little or no green in feathers of undertail-coverts, which are nearly uniform pale buff.

Habitat. Open, shrubby mountain slopes and highland pastures with scattered trees, forest edge adjoining highland scrub, landslide scars, streams, penetrating locally into forest understorey; hedgerows, second growth, coffee plantations, shady gardens. In most areas at 1200-3000 m, outside breeding season down to 500-1000 m locally.

Food and Feeding. Visits flowers of a variety of herbs (*Salvia*, *Lobelia*, *Cirsium*), shrubs (*Centropogon*, *Cephaelis*, *Besleria*, *Cuphaea*, *Stachytarpheta*), epiphytes (*Columnnea*, bromeliads), trees (*Inga*, *Clusia*, *Erythrina*), usually foraging at shrub height but perching fairly

high in trees, often overlooking flowers. Aggressive and sometimes territorial at flowers, but often subordinate to hummingbirds of similar or even smaller size. Frequently sallies from high, exposed perches to capture flies and gnats, or may make repeated darts while hovering, usually well above ground; less often gleans foliage at all heights along edges.

Breeding. Mainly late wet to dry seasons, Jul-Nov (C Mexico), Sept or Nov-Mar (Guatemala), Sept-Jan (El Salvador), Oct-Mar (Costa Rica), Mar-Aug (Colombia). During breeding season males sometimes solitary but more often in loose leks of up to 5. Nest a usually subterminal cup of tree-fern scales, plant down, dry grass blades and/or moss, held together with cobweb, lined with soft plant down, and diversely decorated on the outside with bits of bark, moss, lichen or dead leaves, on downward-drooping twig, rootlet, bamboo stem or fern, usually beside some opening like a road, stream or clearing, 1-3 m above ground. Clutch size 2; incubation 16-17 days; fledging period 23-25 days, to 28 days or more in inclement weather.

Movements. No long-distance migrations have been documented, but in most areas moves to lower elevations outside breeding season. Nominat race strays to extreme SW USA.

Status and Conservation. Not globally threatened. CITES II. Locally common to abundant over most of its wide range; has probably benefited from deforestation and habitat alteration in many areas. Present in Volcán Irazú and Volcán Poás National Parks (Costa Rica); also frequently recorded at Tamasalcátepec, Volcán de Fuego, Sierra de Atoyac and Lagos de Montebello (Mexico), Fortuna and Cerro Colorado (Panama), Colonia Tovar, near Caracas (Venezuela), and between Loja and Zamora (Ecuador).

Bibliography. Baepier (1962), Berger (1985), Berlioz (1938), Bertelli *et al.* (1997), Best & Clarke (1991), Bloch *et al.* (1991), Bond & Meyer de Schauensee (1943), Brown & Bowers (1985), Canevari *et al.* (1991), Colwell (1973), Colwell *et al.* (1974), Des Granges & Grant (1980), Dickey & van Rossem (1938), Elgar (1979, 1982a), Feinsinger (1976, 1977, 1980), Feinsinger & Colwell (1978), Fjeldså & Krabbe (1990), Friedmann *et al.* (1950), Gaunt *et al.* (1994), Hilty & Brown (1986), Howell & Webb (1995a), Johnsgard (1997), Lara & Ornelas (1998), Lyster *et al.* (1950), Lyon (1976), Martínez (1989), Meyer de Schauensee & Phelps (1978), Monroe (1968), Moynihan (1979), Olivares (1971), Olrog (1963b), de la Peña (1994), Phelps & Phelps (1958, 1965), Remsen (1985), Remsen, Traylor & Parkes (1986), Ridgely & Gwynne (1989), Ridgway (1911), Salaman & Mazariegos (1998b), Skutch (1967), Slud (1964), Snow & Snow (1980), Stiles (1985b), Stiles & Skutch (1989), Stotz *et al.* (1996), Wagner (1942, 1945, 1957b), Wetmore (1968a), Wolf & Stiles (1970), Wolf *et al.* (1976), Zimmer (1950d).

55. Sparkling Violet-ear

Colibri coruscans

French: Colibri anais German: Großer Veichenohrkolibri Spanish: Colibrí Rutilante
Other common names: Colombian/Gould's/Chequered Violet-ear

Taxonomy. *Trochilus (Petasophora) coruscans* Gould, 1846, South America.

Proposed race *rostratus* (mountains of upper Orinoco Valley) doubtfully distinct from *germanus*; only differences appear to be longer bill and tail. Form "*buckleyi*", known only by type from Bolivia, appears to refer to an aberrant plumage of present species, perhaps the poorly known melanistic form; a reported second specimen from Ecuador may refer to some different form. Two subspecies currently recognized.

Subspecies and Distribution.

- C. c. germanus* (Salvin & Godman, 1884) - S Venezuela, E Guyana and N Brazil.
- C. c. coruscans* (Gould, 1846) - NW Venezuela and Colombia through Ecuador and Peru to Bolivia and NW Argentina; possibly also N Chile.

Descriptive notes. 13-14 cm; male 7-7.8 g, female 6-7.7 g. Male has slightly decurved black bill; upperparts metallic bluish green, bluish violet ear plumes elongated and erect; chin bluish violet, rest of underparts green with blue belly; tail double-lobed, metallic green with steely blue subterminal band. A poorly understood melanistic form exists, but is rare (only 2 amongst over 300 specimens checked). Female similar to male, often has white postocular spot, smaller. Immature has no iridescent coloration, feathers fringed buff. Race *germanus* has forecrown, underparts and tail bluer.

Habitat. Forest edges, open woodland, flowering gardens, plantation, sub-páramo and páramo, at 1700-4500 m.

Food and Feeding. Feeds on nectar of a great variety of flowers like *Castilleja*, *Centropogon*, *Clusia*, *Echeveria*, *Elleanthus*, *Erythrina*, *Eucalyptus*, *Guzmania*, *Inga*, *Salvia*, *Siphocampylus* and *Puya*. Insects are caught in the air by hawking. Forages from ground level to canopy. Territorial, dominates all other hummingbirds at flowering trees; in páramo no aggressive interaction with other hummingbirds observed.

Breeding. Jul-Oct (Venezuela). Cup-shaped nest built of various soft plant materials, decorated outside with lichens and twigs; placed on horizontal branch or attached to pendent twig in bush or placed in cleft in rocks. Incubation 17-18 days, by female; chick dark with two rows of rufous dorsal down; fledging period 20-22 days. Records of males participating in raising young unlikely and need verification. At high altitudes hardly any nestling mortality due to predation.

On following pages: 56. White-vented Violet-ear (*Colibri serrirostris*); 57. Green-throated Mango (*Anthracothorax viridigula*); 58. Green-breasted Mango (*Anthracothorax prevostii*); 59. Black-throated Mango (*Anthracothorax nigricollis*); 60. Veraguas Mango (*Anthracothorax veraguensis*); 61. Antillean Mango (*Anthracothorax dominicus*); 62. Green Mango (*Anthracothorax viridis*); 63. Jamaican Mango (*Anthracothorax mango*); 64. Fiery-tailed Awi-bill (*Anthracothorax recurvirostris*).

Movements. During dry season populations in *páramo* habitats migrate to lower elevation; during this period recorded at altitudes of about 200 m. Populations at lower elevation present all year round, though some may show some seasonal dispersal. Recent record from N Chile (Andes of Tarapacá) in Jul may refer to vagrant, migrant or perhaps a hitherto unknown breeding population.

Status and Conservation. Not globally threatened. CITES II. Common in various habitat types including man-made flowering gardens and plantations, and can be observed in gardens of major cities like Bogotá, Quito and Cuzco. During recent decades has been imported for wild-bird trade into Europe.

56. White-vented Violet-ear

Colibri serrirostris

French: Colibri à ventre blanc **German:** Amethystohrkolibri **Spanish:** Colibrí Orejmorado
Other common names: Brazilian Violet-ear, Singing Hummingbird

Taxonomy. *Trochilus serrirostris* Vieillot, 1816, Brazil. Monotypic.

Distribution. Bolivia and C Paraguay to S Brazil (from Mato Grosso, Goiás, Bahia and Espírito Santo) and N Argentina (S to Córdoba).

Descriptive notes. 12-13 cm; 5.6-6.8 g. A medium-sized, shining green hummingbird with long, slightly decurved bill; male is lighter green than both *C. coruscans* and *C. thalassinus* with slight differences in coloration of subocular patch and ear-tufts; lower upperparts yellow-green with a blue shimmer; ear-coverts, subocular and postauricular regions spotted violet blue and can be mistaken for a collar. Rectrices glittering green with broad steel-blue subterminal band; undertail-coverts pure white. The upper mandible is sometimes serrated, and bill is same length as head. Female similar to male but slightly smaller, paler and more greyish green. Immature much like female but greyer underneath and greenish brown above, with whitish belly, white malar stripe and white outer corners to tail.

Habitat. Semi-open terrain of several types including scrub, savanna, grassland and bushy gorges. Occasionally in sparse forest. Perches in shrubs and small trees near dense flower patches. Ranges from sea-level (coastal Brazil) to as high as 3600 m (though rarely) in the Andes. Commonest in upland habitat at 1000-1500 m.

Food and Feeding. Very aggressive and territorial, commonly chasing competitors from flower patches. Frequently observed hawking for insects. Dominant birds stay on a nearby perch and call regularly when not feeding at flowers. Usually begins feeding early in the morning compared with other hummingbirds.

Breeding. Dec-Apr. All nest-building, incubation and care of young performed by female. External nest walls decorated with colourful lichens. Clutch 2; incubation 15 days; fledging 22-25 days.

Movements. Some populations make short migrations; birds at higher altitudes in Brazil (above tree-line) migrate to lowland regions in autumn.

Status and Conservation. Not globally threatened. CITES II. Common throughout much of range, particularly at medium altitudes; readily accepts man-made habitats, e.g. gardens and parks. In Brazil, frequently recorded in Itatiaia, Serra da Canastra, Serra do Cipó and Brasília National Parks. Recorded density of at least 1-2 pairs/km² in vicinity of São Paulo.

Bibliography. Alves & Cavalcanti (1996), Antas & Cavalcanti (1988), Belton (1984), Berry (1989), Bond & Meyer de Schauensee (1943), Canevari *et al.* (1991), Davis (1993), Dubs (1992), Elgar (1982a), Fjeldså & Krabbe (1990), Fjeldså & Mayer (1996), Forrester (1993), Grantsau (1988), Hayes (1995), Laubmann (1933, 1940), Oniki (1996), Papi & Ioale (1987), Park & Atyeo (1974), de la Peña (1994), Perry *et al.* (1997), Piratelli (1997), Remsen & Traylor (1989), do Rosário (1996), Ruschi (1949b, 1981-1982, 1982a, 1986), Sargeant (1996), Sazima (1977), Sazima & Sazima (1990), Short (1975), Sick (1993, 1997), Stotz *et al.* (1996), Tobias *et al.* (1993).

Genus ANTHRACOTHORAX Boie, 1831

57. Green-throated Mango

Anthracothorax viridigula

French: Mango à cravate verte **Spanish:** Mango Gorgiverde
German: Smaragdehl-Mangokolibri
Other common names: Green-throated/Black-breasted Hummingbird

Taxonomy. *Trochilus viridigula* Boddaert, 1783, Cayenne.

Probably belongs to the superspecies formed by *A. prevostii*, *A. nigricollis* and *A. veraguensis*. Monotypic.

Distribution. Trinidad, NE Venezuela and the Guianas to N Brazil (Amapá, N Pará, N Maranhão).
Descriptive notes. 10.5-12.5 cm; male 7.5-8.5 g, female 6.0 g; records of 11 g for female are possibly of egg-laying individuals. Male has slightly decurved black bill; upperparts shining bronzy-

green; throat glittering green, centre of breast and belly velvet black, sides green to bronzy-green, thighs and lower sides of body white; central tail feathers dark brown to green, with others shiny purple, outermost ones tipped dark blue. Female bill like male; upperparts similar to male; underparts mostly white with velvet black stripe from chin to belly; tail similar to male's but tipped white. Immature similar to female but sides of chin and underparts chestnut.

Habitat. Coastal regions, including mangrove, marshy savanna and similar open swamp-like habitats with scattered large trees. Forages

mainly in tree tops. Recorded between sea-level and 500 m.

Food and Feeding. Nectar of flowering native and introduced trees, e.g. *Erythrina*, *Caesalpinia*, *Tabebuia*, *Cordia*, *Spathodea*. Insects such as Hymenoptera, Hemiptera, Homoptera and Coleoptera are caught in the air or picked from plant surface. Male establishes feeding territories in flowering trees.

Breeding. Nests found all year round but chiefly Jan-Mar (Guianas). Small cup-shaped nest built on horizontal branch in large tree, normally above 10 m. Clutch size 2; incubation 15 days, by female; chick black with sparse, dark grey dorsal down; fledging period 24-25 days; young remain with adult female for 3-4 weeks. First breeding in second year.

Movements. Sedentary along coastal areas; follows flowering seasons of trees inland.

Status and Conservation. Not globally threatened. CITES II. Locally common, particularly in mangrove swamps and marshy coastal areas; less numerous inland. Has become a rather rare resident on Trinidad due to the loss of mangrove and swamp since the early 1980's; present at Caroni Swamp. Regularly recorded at Cayenne and Mana (French Guiana).

Bibliography. Bangs & Penard (1918), Chubb (1916), French (1991), Grantsau (1988), Haverschmidt & Mees (1994), Herklots (1961), Meyer de Schauensee (1982), Meyer de Schauensee & Phelps (1978), Olrog (1968), Ruschi (1953a, 1981-1982, 1986), Sick (1993, 1997), Snyder (1966), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Street (1946), Tostain *et al.* (1992).

58. Green-breasted Mango

Anthracothorax prevostii

French: Mango de Prévost **German:** Grünbrust-Mangokolibri **Spanish:** Mango Pechiverde
Other common names: Green-breasted Hummingbird; Prévost's Mango (*prevostii*); Ecuadorian Mango (*iridescens*)

Taxonomy. *Trochilus prevostii* Lesson, 1832, Veracruz, Mexico.

Forms superspecies with *A. nigricollis* and *A. veraguensis*, and probably also *A. viridigula*. Very closely related to *A. nigricollis*, and occasionally regarded as conspecific, the two evidently replacing each other geographically, with at most very local sympatry in N Venezuela, SW Colombia and perhaps elsewhere. Often considered conspecific with *A. veraguensis*. Race *iridescens* has alternatively been treated as a race of *A. nigricollis*, or a full species. Proposed race *nigrilineatus* of Bay Is (Honduras) now held to be inseparable from *gracilirostris*; proposed *pinchoiti* of San Andrés I generally regarded as inseparable from *hendersoni*. Five subspecies currently recognized.

Subspecies and Distribution.

A. p. prevostii (Lesson, 1832) - E & S Mexico S to Guatemala, Belize and (possibly migrants) El Salvador.

A. p. gracilirostris Ridgway, 1910 - El Salvador and Honduras S to C Costa Rica.

A. p. hendersoni (Cory, 1887) - San Andrés I and Providencia I in W Caribbean.

A. p. viridicordatus Cory, 1913 - extreme NE Colombia (Guajira Peninsula) and coastal slope of N Venezuela.

A. p. iridescens (Gould, 1861) - arid upper Cauca Valley (W Colombia), and coastal slope of SW Ecuador and extreme NW Peru.

Descriptive notes. 11-12 cm; male 7.2 g, female 6.8 g (*gracilirostris*). Male bronzy-green above, bright green below, centre of throat and breast extensively black, bordered laterally with deep blue; outer four rectrices purple, narrowly edged with black. Female mostly white below with green sides and a broad central stripe of black mixed with green, outer four rectrices with subterminal black-band and narrow white tip; plumage of a small proportion of adult females like that of adult male and apparently requires two or more years to attain. Young bird has dark central stripe bordered or smudged with rufous (including *iridescens*, and unlike *A. nigricollis*) and buffy fringes over much of back. Race *gracilirostris* has shorter, more slender bill than nominate and upperparts less golden green; *viridicordatus* has upperparts grass green, undertail-coverts darker, central rectrices more olive-green; *hendersoni* is more bronzy-green above and black throat-stripe of male much less conspicuous; most distinct is *iridescens*, in which the black of the throat and chest of the male is much more extensive, approaching *A. nigricollis*, but female resembles that of *prevostii* in having central black stripe mixed with green and greater extent of white on lower face.

Habitat. Open grassy or shrubby areas with scattered taller trees, especially near water; savannas, pastures, parks, gardens, shaded coffee plantations, also borders of gallery woodland and mangroves, tall second growth. Mostly lowlands, locally to 900-1200 m.

Food and Feeding. Visits mostly flowers of trees (*Inga*, *Caesalpinia*, *Bauhinia*, *Erythrina*, *Ceiba*, *Calycophyllum*), vines and lianas (*Combretum*, *Ipomoea*) and shrubs (*Hibiscus*, *Quassia*), usually well above ground; several may gather at a large flowering tree where aggressive males sometimes defend feeding territories. Frequently flycatches high in the air, sallying from perch or during prolonged bouts of hovering and darting; also gleans arthropods from foliage, spiderwebs, or window screens.

Breeding. Mainly during dry season, Dec-May in Costa Rica, Oct and Feb-Mar in El Salvador, Mar in N Colombia. During breeding season male sings a buzzy, twangy song of short phrases rapidly repeated 3-4 times per bout, from song perches high in isolated trees, or in flight between perches. Nest a shallow cup of light-coloured plant down and cobweb, decorated sparsely or not at

all with bits of bark or lichen, situated on high outer twig of leafless or sparsely-foliaged tree, 15-25 m above ground. Clutch size 2. No further information.

Movements. Ranges rather widely following changes in flowering on a local basis, but no long-distance migration known. Nominate strays to extreme S USA.

Status and Conservation. Not globally threatened. CITES II. Uncommon to very common in different parts of range, and in many areas expanding range with deforestation; readily accepts man-made habitats, e.g. city parks and gardens with scattered fruit trees. Occurs in Santa Rosa and Palo Verde National Parks (Costa Rica); also regularly recorded at Tecolutla, Sierra de Los Tuxtlas, Tuxtpec, Yaxchilán and Uxmal (Mexico).

Bibliography. Bond (1950, 1985), Butler (1979), DeBenedictis (1994), Dickey & van Rossem (1938), Fogden (1993), Friedmann *et al.* (1950), Hilty & Brown (1986), Howell, S.N.G. & Webb (1995a), Howell, T.R. (1957), Johnsgard (1997), Land (1970), Lowery & Dalquest (1951), Meyer de Schauensee & Phelps (1978), Monroe (1968), Parker *et al.* (1982), Raffaele *et al.* (1998), Ridgely & Gwynne (1989), Ridgway (1911), Russell (1964), Russell *et al.* (1979), Slud (1964, 1980), Smith (1966), Stiles (1985c), Stiles & Skutch (1989), Stotz *et al.* (1996), Wagner (1946a), Warner & Mengel (1951), Wolf (1970), Zimmer (1950d).

59. Black-throated Mango

Anthracothorax nigricollis

French: Mango à cravate noire

German: Schwarzbrust-Mangokolibri

Spanish: Mango Gorginegro

Taxonomy. *Trochilus nigricollis* Vieillot, 1817, Brazil.

Forms superspecies with *A. prevostii* and *A. veraguensis*, and probably also *A. viridigula*. Very closely related to *A. prevostii*, and occasionally regarded as conspecific, the two evidently replacing each other geographically, with at most very local sympatry in N Venezuela. SW Colombia and perhaps elsewhere; *A. p. iridescens* has alternatively been attributed to present species. Monotypic.

Distribution. W Panama and Colombia E to Trinidad and Tobago and the Guianas, and S to Peru, E Bolivia, Paraguay, NE Argentina and S Brazil.

Descriptive notes. 11-12 cm; male 6-9 g, female 7-3 g. Male has slightly decurved black bill; upperparts bronzy-green; underparts, centre of breast and abdomen velvet black bordered with iridescent blue-green; tail mainly deep chestnut, glossed purple, edged dark blue. Female bill similar to male; upperparts as male; on underparts, central stripe from chin to abdomen velvet black, broadly bordered white on both sides; tail as in male but with broad blackish subterminal band, tipped white. Immature like adult female with feathers on head and lower back edged brown.

Habitat. Open garden-like vegetation with bushes and scattered trees; cultivated slopes of mountain ranges. Normally confined to tropical areas up to 1000 m.

Food and Feeding. Nectar of mainly tall flowering trees (*Erythrina*, *Tabebuia*, *Spathodea*), also feeds at vines and shrubs (*Russelia*, *Ixora*, *Hibiscus*). Hawks for insects in the open, often high above tree tops or among foliage. Male occupies feeding territories in flowering trees.

Breeding. Dec-Jul. Small cup-shaped nest made of fine, whitish plant material decorated with lichen, usually saddled on horizontal branch and rather exposed, normally at 8-15 m, rarely lower. Clutch size 2; incubation period 16-18 days, by female; young blackish, 2 rows of greyish natal down; fledging period 20-24 days, young remaining with female for 3-4 weeks; 2 broods. First breeding in second year.

Movements. Migration to higher altitudes in Aug-Sept; long-distance migration reported from E Brazil.

Status and Conservation. Not globally threatened. CITES II. Common in cultivated areas; also commonly seen in parks of big cities, e.g. Asunción (Paraguay) and Caracas (Venezuela); one of the most easily seen hummingbirds in many areas. Densities on Trinidad (Arima Valley) at least 8-12 birds/km², in Colombia (Valle del Cauca) at least 6-8 birds/km².

Bibliography. Belton (1984), Bertonatti & Heinonen (1988), Berton (1930), Bond & Meyer de Schauensee (1943), Borrero (1972), Broom (1976), Canevari *et al.* (1991), Contreras (1992), Contreras *et al.* (1990), Cotton (1998a), Feinsinger (1980), ffrrench (1991), Fisher & Wetmore (1931), Fritsch & Schuchmann (1988), Grantsau (1988), Gyldestolpe (1945b), Hartman & Lessler (1963), Haverschmidt & Mees (1994), Hayes (1995), Hayes & Samad (1998), Hellmayr (1929), Herklotz (1961), Herrera (1998), Hilty & Brown (1986), Krüger *et al.* (1982), Labude (1986), Meyer de Schauensee & Phelps (1978), Munves (1975), Navas & Bo (1993), Olivares (1963), Olivares & Hernández (1962), Oniki (1996), de la Peña (1994), Pereyra (1950), Pople *et al.* (1997), Quesnel (1995), Ridgely & Gwynne (1989), do Rosário (1996), Ruschi (1957b, 1967d, 1973d, 1981-1982, 1982a, 1986), Rutgers & Norris (1972), Saibene *et al.* (1996), Schuchmann & Prinzing (1987), Short (1975), Sick (1993, 1997), Snow, B.K. & Snow (1972), Snow, D.W. & Snow (1980), Steinbacher (1962), Stotz *et al.* (1996), Street (1946), Tostain *et al.* (1992), Voous (1983), Wetmore (1939, 1968a), Willis & Eisenmann (1979), Zimmer (1950d).

60. Veraguas Mango

Anthracothorax veraguensis

French: Mango de Veragua

German: Veragua-Mangokolibri

Spanish: Mango de Veragua

Taxonomy. *Anthracothorax veraguensis* Reichenbach, 1855, Veragua, Panama.

Forms superspecies with *A. prevostii* and *A. nigricollis*, and probably also *A. viridigula*. Often considered a race of *A. prevostii*. Monotypic.

Distribution. Panama, in Pacific lowlands from Chiriquí to S Cocle; two records from Caribbean side of Canal Zone (Gatún).

Descriptive notes. 11-12 cm; 7-0 g. Male has slightly decurved black bill; upperparts metallic bronzy-green; underparts shiny green, bluish on breast and centre of belly; tail mostly maroon, tipped black. Female bill similar to male; upperparts metallic green; underparts white from chin to lower abdomen with broad central stripe of greenish blue; tail blackish, outer rectrices tipped white. Immature like female, but with rufous-bordered central stripe.

Habitat. Open vegetation of pastures and stream edges with shrubs and scattered trees.

Food and Feeding. Nectar of flowering shrubs such as *Calliandra*, and trees such as *Erythrina* and *Inga*, from near ground to 10 m. Territorial at mass-flowering trees.

Breeding. No information.

Movements. Apparently sedentary, little information available.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species; present in South Central American Pacific Slope EBA. Locally common. A poorly studied species; extensive research required.

Bibliography. Anon. (1998a), Olson (1993), Ridgely & Gwynne (1989), Wetmore (1968a).

61. Antillean Mango

Anthracothorax dominicus

French: Mango doré

German: Dominikanermangokolibri

Spanish: Mango Antillano

Other common names: Puerto Rican Golden Hummingbird

Taxonomy. *Trochilus dominicus* Linnaeus, 1766, Hispaniola.

Appears to be closely related to *A. mango*. Two subspecies recognized.

Subspecies and Distribution.

A. d. dominicus (Linnaeus, 1766) - Hispaniola and offshore islands of Tortue, Gonâve, Vache and Beata.

A. d. aurulentus (Audebert & Vieillot, 1801) - Puerto Rico and offshore islands of Culebra and Vieques, and Virgin Is (St Thomas, St John, Anegada).

Descriptive notes. 11-12.5 cm; male 6-8 g, female 4-7 g. Male has slightly curved black bill; upperparts shiny green-bronze; chin and throat metallic green, rest of underparts velvet black; tail violet with blue-black tips. Female bill similar to male's; upperparts shiny green-bronze; small white spot behind eye; underparts grey, pale white on abdomen. Immature similar to adult female with velvet black median line, no white spot behind eye. Male *aurulentus* smaller than nominate, with gorget brighter, less black below; female with outer tail feathers basally brownish grey, not violaceous chestnut as in nominate.

Habitat. Clearings, gardens, secondary growth and arid shrubby hillsides along the coast, rare above 800 m and inside forests.

Food and Feeding. Nectar of flowering *Cordia*, *Melocactus*, *Bauhinia*, *Ipomea*, *Hibiscus*, *Erythrina*, *Sabineia*, etc. Insects are caught in the air, spiders collected from the surface of leaves and bark. Forages from lower mid-strata to tree tops. Male defends nectar-rich territories.

Breeding. Mar-Nov. Compact cup-shaped nest, lined with soft plant fibre, often coated with lichen, built mainly in tree at 3-12 m. Clutch size 2; chick black with two rows of greyish dorsal down; single brood. No further information available.

Movements. Sedentary.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species; present in Hispaniola EBA and Puerto Rico and the Virgin Islands EBA. Generally common in coastal areas with scattered trees. Probably extinct now on St John and Anegada (Virgin Is) and perhaps also on Vieques, while rare on E Puerto Rico, apparently all as a result of competition from *Eulampis holosericeus*.

Bibliography. Anon. (1998a), Biaggi (1983), Bond (1985), Dod (1987, 1992), Kodric-Brown *et al.* (1984), Otero (1998), Raffaele (1989), Raffaele *et al.* (1998), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Tyrrell & Tyrrell (1990), Wetmore (1927), Wetmore & Swales (1931).

62. Green Mango

Anthracothorax viridis

French: Mango vert

German: Smaragd mangokolibri

Spanish: Mango Portorriqueño

Other common names: Puerto Rican Mango

Taxonomy. *Trochilus viridis* Audebert and Vieillot, 1801, Puerto Rico.

Monotypic.

Distribution. Puerto Rico.

Descriptive notes. 11-14 cm; 7 g. Sexes alike. Bill slightly curved, black; upperparts emerald green; underparts metallic blue-green; tail metallic blue-black, rounded. Adult female with tiny white eye-spot, lacking in male. Immature with brownish-tinged feathers on head and back.

Habitat. Plantations and forests of C and W mountains. Rare in coastal areas. Most common between 800 and 1200 m.

Food and Feeding. Nectar of flowering trees, shrubs and vines, such as *Pariti tilaceum*, *Leonotis leonotum*, *Quisqualis indica* and *Ipomea* sp. Insects are caught in the air, often above tree tops. Spiders collected from the surface of leaves are another important protein source.

Indigestible chitinous food remains are regurgitated as pellets. Forages from low understorey to tree-top levels. Male defends territories at flowering trees.

Breeding. Nest records Oct-May. The nest is a soft, compact cup decorated externally with lichen; attached to vertical branch of high tree, normally above 8 m. Clutch size 2; chick black with 2 rows of dorsal down; single brood. No further information available.

Movements. Altitudinal movements depending on flowering seasons.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species; present in Puerto Rico and the Virgin Islands EBA. Common resident in the C and W mountains of Puerto Rico. Readily accepts man-made habitats like coffee plantations.

Bibliography. Anon. (1998a), Biaggi (1983), Bond (1985), Kodric-Brown *et al.* (1984), Ornelas (1994), Raffaele (1989), Raffaele *et al.* (1998), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Tyrrell & Tyrrell (1990), Wetmore (1927).

63. Jamaican Mango

Anthracothorax mango

French: Mango de la Jamaïque **German:** Jamaikamangokolibri **Spanish:** Mango Jamaicano
Other common names: Black Mango

Taxonomy. *Trochilus Mango* Linnaeus, 1758, Jamaica.

Appears to be closely related to *A. dominicus*; closest Central American relative is probably *A. prevostii*. Monotypic.

Distribution. Jamaica.

Descriptive notes. 11-12 cm; 8-5 g. Medium-sized darkish hummingbird easily distinguishable from all other *Anthracothorax* species. Male has bill slightly curved, black; crown faded green, sides of head and neck metallic magenta purple; below velvet black, back dull green-bronze; central tail feathers dusky bronze to dull black, rest metallic violet with narrow dark blue band. Female similar to male; faded green velvet on flanks; outer tail feathers tipped white. Immature male with deep blue throat becoming velvety after the second year.

Habitat. Wide range of open and semi-open lowland vegetation including arid areas, gardens and plantations. Common along forest edges from sea-level to 800 m. Regular but rare, except for Jun-Aug., at natural edges of wet mid-altitude and elfin forest at 900-1500 m; scarce in mangroves.

Food and Feeding. Nectar from a wide variety of bird-adapted flowers of indigenous and introduced plants: *Hohenbergia*, *Opuntia*, *Stenocereus*, *Cordia*, *Tabebuia*, *Spathodea*, *Bauhinia*. Males are territorial at mass-flowering trees. Small arthropods caught on the wing in open space, often at 10-15 m.

Breeding. Nests all year round, most frequently during Jan-May. Small cup-shaped nest of densely woven silky fibres and cobwebs saddled on thick branch of tree at 3-8 m. Clutch size 2; incubation by female; chick blackish, 2 rows of greyish dorsal down; single brood. No further information.

Movements. Birds disperse to mid-altitude regions (Cockpit Country) and to Blue and John Crow Mts in Jun-Aug, following the flowering season at higher altitudes.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species; present in Jamaica EBA. Common resident. Particularly common along northern coastal areas with densities of at least 5-8 individuals/km². Ready occupation of man-made habitats suggests that habitat loss is unlikely to be a problem.

Bibliography. Anon. (1998a), Bond (1985), Danforth (1928), Downer & Sutton (1990), Lack (1976), Pearson (1980), Raffaele *et al.* (1998), Salmon (1972), Stattersfield *et al.* (1998), Stoltz *et al.* (1996), Schuchmann (1980a, 1980b, 1980c, 1990a), Tyrrell & Tyrrell (1990).

64. Fiery-tailed Aowlbill

Anthracothorax recurvirostris

French: Colibri avocette **German:** Schwarzbauch-Avosettkolibri **Spanish:** Mango Picolezn
Other common names: Swainson's Hummingbird, Fiery-tailed Avocetbill

Taxonomy. *Trochilus recurvirostris* Swainson, 1822, Peru; error = Cayenne.

Normally placed in monospecific genus *Avocettula*, mainly due to remarkable form of bill; other details of morphology, however, together with behaviour and nest structure, support positioning within *Anthracothorax*. Monotypic.

Distribution. SE Venezuela (Bolívar) and the Guianas to NC Brazil (lower Amazon E to Maranhão and Piauí); E Ecuador (Napo Valley).

Descriptive notes. 8-10 cm; 4-3 g. Male has short bill, strongly upturned at tip, black; back green; throat and breast glittering emerald, centre of belly black, sides dull green; tail violet above, central feathers green. Female similar to male, underparts white with central black stripe, sides copper-green; tail shows more blue-black, and outer feathers tipped white. Immature like adult female with tail coppery red underneath.

Habitat. Occurs in open savanna-like vegetation near granite outcrops within primary forest from sea-level to 500 m, occasionally at edges of low secondary vegetation near rivers.

Most numerous around 100-200 m. Foraging height around 1-3 m.

Food and Feeding. Collects nectar at the periphery of flowering *Clusia* and *Dioclea* shrubs. Hawks for insects in the air or gleans them from the underside of leaves. Feeds mainly by trap-lining.

Breeding. Sept-Dec in Surinam, records from Jul for French Guiana and N Brazil. Cup-shaped nest very small, saddled on thick horizontal branch of tall shrub or tree at 5-12 m. Clutch size 2; incubation by female; young black with sparse whitish dorsal down. No further information available.

Movements. Presumably sedentary.

Status and Conservation. Not globally threatened. CITES II. Currently considered Near-threatened. Widespread but generally considered rare; restricted to small areas of suitable habitat, particularly inselbergs. In the Voltzberg area of Surinam density of at least 2 individuals/km² recorded.

Bibliography. Bené (1947), Berlepsch (1908), Best *et al.* (1997), Butler (1979), Grantsau (1988), Haverschmidt & Mees (1994), Ingels (1981), Meyer de Schauensee & Phelps (1978), Ruschi (1981-1982, 1986), Schuchmann-Wegert & Schuchmann (1984), Sick (1993, 1997), Snyder (1966), Stoltz, Fitzpatrick *et al.* (1996), Stoltz, Lanyon *et al.* (1997), Tostain *et al.* (1992), Trail (1978).

PLATE 50

inches 2
cm 5

Genus *TOPAZA* G. R. Gray, 1840

65. Crimson Topaz

Topaza pella

French: Colibri topaze **German:** Rotnacken-Topaskolibri **Spanish:** Colibrí Topacio
Other common names: Topaz/Topaz-throated/King Hummingbird, Beautiful Topaz; Fiery/Inca Topaz (*pyra*)

Taxonomy. *Trochilus Pella* Linnaeus, 1758, Surinam.
Genus probably related to *Eulampis* and *Anthracothorax*, on basis of form of nest and display; has traditionally been placed close to *Oreotrochilus*. Race *pyra* often considered a separate species, but size and colour patterns indicate geographical variation only at subspecies level; some individuals of nominate race show glittering orange belly, thus resembling *pyra*. Race *smaregdula* has been proposed for birds of French Guiana, but not separable from nominate. Four subspecies currently recognized.

Subspecies and Distribution.

T. p. pyra (Gould, 1846) - SE Colombia, E Ecuador and NE Peru to NW Brazil (R Negro) and S Venezuela (Amazonas).

T. p. pamprepta Oberholser, 1902 - E Ecuador (Suno, R Napo).

T. p. pella (Linnaeus, 1758) - S Venezuela (E Bolívar) and the Guianas to N Brazil (Amapá).

T. p. microrhyncha Butler, 1926 - NC Brazil, along S bank of lower Amazon in vicinity of Belém.

Descriptive notes. Male 21-23 cm (including bill 4.3 cm and tail 12-13 cm), 10-14 g; female 13-14 cm, 10 g. A large, strikingly coloured species. Male has straight black bill; top and sides of head and neck velvet black; back glittering crimson to purple, golden on uppertail-coverts; throat bright green with a golden sheen, surrounded by a black band, underparts bright red, undertail-coverts bronze; wings brown; central tail feathers bronzy golden-green, outer tail feathers chestnut, submedian tail feathers elongated and crossed. Female bill similar to male's; back dark green; throat green with crimson discs, underparts green with

golden green discs, undertail-coverts shining green; central tail feathers bronzy, next pair violet, outermost pair chestnut. Immature like female. Male of *pyra* is glittering orange-red on underparts; tail bronze-green in centre, remainder blackish violet; female similar to nominate *pella* but tail blackish violet, only outer tail feathers with cinnamon outer web. Race *pamprepta* differs in shorter wing and longer tail; *microrhyncha*, the smallest of all races, with smaller bill, tends to have more reddish tone on throat patch, though this appears to vary clineally. Melanistic and albinotic individuals of the nominate race are relatively common.

Habitat. Occurs in lowland rainforests up to 500 m, mainly inland. Frequently found in tree tops of forests around granite outcrops and along gallery forests near river banks and creeks.

Food and Feeding. Mainly seen foraging for nectar in the upper storey of flowering forest trees such as *Inga* and *Bombax*, but also visits flowers of vines and epiphytes, e.g. Bromeliaceae, Gesneriaceae, Ericaceae. Occasionally found in much lower vegetation around inselbergs in Surinam where it forages for nectar near the ground at flowering stands of *Costus scaber* and in clumps of blooming *Pitcairnia nuda*. Male establishes feeding territories. Insects are caught in the air, often high above tree tops.

Breeding. Jan-Apr and again in Jul-Nov in the Guianas; no nesting data from other areas. Nests found at 3-8 m, often on vertical branches or in vines above or near water. The cup-shaped nest, consisting of soft greyish or brownish fibres of *Bombax* seeds and cobweb, is fairly small compared with the size of the bird. Clutch size 2; incubation by female, time unknown; chick black with some pale grey dorsal down; fledging period 21 days; young remain with female for 3 weeks. First breeding in the second year.

Movements. Mainly sedentary during the reproductive periods, thereafter number of individuals may decrease locally, probably following flowering season elsewhere.

Status and Conservation. Not globally threatened. CITES II. Locally common but frequently considered rare due to its secretive habits in the tree tops. In Guyana (Demerara River) more than 10 individuals/km² have been reported, and at least 8-12 individuals/km² near Voltzberg Nature Reserve in Surinam. No abundance data available for Amazonia and the western range of the species. Appears to have declined following extensive logging in E Ecuador (R Napo); race *pamprepta* has not been recorded in the Río Napo area for decades. Present in Imataca Forest Reserve (Venezuela), also (*pyra*) in Cuyabeno National Park (Ecuador).

Bibliography. Berlioz (1964), Blake (1950b), Butler (1979), Davis (1958), Grantsau (1988), Haverschmidt & Mees (1994), Hilty & Brown (1986), Ingels (1981), Meyer de Schauensee & Phelps (1978), Nicholson (1931), Norton (1965), Parker *et al.* (1982), Penard & Penard (1910), Peres & Whittaker (1991), Ruschi (1973d, 1977, 1981-1982, 1982a, 1986), Rutgers & Norris (1972), Schuchmann (1982a), Sick (1993, 1997), Snyder (1966), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Tostain *et al.* (1992), Willard *et al.* (1991), Zimmer (1951a).

Genus *EULAMPIS* Boie, 1831

66. Purple-throated Carib

Eulampis jugularis

French: Colibri madère **German:** Purpurkehlkolibri **Spanish:** Colibrí Caribeño Gorgimorado
Other common names: Purple/Purple-breasted Carib, Garnet/Red-breasted Hummingbird

Taxonomy. *Trochilus jugularis* Linnaeus, 1766, Cayenne and Surinam; error = Lesser Antilles.

Genus closely related to *Anthracothorax* and *Topaza*. Monotypic.

Distribution. Lesser Antilles, from Saba, St Eustatius, St Kitts, Nevis, Antigua and Montserrat through Guadeloupe, Dominica and Martinique to St Lucia and St Vincent.

Descriptive notes. 11-12 cm; male 9-12 g, female 7-10 g. Male has short bill, slightly curved, black. A sturdy, dark velvet hummingbird. Malar region, throat and chest fiery purplish red; undertail and uppertail-coverts metallic greenish blue; wings bright golden green. Female similar to male but bill longer and more decurved. Immature throat and chest orange with red speckles.

Habitat. Forest edges and tree tops of secondary and primary forest at altitudes of 800-1200 m.

Food and Feeding. Nectar of indigenous (*Cordia*, *Clusia*) and introduced trees (*Spathodea*, *Delonix*, *Caesalpinia*). Forages from mid-

strata to tree tops; occasionally visits flowering stands of *Heliconia caribaea* and banana (*Musa*) at heights of 2-3 m. Hawks for small insects on the wing, more frequently seen gleaning arthropods from leaves and spider webs. Male holds flower-centred territories all year round, female only during non-breeding season.

Breeding. Feb-May, occasionally Jan-Sept. Cup-shaped compact nest on vertical branch in tree at 3-5 m, rather small compared with the size of the bird. Nest material consists of soft plant fibres and spider web, occasionally camouflaged with thin strips of bark, moss or lichen on the outer nest wall. Clutch size 2; incubation 17-19 days, by female; chick darkish, two dorsal rows of down; fledging period 17-20 days; young remain with female for 2-3 weeks; single brood. Female very territorial around the nest, attacking even much larger species within 10 m of the nest.

Movements. On some islands (St Lucia, St Vincent) individuals occur at sea-level at end of May. Casual occurrence on Barbuda, Désirade, Is des Saintes and Bequia (Grenadines); sight records for Grenada and Barbados; rare straggler to the Greater Antilles.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species: present in Lesser Antilles EBA. Common resident in forests and plantations at higher altitudes. Density in the Edmond Forest Reserve on St Lucia at least 8-12 pairs/km². Ready occupation of man-made habitats suggests that habitat loss is unlikely to be a problem.

Bibliography. Anon. (1998a), Belton (1996), Bond (1985), Chávez-Ramírez & Dowd (1992), Chávez-Ramírez & Tan (1993), Hainsworth & Wolf (1970), Ingels (1976a, 1976b), Keith (1997), Krüger *et al.* (1982), Kunze (1984), Lack (1973), Leck (1973), Lodge (1896), Mobbs (1976), Norton & Hobbs (1987), Raffaele *et al.* (1998), Rutgers & Norris (1972), Schuchmann (1977b, 1978a, 1979f, 1980c, 1981), Schuchmann & Jakob (1981b), Schuchmann & Prininger (1987), Schuchmann & Schuchmann-Wegert (1984), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Tyrrell & Tyrrell (1990), Wolf (1975b, 1975c), Wolf & Wolf (1971), Zusi & Bentz (1984).

67. Green-throated Carib

Eulampis holosericeus

French: Colibri falle-vert **German:** Blaustern-Antillenkolibri **Spanish:** Colibrí Caribeño Gorgiverde
Other common names: Emerald-throated Carib/Hummingbird, Green Doctor Bird, Green Carib

Taxonomy. *Trochilus holosericeus* Linnaeus, 1758, Lesser Antilles.

Genus closely related to continental *Anthracothorax* and *Topaza*. Sometimes placed in monotypic genus *Sericotes*, on basis of more naked tarsi, rounded tail, and different coloration. Two subspecies recognized.

Subspecies and Distribution.

E. h. holosericeus (Linnaeus, 1758) - E Puerto Rico and Lesser Antilles (except Grenada).

E. h. chlorolaemus (Gould, 1857) - Grenada.

Descriptive notes. 11-12.5 cm; male 5.6-7.8 g, female 5.5-5.5 g. Male has medium-sized bill, slightly decurved, black. Upperparts metallic bronzy-green, uppertail-coverts blue-green; malar region, chin and throat metallic green, breast centre violet-blue, belly velvet black, undertail-coverts metallic blue; tail dark blue, rounded. Female similar to male, bill longer and more decurved. Immature like female, head feathers tinged brown. Race *chlorolaemus* differs from nominate by darker green throat and broad deep violet-blue patch on centre of breast.

Habitat. Open secondary vegetation, cultivated

areas, parks, semi-deciduous and rainforest at all elevations. More common from sea-level to 500 m.

Food and Feeding. Nectar of flowers of shrubs and small trees 1-4 m in height. Occasionally territorial at *Lantana* and *Bryophyllum* bushes. Forages for insects in the air, collects small spiders from webs.

Breeding. Feb-May. Compact cup-shaped nest is built at 1-4 m on the periphery of trees and bushes. Nest is placed in a saddle-like position on twigs, camouflaged outside by pieces of bark and lichen. Nest inside lined with soft fibres of seeds, cacti and tree ferns. Clutch size 2; incubation 17-19 days, by female; chick flesh-coloured, dorsally two rows of down; fledging period 20-22 days; young remain with female for 3-4 weeks; normally one brood. First breeding in second year.

Movements. Individuals disperse in Jun-Sept to forest borders at higher altitudes at c. 800-1000 m.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species: present in Puerto Rico and the Virgin Islands EBA and Lesser Antilles EBA. Common resident. Particularly numerous at sea-level on Basse Terre, Guadeloupe, with densities of at least 5-7 pairs/km². Ready occupation of man-made habitats suggests that habitat loss should pose no danger.

Bibliography. Anon. (1998a), Bond (1985), Bos (1989), Chávez-Ramírez & Dowd (1992), Chávez-Ramírez & Tan (1993), Ingels (1976a), Keith (1997), Lack (1973), Leck (1973), Moller (1930), Raffaele (1989), Raffaele *et al.* (1998), Rutgers & Norris (1972), Schuchmann (1979b, 1980c, 1981), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Tyrrell & Tyrrell (1990), Wolf (1975c).

Genus *CHRY SOLAMPIS* Boie, 1831

68. Ruby Topaz

Chrysolampis mosquitus

French: Colibri rubis-topaze

German: Moskitokolibri

Spanish: Colibrí Rubí

Other common names: Ruby-topaz Hummingbird

Taxonomy. *Trochilus Mosquitus* Linnaeus, 1758, Surinam.Closely related to *Orthorhynchus*, and may even be congeneric. Monotypic.**Distribution.** E Panama and W, N & C Colombia E through Venezuela to the Guianas, then S through NE & C Brazil (Pará to Pernambuco and S to Mato Grosso) to E Bolivia; also islands along N coast from Aruba, Curaçao and Bonaire E to Trinidad and Tobago.**Descriptive notes.** 8-9 cm; 4-5 g. Male has short straight black bill; crown and nape shining ruby red (occasionally orange), back dark brown glossed dull olive; throat and breast iridescent golden (occasionally emerald-green); rest of underparts brown; tail rich chestnut tipped black. Female has copper-green back; below pale grey (on both Trinidad and Tobago, some birds have greenish-golden stripe from chin to breast); central tail feathers olive-green, the others rufous-chestnut with shining purple-black subterminal band, tipped white. Immature similar to adult female; has white spot behind eye,

outer tail dark violet, tipped white.

Habitat. Occurs in savanna-like vegetation from sea-level to shrubby arid hillsides at 1700 m; forages from low down to treetops in clearings, open country, gardens and cultivated areas. Most numerous below 500 m; birds at higher altitudes are currently not breeding.**Food and Feeding.** Nectar of flowering shrubs, cultivated crops, cacti, small and large trees: *Russelia*, *Cajanus*, *Iseria*, *Melocactus*, *Citharexylum*, *Samanea*, *Cordia*. Small insects are caught in the air by hawking. Occasionally seen foraging for arthropods among foliage along clearings and roads. Male defends feeding territories in flowering shrubs or trees.**Breeding.** Dec-Jun on Trinidad and Tobago, Venezuela, Guianas; Sept-Jan in Brazil. Tiny cup-shaped nest of fine plant fibre and cobweb, outside decorated with lichen and/or pieces of bark, is built in fork of small branch, 1-4 m above ground, occasionally up to 8 m. Clutch size 2; incubation 15-16 days, by female; chick black with sparse brownish dorsal down; fledging in 19-22 days. First breeding in second year.**Movements.** Migratory. Arrives in the southern Cauca Valley, Colombia, in May and disappears in Sept; absent or rare on Trinidad and Tobago in Aug-Nov; appears in Paraná, Brazil, in Oct and leaves in Apr. Within Brazil, N-S migration; along the coastal areas of the Guianas, Venezuela and Colombia presumably an E-W migration with southward tendency towards Cauca and Magdalena Valleys, Colombia.**Status and Conservation.** Not globally threatened. CITES II. Common resident in the lowlands and coastal ranges, with densities of at least 6-8 pairs/km² in shrub-like habitats of SW Trinidad. Readily accepts man-made habitats like gardens and cultivated areas. Present in Tayrona National Park (Colombia). Until 1970 the most sought-after species of hummingbird for the international bird trade in Brazil; this has now been ended.**Bibliography.** Allen (1961), Bos (1989), Braun & Wolf (1987), Craigie (1928), Feinsinger (1980), French (1991), Friedmann & Smith (1950), Grantsau (1988), Haverschmidt & Mees (1994), Herklots (1961), Hilty & Brown (1986), Meyer de Schauensee & Phelps (1978), Mobbs (1969, 1977), Oniki (1996), Raw (1996), Remsen & Traylor (1989), Ridgely & Gwynne (1989), do Rosário (1996), Ruschi (1953b, 1962f, 1964d, 1967a, 1973d, 1981-1982, 1982a, 1986), Rutgers & Norris (1972), Salaman & Mazariegos (1998a), Sanft (1970), Schürer (1983), Sick (1993, 1997), Snow & Snow (1972), Snyder (1966), Stotz *et al.* (1996), Tostain *et al.* (1992), Voous (1983).Genus *ORTHORHYNCUS* Lacépède, 1799

69. Antillean Crested Hummingbird

Orthorhynchus cristatus

French: Colibri huppé

German: Antillenhaubenkolibri

Spanish: Colibrí Crestado

Other common names: Crested Hummingbird

Taxonomy. *Trochilus cristatus* Linnaeus, 1758, Barbados.Closely related to *Chrysolampis*, and may even be congeneric. Four subspecies recognized.**Subspecies and Distribution.***O. c. exilis* (J. F. Gmelin, 1788) - E Puerto Rico S through Lesser Antilles to St Lucia.*O. c. ornatus* Gould, 1861 - St Vincent.*O. c. cristatus* (Linnaeus, 1758) - Barbados.*O. c. emigrans* Lawrence, 1877 - Grenadines and Grenada.**Descriptive notes.** 8-9.5 cm; male 4 g, female 3-5 g. Male has short straight black bill; head with green crest, tipped metallic green to bright blue-green, upperparts dull metallic bronze-green; underparts sooty black; tail black, rounded. Female bill similar to male's; head without crest, forehead, crown and upperparts metallic bronzy-green; underparts light grey; tail blackish, rounded, four outer rectrices broadly tipped whitish grey. Immature like female, head feathers tinged cinnamon. Races distinguished by crest colour: *exilis* wholly green or slightly tinged blue on tip; *ornatus* terminal portion abruptly blue; *cristatus* golden to emerald, violet terminally; *emigrans* like nominate but more bluish violet, throat paler grey; degree of paleness in underparts of female varies with race.**Habitat.** Open vegetation, parks, plantations, forest borders from sea-level to high mountains. Commonest below 500 m.**Food and Feeding.** Nectar of flowering shrubs (*Lantana*, *Euphorbia*), vines and from lower parts of hedges and trees (*Hibiscus*, *Bauhinia*, *Tabebuia*, *Delonix*). Small arthropods are collected from plant surfaces or hawked for in air.**Breeding.** Breeds all year round, chiefly Mar-Jun. Nest cup-shaped, build on thin branch of shrub or vine 1-3 m above ground, often shaded by leaves. Nest interior lined with soft plant fibre, outside decorated with pieces of dead leaves, lichens or bark. Clutch size 2; incubation 17-19 days, by female; chick darkish grey, two dorsal rows of down; fledging

period 19-21 days; young remain with female for 3-4 weeks; single brood. First breeding in second year.

Movements. Sedentary, with possible dispersal to higher altitudes in Jul/Aug. Race *exilis* is rare straggler to Florida, USA.**Status and Conservation.** Not globally threatened. CITES II. Restricted-range species: present in Puerto Rico and the Virgin Islands EBA and Lesser Antilles EBA. Common resident. Particularly common at sea-level, with densities of at least 6-10 pairs/km² on St Lucia, at least 4-8 pairs/km² on Guadeloupe, and at least 3-5 pairs/km² on Dominica. Widespread throughout Lesser Antilles, occurring at all altitudes and in all habitat types; ready occupation of man-made habitats suggests that habitat loss is unlikely to be a problem.**Bibliography.** Anon. (1998a), Biaggi (1983), Bond (1985), Bos (1989), Chávez-Ramírez & Tan (1993), DeBenedictis (1992), English (1928, 1934), Ingels (1976a, 1976b), Keith (1997), Krüger *et al.* (1982), Lack (1973), Leck (1973), Oberholser (1905), Pulich (1968), Raffaele (1989), Raffaele *et al.* (1998), Riley (1904), Rutgers & Norris (1972), Schuchmann (1979b, 1980c, 1981), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Tyrrell & Tyrrell (1990), Wolf (1975c).Genus *KLAIS* Reichenbach, 1854

70. Violet-headed Hummingbird

Klais guimeti

French: Colibri à tête violette

German: Violettekopfkolibri

Spanish: Colibrí Cabeciazul

Other common names: Violet-crowned Hummingbird(!)

Taxonomy. *Trochilus Guimeti* Bourcier, 1843, Caracas, Venezuela.Genus sometimes merged into *Abeillia*; closely related to *Stephanoxis*. Nominate and race *pallidiventr* intergrade in SE Ecuador. Three subspecies recognized.**Subspecies and Distribution.***K. g. merrittii* (Lawrence, 1860) - E Honduras to E Panama.*K. g. guimeti* (Bourcier, 1843) - N & W Venezuela through E Colombia and Ecuador to extreme N & NE Peru and extreme NW & N Brazil.*K. g. pallidiventr* Stolzmann, 1926 - E Peru and WC Bolivia.**Descriptive notes.** 7.5-8.5 cm; male 2-9 g, female 2-7 g. Bill of female averages slightly longer, but male has significantly longer wings and tail; bill black. Bronzy-green above, pale grey below; entire head (male) or crown (female) violet-blue; square white postocular spot more prominent than in other small hummingbirds; lateral rectrices black, subterminally tipped with dull white, more broadly in female. Young bird resembles adult female but with little or no blue or violet on crown. Racial variation is relatively slight: both sexes of race *merrittii* have crown distinctly bluish rather than violet; underparts of *pallidiventr* are

paler than those of other races.

Habitat. Canopy and edge of tall humid forest, tall second growth, tree plantations, shaded gardens and hedgerows in foothills and adjacent lowlands; mostly below 600 m (Honduras); 50-1200 m (Costa Rica); 400-1800 m (Colombia), 150-1900 m (Venezuela).**Food and Feeding.** Visits mostly small flowers of a variety of trees (*Inga*, *Warscewiczia*, *Hamelia*, *Hampea*, *Vismia*), shrubs (*Cephaelis*, *Psychotria*, *Besleria*, *Sabicea*, *Stachytarpheta*) and epiphytes (*Columnnea*, *Cavendishia*, bromeliads); male often territorial at flowers outside breeding season when not supplanted by larger, more aggressive species. Sallies from perch to catch flies and gnats, gleans foliage for arthropods, especially along edges and streams.**Breeding.** Mainly during dry season, Jan-May in Costa Rica. During breeding season males typically in leks of up to 10 but occasionally solitary. Nest a tiny, thick-walled cup of green moss and cobwebs, lined with soft plant down, typically on pendent twig or vine overhanging shaded stream, less often in forest understorey far from water, 1-5 m above ground. Clutch size 2; incubation at least 16 days. No further information.**Movements.** Basically sedentary, but performs some local movements in response to changing flower availability.**Status and Conservation.** Not globally threatened. CITES II. Common in many areas in Central America, such as La Selva Biological Station and Rara Avis reserve in Costa Rica; fairly common to uncommon in E Honduras; rare and possibly local in Colombia. Present in Corcovado and Braulio Carrillo National Parks and Golfito National Wildlife Refuge (Costa Rica), Los Katios National Park (Colombia) and Guatopo National Park (Venezuela).**Bibliography.** Bond & Meyer de Schauensee (1943), Butler (1979), Fogden (1993), Grantsau (1988), Hilty & Brown (1986), Howell, S.N.G. & Webb (1995a), Howell, T.R. (1957), Meyer de Schauensee & Phelps (1978), Monroe (1968), Moore (1950a), Parker *et al.* (1982), Remsen & Traylor (1989), Ridgely & Gwynne (1989), Ridgway (1911), Ruschi (1968, 1981-1982, 1986), Salaman & Mazariegos (1998b), Sick (1993, 1997), Skutch (1958), Slud (1964), Stiles (1980, 1985b), Stiles & Skutch (1989), Stone (1996), Stotz *et al.* (1996), Wetmore (1939, 1968a), Williams & Tobias (1994), Zimmer (1950d).

Genus *STEPHANOXIS* Simon, 1897

71. Plovercrest

Stephanoxis lalandi

French: Colibri de Delalande **German:** Spitzhaubenelfe **Spanish:** Colibrí Copetón
Other common names: Black-breasted/DeLalande's Plovercrest (*lalandi*); Violet-crested/Loddiges's Plovercrest (*loddigesii*)

Taxonomy. *Trochilus Lalandi* Vieillot, 1818, Brazil.

Genus closely related to *Klais*. Race *loddigesii* sometimes considered a distinct species, on basis of marked plumage differences. Species name has on occasion been erroneously emended to "*delalandei*". Two subspecies recognized.

Subspecies and Distribution.

S. l. lalandi (Vieillot, 1818) - E Brazil (S Minas Gerais, Espírito Santo, Rio de Janeiro, NE São Paulo).

S. l. loddigesii (Gould, 1831) - E Paraguay and NE Argentina (Misiones) to S Brazil (S São Paulo, Paraná, Santa Catarina, Rio Grande do Sul).

Descriptive notes. 8.5-9 cm; male 3.4 g, female 2.2 g. Male has bill straight, black; head with long iridescent green crest, occasionally crest bluish green, longest crest feather purplish black; sides of head grey, white spot behind the eye; upperparts shining bronze-green; chin to upper belly violet-blue, rest of underparts grey; central tail feathers green, outer ones green with subterminal blackish band, tipped greyish white. Female shining green above, grey below; head feathers slightly elongated. Immature like female. Race *loddigesii* has bill slightly longer; male differs from nominate by blue crest and more reduced, darker patch on

underparts: female similar to that of nominate.

Habitat. Understorey of forest, scrub vegetation and along water courses from sea-level to 900 m, occasionally seen at much higher altitudes (Serra do Caparão, Espírito Santo, 2900 m).

Food and Feeding. Forages for nectar at native and introduced flowers (*Vochysia*, *Salvia*, *Dombeya*, *Calliandra*, *Inga*, *Eucalyptus*), from near the ground to tree tops. Insects are caught in the air, also gleaned from leaves. Male establishes feeding territories mainly during reproductive period.

Breeding. Oct-Mar. Males gather at leks during the reproductive period. Cup-shaped nest of soft plant or seed fibres and cobweb is placed on forked branch in sheltered shrub or bamboo at 1-3 m. Clutch size 2; incubation 14-16 days, by female; chick has pale grey dorsal down; fledging at 24-28 days; young remain with adult for 3 weeks; one brood per year. First breeding in second year.

Movements. Largely sedentary, but in the south of breeding range individuals winter at lower elevation.

Status and Conservation. Not globally threatened. CITES II. Patchily distributed and only locally common, e.g. around Pôrto Alegre in Rio Grande do Sul (S Brazil). In C & S Paraná (along R Tibagi) densities of at least 3-5 pairs/km² noted in breeding season. Readily takes to man-made habitats such as farmland with scattered bushes and forest islands. Present in Serra dos Órgãos and Itatiaia National Parks (Brazil) and Estancia Itabo Private National Park and Mbaracayú Reserve (Paraguay).

Bibliography. Belton (1984), Berry (1989), Brooks *et al.* (1993), Canevari *et al.* (1991), Contreras *et al.* (1992), Forrester (1993), Grantsau (1988), Hayes (1995), Lowen, Bartrina, Clay & Tobias (1996), Lowen, Clay *et al.* (1995), Narosky & Yzurieta (1993), Navas & Bo (1993), Oniki (1996), Parker & Goerck (1997), de la Peña (1994), Pereyra (1950), do Rosário (1996), Ruschi (1973d, 1981-1982, 1982a, 1986), Rutgers & Norris (1972), Saibene *et al.* (1996), Sazima, I. *et al.* (1996), Sazima, M. *et al.* (1994), Scott & Brooke (1985), Sick (1993, 1997), Stotz *et al.* (1996), Tobias *et al.* (1993), Willis (1992).

Genus *ABEILLIA* Bonaparte, 1850

72. Emerald-chinned Hummingbird

Abeillia abeillei

French: Colibrí d'Abeillé **German:** Smaragdkehlkolibri **Spanish:** Colibrí de Abeillé
Other common names: Abeille's Hummingbird

Taxonomy. *Ornismya Abeillei* Lesson and DeLattre, 1839, Veracruz, Mexico.

Genus sometimes considered to incorporate *Klais*. Validity of race *aurea* has been questioned. Two subspecies recognized.

Subspecies and Distribution.

A. a. abeillei (Lesson & DeLattre, 1839) - SE Mexico to Guatemala, El Salvador and N Honduras.
A. a. aurea A. H. Miller & Griscom, 1925 - S Honduras and N Nicaragua.

Descriptive notes. 7-7.5 cm; 2.7 g. Male has short straight black bill; back metallic bronze-green; broad white postocular spot; chin and upper throat shining emerald green, lower throat blackish, rest of underparts dull greenish grey; inner tail feathers blue-green, outer ones blackish tipped grey. Female similar to male but entirely grey below. Immature resembles adult female. Race *aurea* smaller, with upperparts more bronze or golden, less green.

Habitat. Occurs in open understorey of higher tropical to cloudforest. Forages very low above ground. Occasionally seen at forest edges, but

rare in open vegetation. Most numerous at c. 1000-2200 m.

Food and Feeding. Nectar of flowering Rubiaceae, Verbenaceae, Oenotheraceae. Feeds on insects by hawking. Male defends nectar-rich flower stands.

Breeding. Feb-Mar. Deep, cup-shaped nest constructed of soft plant fibre and cobweb on vertical shoots at 2-3 m. No further data available.

Movements. Sedentary.

Status and Conservation. Not globally threatened. CITES II. Common resident on the Atlantic and Pacific slopes. Appears to have declined locally in N Oaxaca, Mexico, due to habitat destruction by logging. Regularly recorded at Valle Nacional, Lagos de Montebello and El Triunfo Biosphere Reserve (Mexico).

Bibliography. Anon. (1998a), Binford (1989), Friedmann *et al.* (1950), González-García (1993), Howell & Webb (1995a), Johnsgard (1997), Land (1970), Miller & Griscom (1925b), Monroe (1968), Paynter (1957), Ridgway (1911), Stotz *et al.* (1996), Wagner (1946a, 1957b).

Genus *LOPHORNIS* Lesson, 1829

73. Tufted Coquette

Lophornis ornatus

French: Coquette huppe-col **German:** Schmuckelfe
Other common names: Splendid Coquette

Spanish: Coqueta Adornada

Taxonomy. *Trochilus ornatus* Boddaert, 1783, Cayenne. Monotypic.

Distribution. E Venezuela, Trinidad and the Guianas to N Brazil.

Descriptive notes. 6-8-7 cm; 2.3-2.8 g. Male has short straight bill, red, tipped black; forehead iridescent green, crest long, dark rufous, rest of upperparts shining pale green, rump with buffy white band, uppertail-coverts purplish; long tufts (elongated feathers springing fan-like from cheeks) rufous, each with green iridescent spot at distal end, throat glittering emerald-green, rest of underparts pale green; tail squared, central rectrices bronzy-green, remainder rufous with bronzy-green tips and edges. Female lacks crest and tufts, rump buff; underparts rufous, with green flanks. Immature resembles adult female.

Habitat. Edges of humid forest, gallery forest, thickets, cultivated areas like plantations, and savannas, at 100-1000 m.

Food and Feeding. Feeds on arthropods and on nectar of flowering Acanthaceae, Asclepiadaceae (*Asclepias*), Compositae, Euphorbiaceae, Labiatae, Marantaceae, Myrtaceae, Rubiaceae and Verbenaceae (*Stachytarpheta*). Feeds by trap-lining.

Breeding. Dry season in Trinidad, Jan-Apr; Dec-Mar in Guyana. Nest cup-shaped, built out of fine and soft plant fibres, placed c. 2 m above ground. Clutch size 2; incubation by female 13-14 days; fledging at 20 days.

Movements. Sedentary.

Status and Conservation. Not globally threatened. CITES II. Common. Accepts man-made habitats like plantations. Occurs in several protected areas such as Paria Peninsula National Park (Venezuela) and Asa Wright Nature Centre (Trinidad). Regularly recorded in Kanuku Mts of SW Guyana. During recent decades has been imported into Europe for wild bird trade but this has now been ended.

Bibliography. Allen (1961), Bangs & Penard (1918), Berlepsch (1908), Chubb (1916), Cordier (1982), French (1991), Gilliard (1941), Grantsau (1988), Haverschmidt & Mees (1994), Herklots (1961), Meyer de Schauensee (1982), Meyer de Schauensee & Phelps (1978), Olrog (1968), Ruschi (1981-1982, 1982a, 1986), Schuchmann-Wegert & Schuchmann (1986), Sick (1993, 1997), Snyder (1966), Stotz *et al.* (1996), Tostain *et al.* (1992).

74. Dot-eared Coquette

Lophornis gouldii

French: Coquette de Gould

German: Gouldelfe

Spanish: Coqueta Moteada

Taxonomy. *Ornismya gouldii* Lesson, 1833, no locality. Monotypic.

Distribution. NC & C Brazil (Pará and Maranhão to Mato Grosso and Goiás) to E Bolivia (Santa Cruz).

Descriptive notes. 6-8-7.6 cm; 2.5-2.8 g. Male has short straight bill, red, tipped black; forehead glittering golden green, crest dark rufous, remainder of upperparts bronzy-green, white band across rump; throat glittering emerald-green, tufts (elongated feathers springing fan-like from cheeks) white with shining green spots distally, rest of underparts greyish-green; tail squared, central rectrices bronzy-green, remainder rufous with bronzy-green tips and edges. Female lacks tufts and crest; similar to male above, but with more bronze iridescence; throat rufous, below washed greyish-green; tail square, dark bronze distally rufous. Immature resembles adult female.

Habitat. Forest edges, savanna and *cerrado* up to 500 m.

Food and Feeding. No specific data available. Presumably feeds on nectar of similar flowers visited by *L. ornatus*; trap-liner.

Breeding. Dec-Apr. Nest undescribed; clutch size 2; incubation 14 days, by female; fledging period 22 days.

Movements. No information; presumably sedentary.

Status and Conservation. Not globally threatened. CITES II. No life-history data available; may take to man-made habitats to some extent. Occurs in Chapada dos Guimarães National Park, Mato Grosso (WC Brazil). Frequently recorded in Serra dos Carajás, Pará (NC Brazil).

Bibliography. Berlioz (1964), Forrester (1993), Grantsau (1988), Meyer de Schauensee (1982), Olrog (1968), Remsen & Traylor (1989), Ruschi (1953a, 1967a, 1981-1982, 1982a, 1986), Schuchmann-Wegert & Schuchmann (1986), Sick (1993, 1997), Stotz *et al.* (1996), Wilkinson (1996).

75. Frilled Coquette

Lophornis magnificus

French: Coquette magnifique

German: Prachtelfe

Spanish: Coqueta Magnífica

Taxonomy. *Trochilus magnificus* Vieillot, 1817, Brazil.

Monotypic.

Distribution. CE Brazil, from Espírito Santo S to Santa Catarina, and W to Goiás and Mato Grosso; irregularly N to Alagoas, where status uncertain.

Descriptive notes. 7.1-7.7 cm; c. 3 g, records of 1-2 and 1-8 g presumably referring to juveniles. Male has short straight bill, red, tipped black; forehead iridescent green, crest rufous, rest of upperparts bronzy-green, white band across rump; throat glittering emerald green, tufts (elongated feathers fanning out from cheeks and side of throat) shorter than in *L. gouldii*, fan-shaped, white with shining green distal band, rufous at base; rest of underparts greyish-green; tail squared, central rectrices bronzy green, remaining rufous with bronzy green tips and edges. Female lacks tufts and crest, upperparts similar to male; throat and crest, below washed greyish-green; tail squared,

with rufous discs and some white with dark crescents, below washed greyish-green; tail squared, dark bronzy, distally rufous. Immature resembles adult female.

Habitat. Edges of humid forest, second growth, coffee plantations, and *cerrado* up to 1000 m.

Food and Feeding. Feeds on arthropods and nectar of small flowering plants like *Cirrus*, *Duranta arborensis*, introduced *Eucalyptus*, *Genipa americana*, *Hibiscus*, *Inga affinis*, *Lantana camara*, *L. lilacina*, *L. brasiliensis*, *Leonurus siribicus*, *Myrciaria cauliflora*, *Palicourea*, *Psychotria maregravii*, *Tilandsia*. Subordinate to other larger hummingbirds.

Breeding. Aug-Mar. Cup-shaped nest built out of fine plant down and moss, decorated with green and whitish lichens on the outside, 2-5 m above ground, saddled on branches in bushes or small trees. Clutch size 2; incubation 12-13 days by female; fledging at 20 days.

Movements. Some seasonal dispersal, possibly following flowering and reproductive season.

Status and Conservation. Not globally threatened. CITES II. Common. Readily accepts man-made habitats like plantations and flowering gardens and other disturbed areas like second growth. Occurs in Nova Lombardia and Santa Lúcia Biological Reserves (Espírito Santo); also recorded in Pedra Talhada State Park (Alagoas). Many individuals imported to Europe over recent decades for cage-bird trade; importation now under national and international regulations.

Bibliography. de Almeida & Ruschi (1976), Belton (1984), Dubs (1992), Forrester (1993), Grantsau (1988), Mobbs (1972a), Oniki (1996), Oniki & Willis (1998), Parker & Goerck (1997), do Rosário (1996), Ruschi (1949b, 1973d, 1981-1982, 1982a, 1982b, 1986), Rutgers & Norris (1972), Sargeant (1996), Schuchmann-Wegert & Schuchmann (1986), Scott & Brooke (1985), Sick (1993, 1997), Sick & Pabst (1968), Stotz *et al.* (1996), Teixeira *et al.* (1987), Tobias *et al.* (1993), Wittmann (1982).

76. Short-crested Coquette

Lophornis brachylophus

French: Coquette du Guerrero

German: Kurzhaubenelfe

Spanish: Coqueta de Guerrero

Taxonomy. *Lophornis delattrei brachylophus* R. T. Moore, 1949, San Vicente de Benítez, Guerrero, Mexico. Forms a superspecies with *L. delattrei* and possibly *L. stictolophus*; has been considered conspecific with former. Monotypic.

Distribution. Sierra Madre del Sur in Guerrero (SW Mexico).

Descriptive notes. 7-7.5 cm. Male has short, straight bill, black; crest short (c. 1-2 cm), filamentous, rufous, longest feathers tipped green; rest of upperparts deep emerald green, white band across rump, lower rump bronzy-purple, uppertail-coverts green; throat iridescent emerald green, cheek tufts not as conspicuous as in other congeners, short, rufous with iridescent green distal band; whitish band below throat, rest of underparts pale cinnamon; tail double-rounded, central pair of rectrices green, remainder cinnamon-rufous, tipped black. Female lacks crest and tufts, forehead dull cinnamon, upperparts pale green; buffy to whitish

band across rump, lower rump duller; throat whitish, bordered by white band, lower underparts pale cinnamon; tail rounded, central pair of rectrices green, tipped blackish, others cinnamon with blackish subterminal bar, tips pale buff. Immature resembles adult female.

Habitat. Semi-deciduous forest, humid evergreen forest, pine-oak forest, and plantations at 900-1800 m.

Food and Feeding. Feeds on nectar of flowering *Cecropia*, *Clethra*, *Conostegia*, *Inga* and other small flowering plants. Hawks in the air for arthropods.

Breeding. Probably Nov-Feb. No further data available.

Movements. Sedentary with some altitudinal movements likely.

Status and Conservation. **ENDANGERED.** CITES II. Restricted-range species; present in Sierra Madre del Sur EBA. Rare to locally common. Species is restricted to a small area about 40 km across, and it is only recorded frequently between the villages of Arroyo Grande, Paraíso and Nueva Delhi, Guerrero. The habitat is unprotected and under severe threat of deforestation for agricultural purposes such as corn and coffee cultivation. To date no plans exist for the protection of this forest type.

Bibliography. Anon. (1998a), Banks (1990), Blake (1953), Ceballos-Lascurain (1989), Collar *et al.* (1992), Friedmann *et al.* (1950), Hernández-Baños *et al.* (1995), Howell (1989a, 1989c, 1992), Howell & Webb (1995a), Johnson (1997), Moore (1949), Navarro (1992), Navarro *et al.* (1991), Ornelas (1987), Schuchmann (1990b), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Wege & Long (1995).

77. Rufous-crested Coquette

Lophornis delattrei

French: Coquette de Delattre

German: Zierelfe

Spanish: Coqueta Crestirrufa

Other common names: Dusky Coquette ("melanie")

Taxonomy. *Ornismya* (*Lophorinus*) *DeLattrei* Lesson, 1839, no locality = Moyobamba, Peru. Forms a superspecies with *L. brachylophus* and possibly *L. stictolophus*; has been considered conspecific with former. Proposed species "*L. melaniae*", apparently from Colombia, probably represents aberrant individuals or faded skins of present species; it is not, as previously reported, melanistic. Bolivian birds were tentatively split as race *regulus*, but, despite some possible differences in female plumage, probably best treated as synonym of nominate. Two subspecies recognized.

Subspecies and Distribution.

L. d. lessoni Simon, 1921 - Pacific and Caribbean slopes of SW Costa Rica and Panama, and C & E Andes of Colombia (Magdalena Valley and Santander).
L. d. delattrei (Lesson, 1839) - E Peru and N Bolivia (to Beni and Santa Cruz).

Descriptive notes. 6.4-7 cm; c. 2.8 g. Male has short straight bill, red, tipped black; crest long (c. 2 cm) filamentous, rufous, green tips distally; rest of upperparts bronzy-green with white band across rump, lower rump and uppertail-coverts purplish-bronze; throat glittering green, cheek tufts not as conspicuous as in other congeners, rufous with broad iridescent green distal band, throat subtended by some white pointed feathers, rest of underparts bronzy green; tail double-rounded, central pair of rectrices green, remainder cinnamon-rufous, tipped black and edged green. Female lacks crest and tufts, forehead dull cinnamon-rufous, upperparts similar

to male; throat buffy to pale rufous with bronzy discs distally, rest of underparts similar to male but duller; tail rounded, central pair of rectrices green, tipped blackish, others cinnamon with blackish subterminal bar, tips pale buff. Immature resembles adult female but throat greyish. Race *lessoni* has more sharply pointed crest feathers with green almost absent, white terminal throat feathers less pointed. **Habitat.** Edges of humid forest, clearings, along roadsides, and semi-open habitats with bushes, at 600-2000 m. Forages at lower levels.

Food and Feeding. Feeds on nectar of flowering *Inga*, Myrtaceae, Verbenaceae and other small flowering plants. Arthropods are caught in the air by hawking.

Breeding. No information available; presumably breeds during drier season like congeners.

Movements. Sedentary.

Status and Conservation. Not globally threatened. CITES II. Generally rare, though not restricted to forest habitats, and therefore not affected directly by extensive deforestation within its range. Occurs in Beni Biosphere Reserve (NC Bolivia).

Bibliography. Anon. (1998a), Banks (1990), Best *et al.* (1997), Bond & Meyer de Schauensee (1943), Floerike (1920), Hilty & Brown (1986), Johnsgard (1997), Parker *et al.* (1982), Remsen & Traylor (1989), Ridgely & Gwynne (1989), Ridgway (1911), Schuchmann (1990b), Schuchmann-Wegert & Schuchmann (1986), Slud (1964), Stiles (1985c), Stiles & Skutch (1989), Stotz *et al.* (1996), Walters (1997), Wetmore (1968a), Willis & Eisenmann (1979), Zimmer (1950d).

78. Spangled Coquette

Lophornis stictolophus

French: Coquette pailletée

German: Glanzelfe

Spanish: Coqueta Coronada

Taxonomy. *Lophornis stictolophus* Salvin and Elliot, 1873, Antioquia, Colombia.

Possibly forms a superspecies with *L. brachylophus* and *L. delattrei*. "*L. insignibarb*", known from a single Bogotá trade skin and sometimes awarded monospecific genus *Lithiophanes*, may be a hybrid of present species and *L. chalybeus verreauxii*, although apparently characters do not fit precisely with either. Monotypic.

Distribution. W Venezuela through E Colombia and E Ecuador to N Peru (Marañón Valley).

Descriptive notes. 6.4-6.9 cm. Very similar to *L. delattrei*. Male has short straight bill, red, tipped black; forehead and crest rufous, crest feathers slightly shorter than in *L. delattrei*, broader, distal tips blackish, appearance of crest more bushy; rest of upperparts bronzy-green with white band across rump, lower rump and uppertail-coverts purplish-bronze; throat glittering green, cheek tufts not as conspicuous as in other congeners, rufous with broad iridescent green distal band; throat subtended by some white pointed feathers, rest of underparts bronzy-green; tail double-rounded, central pair of rectrices green, remainder cinnamon-rufous, tipped black. Female lacks crest and tufts, forehead dull cinnamon-rufous, upperparts similar to male; throat whitish with large rufous spots, belly cinnamon often with some green discs; tail rounded, central pair of rectrices green, rest cinnamon basally, all with blackish subterminal bar, tips buff. Immature resembles adult female but throat greyish.

Habitat. Edge of humid forest, clearings, *cerrado* and drier scrubby areas, up to 1300 m. Usually found below range of *L. delattrei* which it may replace ecologically.

Food and Feeding. No specific data available but possibly feeds on nectar of similar flowers as *L. delattrei*, including *Inga*, *Lantana*, Verbenaceae and Myrtaceae. Takes arthropods in the air by hawking.

Breeding. No information available.

Movements. Sedentary.

Status and Conservation. Not globally threatened. CITES II. Currently considered Near-threatened. Generally rare, but no immediate threats recorded so far. Like *L. delattrei* this species is not restricted to forest habitats and may accept man-made habitats to some extent. Recorded near Santo Domingo, Mérida (Venezuela) and at Panacocha (NE Ecuador).

Bibliography. Best *et al.* (1997), Butler (1979), Hilty & Brown (1986), Meyer de Schauensee (1982), Meyer de Schauensee & Phelps (1978), Olrog (1968), Parker *et al.* (1982), Rahbek *et al.* (1995), Schuchmann-Wegert & Schuchmann (1986), Stotz *et al.* (1996), Zimmer (1950d).

79. Festive Coquette

Lophornis chalybeus

French: Coquette chalybée

German: Schmetterlingselfe

Spanish: Coqueta Verde

Other common names: Butterfly Coquette (*verreauxii*)

Taxonomy. *Trochilus chalybeus* Vieillot, 1823, Brazil.

Together with its sister species, *L. pavoninus*, formerly placed in a separate genus, *Polemistria*. Disjunct distribution and morphological differences between S nominate and N races suggest they might be approaching species threshold. "*L. insignibarb*", known from a single Bogotá trade skin and sometimes awarded monospecific genus *Lithiophanes*, may be a hybrid of race *verreauxii* and *L. stictolophus*, although apparently characters do not fit precisely with either. Three subspecies recognized.

Subspecies and Distribution.

L. c. klagesi Berlepsch & Hartert, 1902 - SE Venezuela.

L. c. verreauxii J. Verreaux & E. Verreaux, 1853 - E Colombia, E Ecuador and E Peru to NW Brazil and C Bolivia.

L. c. chalybeus (Vieillot, 1823) - SE Brazil (Espírito Santo, Minas Gerais, Santa Catarina).

Descriptive notes. 7.6-8.5 cm; c. 3 g (record of 2.2 g presumably refers to juvenile). Male has short, straight black bill; cheeks blackish, forehead iridescent green bordered by black band consisting of stiff feathers, rest of upperparts bronzy-green with white bar across rump, lower rump and uppertail-coverts purplish-bronze; cheek tufts green tipped white, breast whitish with dark streaking, belly greyish-brown with blackish central stripe; tail purplish-copper. Female lacks tufts, upperparts like male but lacks glittering frontlet; chin whitish-buff forming a white moustachial stripe, rest of underparts brownish scaled whitish; tail similar to that of male, outer pairs of rectrices tipped greyish to buff. Immature resembles adult female. Race *verreauxii* has hindcrown elongated by filamentous feathers, green crest, throat and belly blackish-green; *klagesi* is dark green above, uppertail-coverts bronzy-olive, white tips on tufts smaller, rectrices bronzy-green, female generally darker, tips on rectrices smaller and darker.

Habitat. Humid forest, second growth and *cerrado*, at 100-1000 m.

Food and Feeding. Feeds on nectar of flowering Acanthaceae, Bromeliaceae, Compositae, Malvaceae, Myrtaceae, Rubiaceae and Vochysiaceae. Arthropods are possibly gleaned from foliage.

Breeding. Aug-Nov. Nest cup-shaped, constructed of fine soft plant down, saddled at the end of branches in small trees 2-5 m above ground. Clutch size 2; incubation period 13-14 days by female; fledging at 22 days.

Movements. Sedentary, with some seasonal short-distance dispersal most likely. Single record from NE Argentina (Buenos Aires).

Status and Conservation. Not globally threatened. CITES II. No information on abundance available. Part of habitat under threat of deforestation. Occurs in Tambopata Reserve (SE Peru) and Itatiaia and Marumbi National Parks (SE Brazil).

Bibliography. Allen (1995), Best *et al.* (1997), Bond & Meyer de Schauensee (1943), Butler (1979), Canevari *et al.* (1991), Donahue (1994), Grantsau (1988), Gyldestolpe (1945b), Hilty & Brown (1986), Meyer de Schauensee & Phelps (1978), Olrog (1972, 1979b), Parker *et al.* (1982), de la Peña (1994), Remsen & Traylor (1989), do Rosário (1996), Ruschi (1953a, 1953b, 1962c, 1981-1982, 1982a, 1986), Salvador & Salvador (1990), Schuchmann-Wegert & Schuchmann (1986), Sick (1993, 1997), Stotz *et al.* (1996), Terborgh *et al.* (1984), Zimmer (1950d).

80. Peacock Coquette

Lophornis pavoninus

French: Coquette paon

German: Pfauenelfe

Spanish: Coqueta Pavonina

Taxonomy. *Lophornis pavoninus* Salvin and Godman, 1882, Merumé Mountains, Guyana.

Together with its sister species, *L. chalybeus*, formerly placed in a separate genus, *Polemistria*. Proposed race *punctigula* (Cerro Paritepui), described on basis of slight differences in female plumage, best considered synonymous with nominate. Two subspecies recognized.

Subspecies and Distribution.

L. p. pavoninus Salvin & Godman, 1882 - Cerro Paritepui (SE Venezuela), Mt Roraima (SE Venezuela/NC Brazil) and Merumé Mts (Guyana).

L. p. duidae Chapman, 1929 - Mt Duida and adjacent smaller tepuis in SE Venezuela.

Descriptive notes. c. 9-7 cm. Male has short, straight black bill; head glittering golden green with median black line, upperparts shining dark green with white band across rump; throat black, cheek tufts broad, shining green with large blackish-blue spots at distal end, proximally rufous with white spot, rest of underparts greyish-green; tail slightly forked, purplish-bronze. Female lacks tufts; upperparts golden bronzy with buffy white band across rump; throat white with black streaks, lateral feathers elongated, black and white, rest of underparts mottled black, white and green; tail greyish with broad purplish-bronze subterminal bar, outer pair of rectrices tipped whitish. Immature resembles adult female. Race *duidae* has black median line on crown narrow; rufous at base of cheek-fans reduced, and lacks white.

Habitat. Rainforest, cloudforest, clearings and forest edge, at 500-2000 m. Forages alone or in small groups in canopy.

Food and Feeding. Feeds on nectar of flowering *Inga*, *Lantana*, *Rubus*, *Salvia*, Bromeliaceae, Rutaceae and Compositae. Arthropods are possibly gleaned from foliage.

Breeding. No information on season; nest cup-shaped, suspended on horizontal branches c. 2 m above ground. Clutch size 2; incubation 13-14 days, by female; fledging at 20 days.

Movements. Sedentary.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species: present in Tepuis EBA. Forest habitat on top of tepuis still remain pristine. However, during the last few years adventure tourism, including para-gliding, on Mt Roraima and other tepuis has increased steadily, but so far no immediate threat has been detected. Present species seems not to inhabit man-made habitats and other disturbed areas. Frequently recorded in the Escalera area, Bolívar (S Venezuela).

Bibliography. Chapman (1929), Chubb (1916), Dickerman & Phelps (1982), Forrester (1993), Grantsau (1988), Mayr & Phelps (1967), Meyer de Schauensee (1982), Meyer de Schauensee & Phelps (1978), Olrog (1968), Ruschi (1981-1982, 1982a, 1986), Schuchmann-Wegert & Schuchmann (1986), Sick (1993), Snyder (1966), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Zimmer & Phelps (1946).

81. Black-crested Coquette

Lophornis helenae

French: Coquette d'Hélène **German:** Schwarzschoepfelfe **Spanish:** Coqueta Crestinegra
Other common names: Princess Helena's Coquette

Taxonomy. *Ornismya Helena* DeLattre, 1843, Vera Paz, Guatemala. Together with its sister species, *L. adorabilis*, formerly placed in a separate genus, *Paphosia*. Monotypic.

Distribution. S Mexico (Veracruz, Oaxaca, Chiapas) S to E Costa Rica.

Descriptive notes. 6.4-7 cm; male and female 2.6-2.8 g. Male has short straight bill, red, tipped black; crown iridescent green, wispy crest hair-like, black, rest of upperparts bronzy-green with whitish band across rump, lower rump blackish; throat iridescent green, breast black, elongated lateral feathers buff on inner web, bronzy breast band, belly white with large iridescent bronzy discs; tail slightly forked, central rectrices dark green, remainder rufous, edged dusky green. Female lacks crest, upper mandible black, lower red, tipped black; head blackish, cheeks black, upperparts bronzy-green with buffy white band across rump, lower

rump blackish; throat buffy white with bronzy discs, rest of underparts whitish with large bronzy discs, undertail-coverts cinnamon; tail rounded, dusky green, subterminal bar blackish, outer rectrices tipped cinnamon. Immature resembles adult female.

Habitat. Semi-open habitats, forest edge, second growth, gaps and plantations at 100-1200 m. Forages usually at canopy level.

Food and Feeding. Feeds on nectar of flowering *Clusia*, *Cordia*, *Dipteryx*, *Hampea*, *Hymenolobium*, *Norantea* and *Vochysia*. Gleans arthropods from foliage and twigs. Subordinate to other larger hummingbirds; feeds using trap-lining technique.

Breeding. Nest found in Mar; small, cup-shaped at end of twig 8 m above ground. No further information available.

Movements. Sedentary, with irregular seasonal altitudinal dispersal.

Status and Conservation. Not globally threatened. CITES II. Generally uncommon. May accept man-made habitats like plantations to some extent. Species has been recorded in Sierra de Los Tuxtlas (Veracruz), and at Lagos de Montebello and on the Mayan ruins of Bonampak (Chiapas).

Bibliography. Anon. (1998a), Barlow *et al.* (1969), Binford (1989), Brown & Bowers (1985), Fogden (1993), Friedmann *et al.* (1950), González-García (1993), Howell & Webb (1995a), Johnsgard (1997), Land (1970), Monroe (1968), Rangel-Salazar (1990), Ridgway (1911), Schuchmann-Wegert & Schuchmann (1986), Slud (1964), Stiles (1985b, 1985c), Stiles & Skutch (1989), Stotz *et al.* (1996).

82. White-crested Coquette

Lophornis adorabilis

French: Coquette adorable **German:** Weißschoepfelfe **Spanish:** Coqueta Adorable
Other common names: Adorable Coquette

Taxonomy. *Lophornis adorabilis* Salvin, 1870, Bugaba, Chiriquí. Together with its sister species, *L. helenae*, formerly placed in a separate genus, *Paphosia*. Monotypic.

Distribution. C Costa Rica to W Panama.

Descriptive notes. 7-7.8 cm; c. 2-7 g. Male has short straight bill, red, tipped black; bill heavier than those of congeners; forehead fiery coppery, crest white, rest of upperparts bronzy-green with buffy white band across rump, lower rump and uppertail-coverts purplish-bronzy; throat and hair-like elongated tufts glittering green, breast white, rest of underparts cinnamon-rufous with some green discs on flanks; tail forked, rufous chestnut edged bronzy-green. Female lacks crest and tufts, upper mandible black, lower red, tipped black, upperparts similar to male, slightly duller, black mask; throat and breast white with small bronzy green

discs, rest of underparts cinnamon-rufous; tail has subterminal blackish band. Immature resembles adult female; immature male has some green discs on throat.

Habitat. Humid forest, forest edge, second growth and shaded plantations, at 300-1200 m. Usually forages at canopy level, occasionally descends to lower strata while feeding in second growth and at edges.

Food and Feeding. Feeds on nectar of flowering *Inga*, *Lonchocarpus*, *Stachytarpheta* and *Vochysia*. Arthropods are gleaned from foliage and twigs. Dominated by larger hummingbird species; feeds by trap-lining.

Breeding. Dec-Feb. Nest cup-shaped, constructed of soft plant down, decorated with lichens on exterior, 5-20 m above ground, exposed at end of twigs at forest edge or clearings. Clutch size 2; incubation by female but no exact data on incubation period; fledging at 21-22 days.

Movements. Sedentary, with seasonal altitudinal dispersal.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species; present in South Central American Pacific Slope EBA. Locally common. Takes to man-made habitats such as plantations; not confined to forest habitat which is under some threat of deforestation. No immediate threat so far recorded.

Bibliography. Anon. (1998a), Johnsgard (1997), Ridgely & Gwynne (1989), Schuchmann-Wegert & Schuchmann (1986), Skutch (1961a), Slud (1964), Stattersfield *et al.* (1998), Stiles (1985c), Stiles & Skutch (1989), Stotz *et al.* (1996), Wetmore (1968a).

PLATE 52

inches 2
cm 5

Genus *DISCOSURA* Bonaparte, 1850

83. Wire-crested Thorntail

Discosura popelairii

French: Coquette de Popelaire **German:** Haubenfadenelfe **Spanish:** Rabudito Crestado
Other common names: Popelaire's Coquette

Taxonomy. *Trochilus popelairii* Du Bus de Gisignies, 1846, Peru. Often placed in genus *Popelairia*, along with *D. langsdorffi*, *D. letitia* and *D. conversii*; genus closely related to *Lophornis*. Monotypic.
Distribution. E Colombia, E Ecuador and NE Peru.

Descriptive notes. Male c. 11.4 cm (including long tail), female 7.5-8.2 cm; c. 2.5 g. Male has short straight black bill; crown glittering green with long narrow hair-like crest, rest of upperparts coppery green with white band across rump; gorget iridescent green, underparts black, sides brownish with white patch on flanks; tail long, forked, steely blue, outer rectrices narrow, shafts of all rectrices white. Female upperparts similar but lacking crest; underparts black with white malar streak and patch on flanks; tail short, slightly forked, bluish-black, tipped white. Immature resembles adult female.

Habitat. Humid forest and edges at 500-1200 m. Usually forages in canopy.
Food and Feeding. Feeds on nectar of flowering *Inga* trees; also takes arthropods.
Breeding. One nest in Apr (Colombia) saddled at end of branch 8 m above ground.
Movements. No information available. Probably sedentary.
Status and Conservation. Not globally threatened. CITES II. Generally rare. Does not seem partial to man-made habitats; habitat within range under severe threat of destruction. In NE Ecuador, regularly recorded between Tena and Coca.
Bibliography. Best *et al.* (1997), Bloch *et al.* (1991), Butler (1979), Cordier (1982), Hilty & Brown (1986), Meyer de Schauensee (1966, 1982), Olrog (1968), Parker *et al.* (1982), Salaman & Mazariegos (1998a, 1998b), Schuchmann (1976a), Stotz *et al.* (1996), Taczanowski (1884), Terborgh *et al.* (1984), Williams & Tobias (1994), Wittmann (1982).

84. Black-bellied Thorntail

Discosura langsdorffi

French: Coquette de Langsdorff **German:** Brustband-Fadenelfe **Spanish:** Rabudito Ventrinegro
Other common names: Black-breasted/Langsdorff's Thorntail

Taxonomy. *Trochilus langsdorffi* Temminck, 1821, Brazil. Often placed in genus *Popelairia*, along with *D. popelairii*, *D. letitia* and *D. conversii*; genus closely related to *Lophornis*. Two subspecies recognized.
Subspecies and Distribution.
D. l. melanosternon (Gould, 1868) - SE Colombia and S Venezuela to E Ecuador, E Peru and W Brazil (R Madeira, R Guaporé, R Negro, W Mato Grosso).
D. l. langsdorffi (Temminck, 1821) - E Brazil (Bahia, Espírito Santo, Rio de Janeiro).

Descriptive notes. Male 12-13.7 cm (including long tail), female 7-6 cm; c. 3-2 g. Male has short straight black bill; crown iridescent emerald green, rest of upperparts coppery green with white band across rump; gorget iridescent emerald green, bordered by a golden coppery band, belly black, flanks bronzy-green; tail long, forked, outer rectrices narrow, outer 3 pairs of rectrices grey, shafts of all rectrices white. Female has upperparts similar to male; throat white spangled green and black, small white malar streak, breast spangled green with lower border coppery, belly black with white patch on flanks; tail short and forked, basally

bronze, rest steely blue tipped white. Immature resembles adult female. Race *melanosternon* slightly smaller, with crown grass green, underparts darker, more golden on breast.

Habitat. Humid lowland forest and edges, at 100-300 m. Forages from mid-strata to canopy.
Food and Feeding. Feeds on arthropods and nectar of flowering *Calliandra*, *Inga* trees, *Lantana*, *Mimosa*, *Vochysia*, Bromeliaceae, Compositae, Labiatae, Fabaceae, Malvaceae and Rubiaceae.
Breeding. Nov-Mar. Nest cup-shaped, made out of the soft down of *Typha*, bromeliads and other plant seeds, externally decorated with pieces of lichen; placed on horizontal branch c. 10 m above ground. Clutch size 2; incubation 13 days, by female; fledging at 20 days.
Movements. No information available. Probably sedentary.
Status and Conservation. Not globally threatened. CITES II. Generally considered rare throughout range. Habitat under severe threat of deforestation, and species does not seem to accept man-made habitats. Protected locally in some national parks. Regularly recorded at Panacocha (E Ecuador).
Bibliography. Best *et al.* (1997), Butler (1979), Grantsau (1988), Hilty & Brown (1986), Meyer de Schauensee & Phelps (1978), O'Neill (1974), Parker & Goerck (1997), Parker & Remsen (1987), Parker *et al.* (1982), Remsen & Traylor (1989), Ruschi (1973d, 1981-1982, 1982a, 1986), Salaman & Mazariegos (1998a), Sargeant (1996), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Taczanowski (1884), Zimmer & Hilty (1997), Zimmer *et al.* (1997).

85. Coppery Thorntail

Discosura letitia

French: Coquette de Létitia **German:** Kupferfadenelfe **Spanish:** Rabudito Cobrizo

Taxonomy. *Trochilus letitia* Bourcier and Mulsant, 1852, Bolivia. Often placed in genus *Popelairia*, along with *D. popelairii*, *D. langsdorffi* and *D. conversii*; genus closely related to *Lophornis*. Monotypic.
Distribution. Lowlands of NE Bolivia.

Descriptive notes. c. 9 cm. Male has short, straight black bill, crown iridescent emerald green, rest of upperparts bronzy-green with white band across rump; gorget iridescent emerald green, belly dusky washed with green, flanks bronzy-green; tail long, forked, outer rectrices narrow, purplish-black, shafts of all rectrices whitish. Female unknown.

Habitat. Probably rainforest along rivers.
Food and Feeding. No information available; most likely feeds on nectar of same flowers as congeners.
Breeding. No information available.
Movements. No information available.

Status and Conservation. Not globally threatened. Data-deficient. CITES II. Restricted-range species; precise distribution uncertain. Possibly extinct. Has not been recorded during this century and is known only from three 19th-century specimens. Possibly the least known of all hummingbird species. Urgent action required to verify distributional range and gather information on its life history.

Bibliography. Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Ergueta & de Morales (1996), Meyer de Schauensee (1982), Olrog (1968), Remsen & Traylor (1989), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Wege & Long (1995).

86. Green Thorntail

Discosura conversii

French: Coquette à queue fine **German:** Grüne Fadenelfe **Spanish:** Rabudito Verde

Taxonomy. *Trochilus Conversii* Bourcier and Mulsant, 1846, Bogotá. Often placed in genus *Popelairia*, along with *D. popelairii*, *D. langsdorffi* and *D. letitia*; genus closely related to *Lophornis*. Monotypic.
Distribution. Costa Rica and Panama through W Colombia to W Ecuador.

Descriptive notes. Male c. 10 cm (including long tail), female c. 6-6.7-5 cm; c. 3 g. Male has short, straight bill, black; crown glittering green, rest of upperparts green with white band across rump; underparts shining green with blue centre to breast and white flank patch; tail long, forked, steely blue, outer rectrices narrow, shafts of all rectrices white. Female upperparts similar to male; blackish below with some green discs, white malar streak, green breast band; tail shorter, forked, black, tipped white. Immature resembles adult female.

Habitat. Humid forest, forest edge and at flowering trees in clearings up to 1000 m, occa-

sionally 1400 m. Forages from mid-strata to canopy.

Food and Feeding. Feeds on nectar of flowering *Clusia*, *Inga*, *Mimosa*, *Pithecollobium* and *Warszewiczia*. Gleans insects and spiders from undersurface of larger canopy leaves.

Breeding. Probably Nov-Apr (Costa Rica). No further information available.
Movements. Sedentary, some seasonal altitudinal dispersal likely.

Status and Conservation. Not globally threatened. CITES II. Uncommon throughout most of range. In common with congeners, restricted to forest habitats which remain under threat of deforestation; does not seem to accept man-made habitats. Species occurs in several protected areas, e.g. Tapantí National Park, Costa Rica. In Ecuador, regularly recorded along old Santo Domingo road and at Tinalandia.

Bibliography. Anon. (1998a), Best *et al.* (1997), Butler (1979), Fogden (1993), Hilty (1997), Hilty & Brown (1986), Kirwan & Marlow (1996), Ridgely & Gwynne (1989), Rutgers & Norris (1972), Salaman & Mazariegos (1998b), Slud (1960, 1964), Stiles (1980, 1985b), Stiles & Skutch (1989), Stotz *et al.* (1996), Wetmore (1968a), Williams & Tobias (1994).

87. Racquet-tailed Coquette

Discosura longicauda

French: Coquette à raquettes **German:** Diskuselfe **Spanish:** Rabudito de Raquetas
Other common names: Brazilian Racquet-tail, Racquet-tailed Hummingbird

Taxonomy. *Trochilus longicauda* J. F. Gmelin, 1788, no locality = Cayenne. Often treated as sole member of genus *Discosura*, the remaining species being separated off in *Popelairia*; genus closely related to *Lophornis*. Monotypic.
Distribution. S Venezuela (Amazonas, Bolívar) and the Guianas to NC Brazil (N Amazonas to Amapá); also NE Brazil (Rio Grande do Norte to Espírito Santo).

Descriptive notes. Male c. 10 cm (including long tail), female c. 7-8 cm; 3-3.7 g. Male has short straight black bill; crown iridescent green, rest of upperparts bronzy-green with buffy white band across rump; throat glittering emerald green, lower breast golden-coppery, belly whitish; tail long, forked, purplish, outer pair of rectrices terminating in a blackish racquet. Female upperparts similar

to male, lacks iridescent parts; throat black, laterally bordered white, breast green, belly buffy white; tail moderately long, slightly forked, grey, subterminal bar dark purple, outer rectrices tipped white. Immature resembles adult female.

Habitat. Humid forest along rivers up to 200 m altitude and scrubby savanna. Forages mainly in canopy.

Food and Feeding. Feeds on nectar of flowering *Anacardium*, *Calliandra*, *Inga*, introduced *Eucalyptus*, *Leonotis*, *Leonurus*, Lorantheaceae, Vochysiaceae, Verbenaceae. Arthropods are gleaned from foliage and spiders' webs.

Breeding. No information on season. Nest cup-shaped, made out of soft plant material, lined with *Typha* seed down, fibres of Bromeliaceae and Gramineae; placed 3-6 m above ground on horizontal branch. Clutch size 2; incubation 13-14 days, by female; fledging period 20-22 days.

Movements. Sedentary.

Status and Conservation. Not globally threatened. CITES II. Rare throughout range. Affected by extensive deforestation in many parts of range, most of which is unprotected; however, species occurs in some protected areas such as Imataca Forest Reserve, Bolívar (Venezuela), and Monte Pascoal National Park, Bahia (Brazil). Does not adapt to man-modified habitats.

Bibliography. Berlepsch (1908), Boesman (1998), Chubb (1916), Forrester (1993), Friedmann (1948), Grantsau (1988), Haverschmidt & Mees (1994), Meyer de Schauensee & Phelps (1978), Ruschi (1953b, 1973d, 1981-1982, 1982a, 1986), Rutgers & Norris (1972), Sargeant (1996), Sick (1993, 1997), Snyder (1966), Stotz *et al.* (1996), Tostain *et al.* (1992).

Genus *TROCHILUS* Linnaeus, 1758

88. Red-billed Streamertail

Trochilus polytmus

French: Colibri à tête noire

Spanish: Colibri Portacintas Piquirrojo

German: Rotschnabel-Jamaikasylyphe

Other common names: Jamaican Doctor Bird, Western Streamertail (Hummingbird)

Taxonomy. *Trochilus Polytmus* Linnaeus, 1758, Jamaica.

Genus closely related to *Chlorostilbon*. Forms a superspecies with *T. scitulus*, with which formerly considered conspecific, but differs in display and voice; occasional hybridization in W John Crow Mts. Monotypic.

Distribution. Jamaica (except extreme E).

Descriptive notes. Male 22-30 cm (including bill 2.3 cm, tail 13-17 cm), 5-2 g; female 10-5 cm, 4-4 g. Male has straight bill, coral red tipped black; head black, lateral crown feathers and ear-coverts elongated beyond nape; body iridescent emerald green, darker on back; tail black, forked, second outermost tail feather very long (streamers), scalloped and fluted on the inside; streamers of perched birds are crossed. Female's bill similar to male's, but duller red, with distal part black; above green; underparts white, lightly spotted on sides of breast and belly; tail centrally green, rest dark blue with contrasting broad white tips, no

streamers. A male morph with red chin has occasionally been found in district of St Andrews (EC Jamaica). Immature has black upper mandible, red only at base of bill; red on bill increases with age; head brownish in immature female.

Habitat. Occurs from sea-level to elfin forest and found in all man-made habitats; forages mainly throughout mid-strata and at forest edge. Most numerous at c. 1000 m; most birds at higher altitudes are not currently breeding.

Food and Feeding. Forages for nectar at native and introduced flowers, including *Hohenbergia*, *Bauhinia*, *Meriania*, *Tecoma*, *Besleria*, *Psychotria*, *Erythrina*, *Eucalyptus*, *Spathodea* and *Calliandra*, generally at height of 2-4 m. Utilizes nectar of large garden flowers by means of holes in corollas pierced by Bananquits (*Coereba flaveola*); also inspects fresh Yellow-bellied Sapsucker (*Sphyrapicus varius*) holes in trunks. Feeds on insects in the air, and takes them also from leaves, flowers, branches or spider webs.

Breeding. Breeds all year round but chiefly from Jan to mid-May. Cup-shaped nest of fine plant fibres and cobweb, with lichen attached to outer wall, placed on thin twig 1-3 m above ground. Clutch size 2; incubation 17-19 days, by female; chick black with two dorsal rows of pale grey down; fledging period 19-24 days; young remain with female for 3-4 weeks; up to 3 broods per year. First breeding in second year.

Movements. Individuals disperse to higher altitudes after main breeding season.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species: present in Jamaica EBA. Common resident. Particularly common in Blue Mts, with densities of at least 12 pairs/km². Widespread throughout most of the island, occurring at all altitudes and in all habitat types; ready occupation of man-made habitats suggests that habitat loss is unlikely to be a problem. Trapping for wild bird trade was significant until 1960's, but has now apparently stopped.

Bibliography. Allen (1961), Anon. (1998a), Blake, C.H. (1956), Bond (1985), Danforth (1928), De Quincey (1960), Douglas & Levy (1996), Downer (1972), Downer & Sutton (1990), Evans, M.R. *et al.* (1994, 1995), Gill *et al.* (1973), Gosse (1847), Krüger *et al.* (1982), Lack (1976), Leck (1974), Lodge (1896), Raffaele *et al.* (1998), Reuther (1959), Rutgers & Norris (1972), Salmon (1972), Schuchmann (1977c, 1978, 1979g, 1980a, 1980b, 1980c, 1983b, 1990a), Schuchmann & Prinzinger (1987), Schuchmann & Schmidt-Marloh (1979a, 1979b), Schürer & Bock (1983), Spence (1978), Stattersfield *et al.* (1998), Stedman, H. (1965), Stedman, V. (1974), Stotz *et al.* (1996), Tyrrell & Tyrrell (1990), Witt (1980).

89. Black-billed Streamertail

Trochilus scitulus

French: Colibri à bec noir

German: Schwarzschnabel-Jamaikasylyphe

Spanish: Colibri Portacintas Piquinegro

Other common names: Eastern Streamertail (Hummingbird), Doctor Bird, Scissor Tail

Taxonomy. *Aithurus scitulus* Brewster and Bangs, 1901, Priestman's River, Portland Parish, Jamaica. Genus closely related to *Chlorostilbon*. Forms a superspecies with *T. polytmus*, with which formerly considered conspecific, but differs in display and voice; occasional hybridization in W John Crow Mts. Monotypic.

Distribution. Extreme E Jamaica.

Descriptive notes. Male 22-35 cm (including bill 2.2 cm, tail 16-24 cm), 5-3 g; female 10-5 cm, 4-3 g. Male very similar to that of *T. polytmus*, but slightly smaller (except for streamers), with bill black; duller green overall, less yellow tinge to underparts, less bronzy tinge to upperparts. Female very similar to that of *T. polytmus*, but bill all black.

Habitat. Wet E Jamaica from sea-level (Port Antonio) to elfin forest (John Crow Mts). Most abundant in semi-open areas like parks, banana plantations and mountain ridges. Rarely inside dense vegetation.

Food and Feeding. Habits very similar to

those of *T. polytmus*.

Breeding. Nests all year round, chiefly Feb-Jun. Cup-shaped nest of fine rootlets and fibres is more loosely built than that of *T. polytmus*, apparently an adaptation to high precipitation; often placed on thin branches sheltered by large leaves. Clutch size 2; incubation 17-20 days, by female; chick darkish, two rows of pale grey dorsal down; fledging period 17-19 days; young remain with female for 3-4 weeks; up to 2 broods per year. First breeding in second year.

Movements. Insufficiently known, densities increase in Aug at higher altitudes around 800-1000 m.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species: present in Jamaica EBA. Common resident, but less numerous than *T. polytmus*. Particularly common around Port Antonio and Bath, with densities of at least 3-6 pairs/km². Ready occupation of man-made habitats means that habitat loss is unlikely to be a threat, but range tiny.

Bibliography. Anon. (1998a), Bond (1985), Danforth (1928), Downer & Sutton (1990), Gill *et al.* (1973), Lack (1976), Lodge (1896), Raffaele *et al.* (1998), Schuchmann (1977d, 1978, 1979g, 1980a, 1980b, 1980c, 1990a), Schuchmann & Jakob (1981a), Schuchmann & Schmidt-Marloh (1979a, 1979b), Spence (1978), Stattersfield *et al.* (1998), Tyrrell & Tyrrell (1990).

Genus *CHLOROSTILBON* Gould, 1853

90. Blue-chinned Sapphire

Chlorostilbon notatus

French: Colibri à menton bleu

Spanish: Esmeralda Gorgiazul

German: Blaukinn-Smaragdkolibri

Other common names: Audebert's Hummingbird

Taxonomy. *Trochilus notatus* Reich, 1793, Cayenne.

Formerly placed in monospecific genus *Chlorestes*, but morphology and bioacoustics indicate that merging into *Chlorostilbon* is more appropriate. Author and year of scientific description of species have consistently been misquoted. Racial variation complex and possibly not constant; intermediate populations exist. Birds of Brazil S of Amazon formerly awarded race *cyanogenys*. Two highly doubtful forms known only from trade skins (one and two respectively) from Bahia: "*C. subcaeruleus*" is probably a hyperchromatic aberration of present species; "*C. hypocyaneus*" may be a mutant of present species, or hybrid of present species with *Hylocharis cyanus*, or possibly even a valid species. Also, "*Eucephala scapulata*", known from single specimen from French Guiana, is probably a hybrid of present species with *Thalurania furcata*. Three subspecies currently recognized.

Subspecies and Distribution.

C. n. notatus (Reich, 1793) - NE Colombia through N & E Venezuela, Trinidad and Tobago, and the Guianas to E Brazil (Pará to Bahia).

C. n. puruensis Riley, 1913 - NW Brazil (N of Amazon, E to mouths of R Trombetas and R Negro) to SE Colombia and NE Peru (upper R Ucayali).

C. n. obsoletus (Zimmer, 1950) - NE Peru on lower R Ucayali near mouth of R Napo, and W probably to mouth of R Huallaga.

Descriptive notes. Male 8-9 cm, female 7-8 cm; 3-4 g. Male has short straight bill, red tipped black; upperparts shining bronzy-green; chin iridescent blue, underparts iridescent green, variably tinged golden or bluish; tail forked, steel blue. Female upperparts and bill similar to male; underparts white with glittering discs on throat and breast, becoming merely shiny on rest of underparts, undertail-coverts green; tail steel blue. Immature similar to adult female. Male of race *puruensis* has a weak chin spot, less extensive and less defined; *obsoletus* has greener underparts, lacks chin spot.

Habitat. Common in savanna, plantations, town gardens, fields, hedgerows and edges of deciduous woodlands, from sea-level to 500 m. Forages at low to medium heights, 1-6 m.

Food and Feeding. Feeds usually on nectar of flowering garden plants such as *Russelia*, *Salvia*, *Hibiscus*, as well as *Erythrina*, *Heliconia* and coffee bushes. Takes spiders, insects and insect honeydew; insects are caught in the air by hawking. Males establish feeding territories which are aggressively defended against intruders.

Breeding. Aug-Nov. Cup-shaped nest placed on thin branch of small tree or exposed root c. 1 m above ground. Nest materials are fine fibres of plants, leaves and strips of bark. Cobweb is woven in for greater stability, interior is lined with soft material such as downy seeds or seed fibres, outside ornamented with lichen, pieces of leaf, and twigs. Clutch size 2; incubation 14-16 days, by female; chick darkish grey with two dorsal rows of grey down; fledging at 20-22 days. First breeding in second year.

Movements. Sedentary.

Status and Conservation. Not globally threatened. CITES II. Common throughout range. Readily takes to man-made habitats like plantations and parks. Abundant in forested lowland areas of Trinidad, with density of at least 3-4 pairs/km². Regularly recorded in Henri Pittier National Park (Venezuela), Asa Wright Nature Centre (Trinidad), Kanuku Mts (S Guyana) and around Mana (NW French Guiana).

Bibliography. Bangs & Penard (1918), Berlioz (1932b, 1938, 1965), Butler (1958), de Carvalho (1958), Cotton (1998a), French (1991), Grantsau (1988), Gyldenstolpe (1951), Haverschmidt & Mees (1994), Hayes & Samad (1998), Herklots (1961), Hilty & Brown (1986), Junge & Mees (1958), Meyer de Schauensee & Phelps (1978), Morrison (1962), Parker *et al.* (1982), Riley (1915), Ruschi (1950b, 1957b, 1962f, 1964d, 1981-1982, 1986), Rutgers & Norris (1972), Sick (1993, 1997), Snyder (1966), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Tostain *et al.* (1992), Walters (1996), Willis (1992), Zimmer (1950d).

91. Blue-tailed Emerald

Chlorostilbon mellisugus

French: Émeraude orvert **German:** Blauschwanz-Smaragdkolibri **Spanish:** Esmeralda Coliazul
Other common names: Golden-crowned Emerald (*auriceps*); Cozumel Emerald (*forficatus*); Fork-tailed/Canivet's Emerald (*canivetii*); Salvin's Emerald (*salvini*); Garden/Allied Emerald (*assimilis*); West Andean Emerald (*melanorhynchus*); Red-billed Emerald (*gibsoni*)

Taxonomy. *Trochilus mellisugus* Linnaeus, 1758, Cayenne.

Forms superspecies with *C. olivaresi*, which may be merely a race of present species (see page 474). Taxonomy highly complex and uncertain: present species has been considered to comprise from two to as many as eight different species by some authors, mainly on basis of differences in bill colour, together with shape of tail and overall coloration. The different forms sometimes raised to full species are: *auriceps*; *forficatus*; *canivetii*; *salvini* (including *osberti*); *assimilis*; *melanorhynchus* (including *pumilus*); and *gibsoni* (including *chrysogaster* and *nitens*). Alternatively, on the basis of bill colour, the five northernmost races have been lumped under *canivetii* as one species, *assimilis* recognized as a separate species, *gibsoni* (including *chrysogaster* and *nitens*) as a third species, and the remaining eight southern races retained as present species; this arrangement has at times been varied by some with the lumping of *assimilis* within the *mellisugus* group, or a transfer of *melanorhynchus* (including *pumilus*) to the *gibsoni* group. However, length of tail and depth of tail-fork appear to decrease consistently from N to S, while red-billed forms appear in both N and S groups; also, the different forms replace each other geographically, with ranges consistently meeting, and until further study produces convincing evidence to the contrary it may be best to treat them all as conspecific. Several of the presently accepted races may be invalid; further study required, especially in zones of possible contact. Proposed race *nanus* of upper and middle Orinoco Valley, at one stage placed in *canivetii* group, may be best considered a synonym of *caribaeus*. Form *napensis* (= *vitticeps*) of Napo Valley (E Ecuador) indistinguishable from *phoeopygus*. Species formerly known as *C. prasinus*, when name *mellisugus* was erroneously thought to apply to *Saucerottia saucerrottei braccata*. Seventeen subspecies currently recognized.

Subspecies and Distribution.

C. m. auriceps (Gould, 1852) - W & C Mexico (S Sinaloa and SW Durango to Guerrero and Oaxaca).
C. m. forficatus Ridgway, 1885 - islands of Holbox, Mujeres and Cozumel, off coast of Yucatán.
C. m. canivetii (Lesson, 1832) - SE Mexico (S Tamaulipas to Yucatán), Belize, N Guatemala and Bay Is (Honduras).
C. m. osberti Gould, 1860 - SE Mexico (extreme SE Chiapas), W & C Guatemala and El Salvador to Honduras and Nicaragua.
C. m. salvini Cabanis & Heine, 1860 - Costa Rica, in highlands of Pacific coast (except regions occupied by next race).
C. m. assimilis Lawrence, 1861 - SW Costa Rica (Térraba Valley and Dota Mts) and arid Pacific coast of Panama (including Pearl Is).
C. m. pumilus Gould, 1872 - arid and semi-arid tropical and subtropical zones of W Colombia and W Ecuador.
C. m. melanorhynchus Gould, 1860 - upper subtropical W Colombia into temperate zone in W & C Andes of Ecuador.

C. m. gibsoni (Fraser, 1840) - upper Magdalena Valley (C Colombia).

C. m. chrysogaster (Bourcier, 1843) - N Colombia from Cartagena to Santa Marta.

C. m. nitens Lawrence, 1861 - NE Colombia and NW Venezuela (W & N of Andes of Mérida).

C. m. caribaeus Lawrence, 1871 - islands of Curaçao, Aruba, Bonaire, Trinidad and Margarita, and NE Venezuela.

C. m. duidae Zimmer & Phelps, 1952 - Mt Duida (S Venezuela).

C. m. subfurcatus Berlepsch, 1887 - E & S Venezuela, Guyana and the Rio Branco region of NW Brazil.

C. m. mellisugus (Linnaeus, 1758) - Surinam, French Guiana, lower Amazon Valley of Brazil.

C. m. phoeopygus (Tschudi, 1844) - upper Amazon and its eastern tributaries in Colombia, Ecuador, Peru and Bolivia.

C. m. peruanus Gould, 1861 - Peru and E Bolivia.

Descriptive notes. Male 7.5-8.5 cm, female 6.5-7.5 cm; 3-3.5 g. Male has short, straight bill, colour varying with race; forehead and crown iridescent golden green, upperparts shining bronzy-green; underparts glittering emerald green, breast more iridescent than the rest of underparts; tail steel blue, extent of fork varying with race. Female has bill black; bronzy-green on forehead and crown, blackish band across ear-coverts bordered above by pale grey spot behind the eye, rest of upperparts metallic grass green; underparts pale grey; tail mainly blue-black, tipped with whitish-grey. Immature resembles adult female. Races differ mainly in colour of bill, length of tail, depth of tail fork, and overall coloration: varying amounts of red on bill within two groups, northernmost five races and southern *gibsoni*, *chrysogaster* and *nitens*, all other races with totally black bill; length of tail and depth of tail-fork appear to decrease consistently from N to S, being greatest in northern *auriceps* and *forficatus* and shortest in *mellisugus* group; overall coloration ranges from yellowish-orange (*duidae*, *auriceps*) to various shades of green, with more or less marked bluish throat patch; females of some races show more white in tail, and some (e.g. *auriceps*, *canivetii*) have partially red bill.

Habitat. From tropical to temperate zone, mainly between 1000 and 2600 m, but locally to sea-level and recorded up to 3050 m in Loja (S Ecuador). Common in xerophytic habitats like savanna, *cerrado*, cultivated areas, plantations, town gardens, fields, hedgerows and edges of deciduous woodlands. Forages from low to medium heights, c. 1-6 m, occasionally in canopy when orange trees are in flower.

Food and Feeding. Usually feeds low down on nectar of flowering *Hibiscus* and *Cannaceae*, sometimes taking nectar by piercing the petals of *Laminaceae*; further food plants are *Opuntia wentiana*, *Odontoglossum biconiense*, *Epidendrum brassavolae*, *Tamarindus indica*, *Beureria succulenta*, *Acacia tortuosa*, *Cordia sebestena*, *Hibiscus rosa-sinensis*, *Poinciana regia*, *Leonotis nepetifolia* and *Bougainvillea spectabilis*. Takes honeydew from *Diaspididae* found in *bracaatinga* trees (*Mimosa bracaatinga*). Insects are caught in the air by hawking. Trap-liner.

Breeding. Jan-Jun in W and C Andes. Cup-shaped nest is placed in dense, low, second growth woodland c. 0.8 m above ground, fixed on a sloping branch. The lining is of downy plant material. Clutch size 2; incubation 13-14 days, by female; chick darkish grey with two dorsal rows of dark down; fledging at c. 20 days. First breeding in second year.

Movements. Sedentary, seasonal altitudinal dispersal after breeding.

Status and Conservation. Not globally threatened. CITES II. Readily accepts man-made habitat. Generally common throughout much of its extensive range, e.g. in upper Amazonia. The most abundant and widespread hummingbird in Honduras. Race *forficatus* sometimes considered full species, and then classified as restricted-range species: present in Cozumel Island EBA.

Bibliography. Arizmendi & Ornelas (1990), Belcher & Smoother (1936), Berg (1994), Binford (1989), Blake (1953), Bloch *et al.* (1991), Bond (1936), Bond & Meyer de Schauensee (1943), del Campo (1963), Cotton (1998a), Craigie (1928), Davis (1960), Des Granges & Grant (1980), Echeverri (1986), Egg (1969), Eisenmann (1955), Elgar (1980), Feinsinger (1976, 1980), Feinsinger & Colwell (1978), French (1991), Fjeldsá & Krabbe (1990), Fogden (1993), Friedmann (1948), Friedmann *et al.* (1950), Grantsau (1988), Griscom (1932a), Gyldenstolpe (1945a, 1945b), Hartert (1922), Haverschmidt & Mees (1994), Hilty (1985), Hilty & Brown (1986), Howell (1993a), Howell & Webb (1995a), Hummelinck (1957), Johnsgard (1997), Land (1970), Lowery & Dalquest (1951), Lynch (1992), Meyer de Schauensee (1964), Meyer de Schauensee & Phelps (1978), Monroe (1968), Oberholser (1902), Olivares (1969), Olrog (1963c), Parkes (1970), Paynter (1955), Phelps & Phelps (1958), Pinto (1978), Pople *et al.* (1997), Rand & T aylor (1954), Ridgely & Gwynne (1989), Ridgway (1911), Rowley (1962, 1966), Ruschi (1960, 1981-1982, 1982a, 1986), Russell (1964), Schaldach (1963), Schemske (1980), Seutin *et al.* (1997), Sick (1993, 1997), Slud (1964), Smith & Paynter (1963), Snow & Snow (1980), Snyder (1966), Stattersfield *et al.* (1998), Steinbacher (1952), Stiles (1980, 1996), Stiles & Skutch (1989), Stotz *et al.* (1996), Sutton (1898), Thomas (1994), Tiebout (1991a, 1991b, 1993, 1996), Todd (1942), Tostain *et al.* (1992), Underwood (1896), Voous (1983), Wagner (1957b), Wetmore (1939, 1968a), Williams & Tobias (1994), Wolf (1964), Zimmer (1950e).

92. Chiribiquete Emerald

Chlorostilbon olivaresi

French: Émeraude d'Olivares

Spanish: Esmeralda del Chiribiquete

German: Chiribiquete-Smaragdkolibri

Taxonomy. *Chlorostilbon olivaresi* Stiles, 1996, Sierra de Chiribiquete, south-east Colombia. Forms superspecies with *C. mellisugus*, and may be conspecific (see page 474). Monotypic.

Distribution. Sierra de Chiribiquete, in Guaviare and Caquetá (SE Colombia).

Descriptive notes. 8.5-9 cm; male 3-8 g, female 3-6 g. Much larger and longer-billed than *C. mellisugus*. Male has upperparts metallic green, sides of head and neck with strong golden green reflections in fresh plumage; a small greyish-white postocular spot; uppertail-coverts more bluish-green, tail dark steel blue, with shallow fork; throat and upper breast glittering blue-green, passing to bright metallic green on belly and vent. Female metallic bronze-green above, pale grey below; a white postocular stripe above dusky facial area and auriculars; most of tail bluish-green, the lateral rectrices with grey bases, dark blue

subterminal band, white tips. Upper mandible of male black, lower red with black tip; lower mandible of female black, tinged red at base; feet black. Immature resembles adult female but duller, more bronzy above and duller, darker grey below; tail of young male mostly blue-black, outer tail feather tipped dull grey.

Habitat. Open scrub and savanna-like vegetation on flat mesas of middle and upper regions of the Sierra de Chiribiquete; some penetration of adjacent forests where soil is deeper, but not of the taller forests of the surrounding lowlands.

Food and Feeding. Visits scattered flowers of *Decagonocarpus cornutus* in open areas, also blooms of other shrubs or small trees in adjacent wooded areas; not known to defend feeding territories. Sallies to capture small flying insects, mostly at gaps in the vegetation, and gleans tiny insects (including thrips) from foliage and flowers of *Bonnetia* shrubs.

Breeding. Probable season Dec-May, during dry season. Nest undescribed; no further information.

Movements. Sedentary so far as known.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species; occurs in Sierra de Chiribiquete Secondary Area. The commonest hummingbird in its unusual, insular habitat, most of which is (nominally) protected in Chiribiquete National Park; since the habitat is unavailable to agriculture or other destructive uses there would appear to be no imminent threat to the species.

Bibliography. Díaz, Stiles & Tellería (1996), Stattersfield *et al.* (1998), Stiles (1996), Stiles *et al.* (1995).

93. Glittering-bellied Emerald

Chlorostilbon aureoventris

French: Émeraude splendide

Spanish: Esmeralda Ventridorada

German: Goldbauch-Smaragdkolibri

Other common names: Pucheran's Emerald (*pucherani*)

Taxonomy. *Ornismya aureo-ventris* d'Orbigny and Lafresnaye, 1838, Rio de Janeiro.

Name "*C. lucidus*", sometimes used for present species, is probably unidentifiable, but, if a synonym, must be regarded as a forgotten name. Race *pucherani* has been considered by some to be approaching the species threshold. Race *igneus* doubtfully separable from nominate. "*H. pyropygia*" is probably a hybrid of present species and *Hylocharis cyanus*. Four subspecies currently recognized.

Subspecies and Distribution.

C. a. pucherani (Bourcier & Mulsant, 1848) - E Brazil (Maranhão and Ceará S to Paraná).

C. a. aureoventris (d'Orbigny & Lafresnaye, 1838) - Bolivia, Paraguay and WC Brazil (Mato Grosso).

C. a. igneus Gould, 1861 - NW Argentina (Jujuy and Chaco S to Mendoza and San Luis).

C. a. berlepschi Pinto, 1938 - S Brazil (Rio Grande do Sul) and Uruguay to NE Argentina (Misiones, Entre Rios, Corrientes, Buenos Aires).

Descriptive notes. Male 9.5-10.5 cm, female 7.5-8.5 cm; 3.5-4.5 g. Male has short, straight bill, upper and lower mandibles red, tipped black; crown and forehead dull bronzy-green, upperparts slightly gold-green, uppertail-coverts bronzy green; belly iridescent bronze to bronzy-green, changing to blue-green on throat and upper breast, underparts in general more iridescent than upperparts; tail slightly forked, dark steel blue. Female has bill like male but the black extends to the middle of the bill; forehead, crown and upperparts slightly golden green, greyish-white streak behind the eye; uppertail-coverts grass green; underparts whit-

ish changing to pale brownish-grey on breast and belly; tail slightly forked, rectrices basally green and distally blue, outer four rectrices all steel blue with pale grey V-shaped tips. Immature resembles adult female. Race *berlepschi* differs from nominate in colour of upperparts and underparts (purer green and not gold-green); *igneus* has belly liberally sprinkled with glittering orange-gold; *pucherani* slightly smaller than nominate.

Habitat. Widespread in semi-arid to moderately humid scrub, savanna, grassland, and forest margin habitats in tropical and subtropical zones of the Amazon area to foot of Bolivian Andes; frequent in parks and gardens, from sea-level to 3500 m, commonest at 500-2500 m. Forages at 4-12 m above ground.

Food and Feeding. Feeds on nectar of flowering *Tabebuia*, *Eucalyptus* and *Jacaranda acutifolia* by piercing the petal bases; also on fruits of *Ficus diabolica*. Its preferred flowers are *Lantana*

camara, *Duranta arborea*, *Citrus sinensis*, *Abutilon striatus* and *Eucalyptus robusta*. Feeds by trap-lining. Takes insect honeydew of Coccidae at *Mimosa bruceana*. Insects are caught in the air by hawking.

Breeding. Aug-Nov. Cup-shaped nest placed on thin branch of small tree or exposed root c. 1 m above ground; nest materials are fine plant fibres, pieces of leaf and strips of bark; cobweb is woven in for greater stability; interior lined with soft material such as downy seeds or seed fibres of *Typha domingensis*, Gramineae, Bromeliaceae, *Chorisia* and *Asclepias curassavica*; outside decorated with lichen, pieces of leaf, cortex and twigs, camouflaging the nest. Clutch size 2; incubation c. 14 days, by female; chick darkish grey with two dorsal rows of darkish down; fledging at 20-22 days. First breeding in second year.

Movements. Sedentary.

Status and Conservation. Not globally threatened. CITES II. Common throughout much of its extensive range. Readily accepts man-made habitats such as gardens, parks and plantations. Within its range in Argentina, is the most commonly seen hummingbird species. Occurs in a number of protected areas throughout range, such as Serra dos Órgãos and Chapada dos Guimarães National Parks (Brazil) and Costanera Sur Ecological Reserve (Argentina).

Bibliography. Belton (1984, 1994), Berlioz (1938, 1949b), Bond & Meyer de Schauensee (1943), Brooks *et al.* (1993), Canevari *et al.* (1991), Contreras (1987), Contreras *et al.* (1990), Dubs (1992), Eisenraut (1935), Fjeldså & Krabbe (1990), Fraga (1984a), Grantsau (1988), Hayes (1995), Hellmayr (1929), Hünig (1999), Klimaitis & Moschione (1987), Kühme (1987), Lowen, Bartrina, Clay & Tobias (1996), Marelli (1938), Narosky & di Giacomo (1993), Navas (1982), Norez *et al.* (1983), Oniki (1996), Oniki & Antunes (1998), de la Peña (1994, 1995), Pereyra (1931), Pinto (1978), Reichholf & Reichholf (1973), do Rosário (1996), Ruschi (1960, 1973d, 1981-1982, 1986), Rutgers & Norris (1972), Saibene *et al.* (1996), Short (1975), Sick (1993, 1997), Stotz *et al.* (1996), Tobias *et al.* (1993), Todd (1938, 1942), Vigil (1973), Wetmore (1926).

94. Cuban Emerald

Chlorostilbon ricordii

French: Émeraude de Ricord

German: Kubasmaragdkolibri

Spanish: Esmeralda Zunzún

Taxonomy. *Ornismya Ricordii* Gervais, 1835, Santiago, Cuba.

Forms a superspecies with *C. swainsonii* and *C. maugaeus*, and these three formerly separated in genus *Riccordia*. In past, considered to include Braze's Emerald (*C. brazei*) as an extinct race, but this form now considered most likely a separate species (see page 533). Monotypic.

Distribution. Cuba (including Cayo Coco, Cayo Largo and nearby cays) and I of Pines, and Bahamas (Grand Bahama, Great Abaco, Andros, Green Cay); casual in rest of Bahamas.

Descriptive notes. Male 10.5-11.5 cm, female 9.5-10.5 cm; 3-4.5 g. Male has slightly decurved, short bill, upper mandible dull black, lower red, tipped black; forehead dull brownish-green, small postocular spot greyish-white, upperparts dark shining green, tinged with bronze, darker and duller on crown; underparts iridescent metallic green, sometimes with a few small spots or greyish streaks on the lateral feathers; undertail-coverts white, sometimes with greyish streaks; tail deeply forked, the four central rectrices dark metallic bronze or greenish-bronze, next pair similar but with inner webs dark brown. Female has upperparts similar to male, longer postocular spot; underparts brownish-grey, sides from neck to flank metallic green, undertail-covert tufts white; tail less forked than male.

Habitat. Occupies a variety of lowland habitats up to 200 m, humid and arid open forest. On Grand Bahama, common in bushy undergrowth of open pine woods, and coastal scrub forest, gardens, parks and plantations. Forages at low to medium height, 1-6 m.

Food and Feeding. Nectar of flowering shrubs and trees, including *Barleria cristata* and *Tabebuia rosae*. Insects are caught in the air by hawking, and occasionally gleaned from spider webs.

Breeding. All year round. Gregarious nesting recorded on Cuba, with 6 nests located, averaging c. 30 cm apart, in cactus-like *Euphorbia nivulia*; no aggression apparent. Cup-shaped nest is loosely woven, composed of moss and silky plant fibres, held together with long trailing tendrils of bark and spider web on outside wall, often flecked with pieces of bark and lichens; nest often found in forks of young branches of coffee and vines 1-3 m above ground; old nest-sites regularly used again. Clutch size 2; incubation 15-16 days, by female; chick dusky coloured with two dorsal rows of buffy white down; fledging period 19-22 days. First breeding in second year.

Movements. Sedentary, some local altitudinal dispersal. Vagrant to Florida, USA.

Status and Conservation. Not globally threatened. CITES II. Readily inhabits man-made habitat. Generally common throughout much of its extensive range. On Andros (Bahamas), density of at least 3-4 pairs/km² recorded.

Bibliography. Alayón (1980), Allen (1961), Anon. (1998a), Barbour (1943), Behnke-Pedersen (1972), Bond (1956a, 1985), Brudenell-Bruce (1975), Buden (1987b), Chapman (1902), DeBenedictis (1991), Emlen (1977), García & Rojas (1997), Gundlach (1876), Hernández & Tadeo (1997), Johnsgard (1997), Kale (1977), Lack (1976), Paterson (1972a), Raffaele *et al.* (1998), Regalado (1998), Ridgway (1911), Robertson & Woolfenden (1992), Rutgers & Norris (1972), Stimson (1944), Stotz *et al.* (1996), Terres (1982), Todd (1942), Tyrrell & Tyrrell (1990), Vaune (1957).

95. Hispaniolan Emerald

Chlorostilbon swainsonii

French: Émeraude d'Hispaniola

Spanish: Esmeralda de la Española

German: Hispaniolansmaragdkolibri

Taxonomy. *Ornismya Swainsonii* Lesson, 1829, Brazil; error = Hispaniola.

Forms a superspecies with *C. ricordii* and *C. maugaeus*, and these three formerly separated in genus *Riccordia*. Monotypic.

Distribution. Hispaniola; erroneously recorded from Gonâve.

Descriptive notes. Male 9.5-10.5 cm, female 8.5-9.5 cm; 2.5-5 g. Male has maxilla black, mandible red, distal third slightly decurved; forehead, crown, and cheeks dull dark brown, rest of upperparts

and flanks dark green with some bronze, uppertail-coverts dark green; underparts darker green than upperparts, throat iridescent green with large blackish patch on centre of breast, undertail-coverts dark green; tail deeply forked, dark brown. Female has bill more decurved than male; forehead, crown and cheeks dull dark brown, rest of upperparts and flanks dark green tinged with bronze, uppertail-coverts dark green; underparts grey, darker on belly and undertail-coverts; outer rectrix basally greyish, with a broad dark brown subterminal band, tipped white, next rectrix basally dark grass green, shading into black,

the remaining rectrices green. Immature resembles adult female.

Habitat. Dense montane rainforest, forest edges and scrub, at 500–2500 m, occasionally to sea-level. Forages in low to high strata at 3–18 m.

Food and Feeding. Feeds on nectar of flowering *Heliconia bihai*, *Rhytidophyllum auriculatum*, *Caesalpinia pulcherrima*, *Aechmea* and *Hibiscus*. Trap-liner; hawks for insects in the air.

Breeding. Feb–Jun, but with irregular nesting throughout the year. Large cup-shaped nest of moss and fern fibres, externally decorated with lichen, built in shrubs 0.5–1 m above ground. Clutch size 2; incubation 15–16 days, by female; chick dark grey with two rows of darkish dorsal down; fledging at 20–22 days. First breeding in second year.

Movements. Sedentary, with occasional altitudinal wandering.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species: present in Hispaniola EBA. Most of its very small range is under threat of deforestation, especially Haitian part of Hispaniola. Readily accepts man-made habitats as long as patches of forest remain.

Bibliography. Allen (1961), Anon. (1998a), Behnke-Pedersen (1972), Bond (1928a, 1956a, 1985), Curzon (1998), Dod (1987, 1992), Lack (1976), Raffaele *et al.* (1998), Ridgway (1911), Rimmer *et al.* (1998), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Todd (1942), Tyrrell & Tyrrell (1990), Wetmore & Swales (1931).

96. Puerto Rican Emerald

Chlorostilbon maugaeus

French: Émeraude de Porto Rico

Spanish: Esmeralda Portorriqueña

German: Puerto-Rico-Smaragd Kolibri

Other common names: Antillean Emerald

Taxonomy. *Trochilus Maugaeus* Audebert and Vieillot, 1801, Puerto Rico.

Forms a superspecies with *C. ricardii* and *C. swainsonii*, and these three formerly separated in genus *Riccordia*. Monotypic.

Distribution. Puerto Rico.

Descriptive notes. Male 8.5–9.5 cm, female 7.5–8.5 cm; 3.4–3.8 g. Male has short straight bill, upper mandible dull black, lower red, tipped black; forehead and crown iridescent green, dark shining metallic green upperparts and uppertail-coverts; throat iridescent bluish-green, rest of underparts and undertail-coverts shining green; tail forked, shining steely blue. Female has bill black; forehead and crown dull dark green; upperparts and uppertail-coverts shining grass green; throat and breast are light grey becoming darker on belly; tail less forked, outer rectrices basally pale white, becoming brown in centre and tipped with a large white

spot, second outermost rectrices shining greenish-white at base changing to steel blue, tipped with white spot, the next innermost two are green from base to centre, rest of feather dull brown, the inner rectrices are shining green. Immature resembles adult female.

Habitat. Coastal mangroves to forested mountain summits. Open forest, woodland and coffee plantations, from sea-level to 800 m. Forages in low to medium strata, c. 1–6 m.

Food and Feeding. Feeds on nectar of a wide spectrum of flowers, including *Hohenbergia portoricensis*, *Vriesea sintenisii*, *Dilomilis montana*, *Epidendrum* sp., *Hedychium coronarium*, *Renealmia antillarum*, *Justicia martinsoniana*, *Ruellia coccinea*, *Sanchezia nobilis*, *Thumbbergia erecta*, *Spathodea campanulata*, *Tabebuia haemantha*, *T. rigida*, *T. schumanniana*, *Clusia krugiana*, *C. minor*, *Erythrina berterouana*, *Neorudolphia volubilis* and *Sabinea punicea*. Trap-liner. Arthropod diet includes flies, Homoptera, Hymenoptera and small spiders, gleaned from branches and leaves of trees.

Breeding. Feb–May, but irregular nesting all year round. The nest, a compact structure in the form of a small cup, is composed of dry plant fibres, such as tree fern scales, lined with wild cotton and other soft plant material, externally decorated with lichen. It is generally built in either low or medium-sized plants and trees. Clutch size 2; incubation 14–16 days, by female; chick darkish grey with two rows of dark down on the upperside; fledging at 20–22 days. First breeding in second year.

Movements. Sedentary.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species: present in Puerto Rico and the Virgin Islands EBA. Readily accepts man-made habitats like plantations, gardens and parks. Generally common throughout Puerto Rico.

Bibliography. Allen (1961), Anon. (1998a), Behnke-Pedersen (1972), Biaggi (1983), Bond (1956a, 1985), Kodric-Brown *et al.* (1984), Lack (1976), Orelas (1994), Otero (1998), Raffaele (1989), Raffaele *et al.* (1998), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Todd (1942), Tyrrell & Tyrrell (1990), Wetmore (1916, 1927).

97. Coppery Emerald

Chlorostilbon russatus

French: Émeraude cuivrée

Spanish: Esmeralda Bronceada

German: Bronzeschwanz-Smaragd Kolibri

Taxonomy. *Panychlora russata* Salvin and Godman, 1881, Manaua, San Sebastián and San José, Santa Marta, Colombia.

Monotypic.

Distribution. NE Colombia (lower Magdalena Valley and Santa Marta region) and NW Venezuela.

Descriptive notes. Male 8–8.5 cm, female 7–7.5 cm; 3.2–3.6 g. A very distinctive species, readily distinguished from its congeners by rich coppery gloss of the tail-coverts and wing-coverts in both sexes. Male has short, straight, black bill; forehead, crown and upperparts shining golden green, uppertail-coverts coppery green; underparts glittering golden green; tail slightly forked, golden coppery. Female has bill like male; forehead, crown and uppertail-coverts coppery green; underparts smokey grey with some green on flanks; tail slightly forked, greenish-coppery, all but central tail feathers with coppery purple subterminal band, tipped pale. Immature resembles adult female but with buffy fringes on head feathers.

Habitat. Scrub, forest edge and cultivated areas such as plantations and farms; from sea-level to 2600 m, commonest at 500–1700 m. Forages at low to moderate heights, around 4–12 m.

Food and Feeding. Feeds on nectar of Leguminosaceae, Rubiaceae, Heliconiaceae and Gesneriaceae. Trap-liner. Insects are caught in the air by hawking, occasionally gleaned from plant surfaces.

Breeding. May–Jun. Cup-shaped nest is placed around 0.8 m above ground, fixed on a sloping branch; lining is of downy plant material. Clutch size 2; incubation 15–16 days, by female; chick darkish grey with two dorsal rows of dark down; fledging at c. 20 days. First breeding in second year.

Movements. Sedentary, with seasonal local altitudinal dispersal, especially after reproduction.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species: present in Santa Marta Mountains EBA and Colombian East Andes EBA. A species with patchy distribution, generally uncommon to locally common. Quickly takes to man-made habitats like plantations and parks with scattered trees.

Bibliography. Avelledo & Pons (1952), Berlepsch (1888), Boucard (1892b), Chapman (1917), Fjeldså & Krabbe (1990), Hilty & Brown (1986), Meyer de Schauensee (1949, 1964, 1982), Meyer de Schauensee & Phelps (1978), Oberholser (1902), Olivares (1969), Olrog (1968), Phelps & Phelps (1958), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Todd (1942), Todd & Carriker (1922).

98. Narrow-tailed Emerald

Chlorostilbon stenurus

French: Émeraude à queue étroite

Spanish: Esmeralda Colifina

German: Schmalschwanz-Smaragd Kolibri

Taxonomy. *Panychlora stenura* Cabanis and Heine, 1860, Mérida.

Possibly forms a superspecies with *C. alice* and *C. poortmani*. Race *ignotus* sometimes considered synonymous with *C. alice*, or treated as a hybrid. Birds of Colombia and Ecuador have been separated as race *acuticaudus*, but doubtfully valid. Two subspecies recognized.

Subspecies and Distribution.

C. s. ignotus Todd, 1942 - NW Venezuela, from coastal range S to highlands of extreme SE Lara. *C. s. stenurus* (Cabanis & Heine, 1860) - NW Venezuela (Trujillo, Mérida, Táchira) and NE Colombia (Norte de Santander possibly S to W Meta); NE Ecuador (Baeza).

Descriptive notes. Male 8.5–9 cm, female 7.5–8 cm; 3.2–3.6 g. Male has short, straight, black bill; forehead and crown shining green, upperparts including uppertail-coverts shining grass green; underparts and flanks iridescent green; tail forked, dark green, outer two rectrices very small, stiletto-like, remainder normally shaped. Female has bill slightly decurved; small white streak above and behind eye, and small brown bristles at basal part of bill; crown dull dark green with some bronze, the remaining upperparts and uppertail-coverts dark green; brownish chin, underparts pale white, throat lighter than belly; tail slightly

forked, outer two rectrices grey at the base, becoming dark blue with a broad white V-shaped tip, the next innermost are metallic green at the base, shading into brown with a small white V-shaped tip, central rectrices metallic bluish-green. Immature resembles adult female. Race *ignotus* is smaller, more yellowish-green above, and has duller, darker green tail.

Habitat. Humid forest, low scrub, second growth, at 1000–3000 m. Forages in low to mid-strata at 0.6–4 m.

Food and Feeding. Feeds in rather open areas on nectar of scattered low flowers with horizontal or upright corollas, like Ericaceae, Gesneriaceae, Rubiaceae, Heliconiaceae, or *Inga*. Trap-liner. Insects are caught in the air by hawking.

Breeding. Sept–Nov. Nest is cup-shaped, built of moss and decorated externally with lichen; in shrubs and lower parts of trees, 1–2 m above the ground. Clutch size 2; incubation 15–16 days, by female; chick darkish grey with two dorsal rows of dark down; fledging at c. 20 days. First breeding in second year.

Movements. Sedentary, with local altitudinal dispersal.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species: present in Cordillera de Mérida EBA and Colombian East Andes EBA. Common throughout range: Readily accepts man-made habitats. Particularly abundant above city of Mérida.

Bibliography. Behnke-Pedersen (1972), Chapman (1926), Fjeldså & Krabbe (1990), Hilty & Brown (1986), Meyer de Schauensee (1982), Meyer de Schauensee & Phelps (1978), Oberholser (1902), Olrog (1968), Phelps & Phelps (1958), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Todd (1942).

99. Green-tailed Emerald

Chlorostilbon alice

French: Émeraude alicé

German: Grünschwanz-Smaragd Kolibri

Spanish: Esmeralda Coliverde

Taxonomy. *Trochilus Alice* Bourcier and Mulsant, 1848, Caracas.

Possibly forms a superspecies with *C. stenurus* and *C. poortmani*. *C. stenurus ignotus* has been considered synonymous with present species. Probably includes *C. micans*, with all of plumage rich reddish-golden, known only from type specimen of unknown origin. "*Ptychoptera iolaima*",

known from a specimen taken at Ypanema, São Paulo (Brazil), is probably a hybrid between present species and *C. poortmani*. Monotypic.

Distribution. Mountainous regions of N Venezuela, from Falcón (Sierra de San Luis) S to Lara and Trujillo, and E to Sucre and N Monagas.

Descriptive notes. Male 7.5-8.5 cm, female 6.5-7.5 cm; 3-4 g. Male has short, straight, black bill; forehead and crown shining dark green, upperparts, wing-coverts and tail-coverts bronzy-green; underparts including undertail-coverts grass green; tail slightly forked, glittery bronzy-green. Female similar to male; underparts pale greyish, undertail-coverts dark grey; tail slightly forked, central rectrices green, rest green at base, becoming subterminally black, tipped greyish. Immature resembles adult female with buffy fringes on head feathers.

Habitat. Edges of rainforest and cloudforest;

also second growth and plantations; rarely seen in dense forest. Prefers wide and open areas and roadsides, at 700-1800 m. Forages in low to mid-strata at 1-6 m.

Food and Feeding. Feeds on nectar of various flowering shrubs and trees, including Leguminosaceae, Rubiaceae, Gesneriaceae and Ericaceae. Males occupy feeding territories at rich nectar sources. Trap-liner. Insects are caught in the air by hawking.

Breeding. Jan-Mar. Cup-shaped nest is built in shrubs and low trees, c. 1 m above ground, saddled on thin branches. Nest materials are fine plant fibres, pieces of leaves and strips of bark, interior lined with soft downy seeds or seed fibres, externally decorated with pieces of leaves and twigs. Clutch size 2; incubation 14 days, by female; chick darkish grey with two dorsal rows of darkish down; fledging at 20-22 days. First breeding in second year.

Movements. Sedentary.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species; present in Caripe-Paria Region EBA, Cordillera de la Costa Central EBA and Cordillera de Mérida EBA. Locally common. Readily accepts man-made habitats such as plantations, parks, gardens, etc. with scattered stands of shrubs and trees.

Bibliography. Behnke-Pedersen (1972), Meyer de Schauensee (1982), Meyer de Schauensee & Phelps (1978), Olrog (1968), Phelps & Phelps (1958), Renjifo *et al.* (1997), Rodner (1995), Schäfer & Phelps (1954), Stattersfield *et al.* (1998), Stoltz *et al.* (1996), Todd (1942), Wetmore (1939).

100. Short-tailed Emerald

Chlorostilbon poortmani

French: Émeraude à queue courte

Spanish: Esmeralda Colicorta

German: Kurzschwanz-Smaragdkolibri

Other common names: Berlepsch's Emerald ("inexpectatus")

Taxonomy. *Ornismya poortmani* Bourcier, 1843, Colombia.

Possibly forms a superspecies with *C. stenurus* and *C. alice*. Race *euchloris* has sometimes been considered a separate species, due mainly to suggestion of possible overlap in range, but poorly known. Forms "*inexpectatus*" and "*auratus*", known by single specimens from "Bogotá" and "Peru" respectively, are apparently aberrant individuals of present species. "*Ptichoptera iolaima*", known from a specimen taken at Ypanema, São Paulo (Brazil), is probably a hybrid between present species and *C. alice*. Two subspecies recognized.

Subspecies and Distribution.

C. p. euchloris (Reichenbach, 1854) - C Colombia (W slope of E Andes S to Huila, and E slope in Santander).

C. p. poortmani (Bourcier, 1843) - E Colombia (E slope of E Andes, from Boyacá S to W Meta) and NW Venezuela (Mérida and Táchira).

Descriptive notes. Male 7.5-8.5 cm, female 6.5-7.5 cm; 3-4 g. Male has short, straight, black bill; forehead iridescent green, crown bronzy-green, all upperparts, wing-coverts and tail-coverts are bronzy-green; underparts, including undertail-coverts, are brilliant glittery green; tail forked, short, iridescent bronzy-green. Female has bill like male; forehead dull green, crown dull bronzy-green; upperparts similarly coloured to those of male, but far less brilliant; underparts grey; tail forked, short, central tail feathers green, others basally dull turquoise shading to dark blue, tipped pale grey. Immature resembles adult female but with

buffy fringes on head feathers. Race *euchloris* very similar but slightly larger, with slightly more golden tinge to crown and underparts.

Habitat. Humid forest, forest edge, open woodland, second growth, plantations, usually along stream, at 100-2400 m.

Food and Feeding. Visits non-pendent flowers such as *Elleanthus*, *Guzmania* and *Phaseolus*. Mostly a trap-liner at scattered low flowers 0.6-4 m above ground in rather open areas. In coffee plantations feeds on nectar of flowering *Inga* trees. Insects are caught in the air by hawking.

Breeding. May-Jun. Cup-shaped nest has a thin and soft texture created by cotton or fibrous fluff; outside decorated with fragments of leaves, branches, fine roots, moss and scales of Cycadaceae. Clutch size 2; incubation 15-16 days, by female; chick darkish grey with two dorsal rows of dark down; fledging period 20-22 days. First breeding in second year.

Movements. Sedentary.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species; present in Cordillera de Mérida EBA and Colombian East Andes EBA. Generally common throughout much of its extensive range. Readily accepts man-made habitats.

Bibliography. Fjeldså & Krabbe (1990), Hilty & Brown (1986), Meyer de Schauensee (1982), Meyer de Schauensee & Phelps (1978), Olivares (1969), Olrog (1968), Phelps & Phelps (1958), Ruschi (1949b), Salaman & Mazariegos (1998a), Snow & Snow (1980), Stattersfield *et al.* (1998), Stoltz *et al.* (1996), Todd (1942).

Genus *PANTERPE* Cabanis & Heine, 1860

101. Fiery-throated Hummingbird

Panterpe insignis

French: Colibri insigne **German:** Feuerkehlkolibri **Spanish:** Colibrí Insigne
Other common names: Irazu Hummingbird

Taxonomy. *Panterpe insignis* Cabanis and Heine, 1860, "San José" (probably Volcán Irazú), Costa Rica.

Relationships uncertain. Two subspecies recognized.

Subspecies and Distribution.

P. i. eisenmanni Stiles, 1985 - N Costa Rica (Cordillera de Guanacaste).

P. i. insignis Cabanis & Heine, 1860 - NC Costa Rica (Cordillera de Tilarán) S to extreme W Panama.

Descriptive notes. 10.5-11 cm; male 5.9-6.2 g, female 4.9-5.2 g. Sexes alike. Bill black except basal part of lower mandible pink, feet dusky grey. Crown glittering royal blue, sides of head and nape black, small white postocular spot; back bright metallic green, shading to bluish-green on uppertail-coverts; tail blue-black; throat golden green laterally, shading to brilliant rosy copper-orange centrally; violet-blue patch on centre of breast; belly and vent bright green to blue-green. Immature has rusty borders to feathers of face and nape. Race *eisenmanni* slightly smaller than nominate with blue-violet of chest extending to belly, black

of nape extending to upper back, uppertail-coverts mostly blue, bill much shorter.

Habitat. Montane forest, cloudforest including elfin forest, timberline shrubbery of sub-*páramo*, clearings and second growth adjacent to forest, highland pastures with many remnant trees. Mostly in canopy inside forest, descending to shrub level at edges and in adjacent clearings. At 2200-3200m in higher mountains; in lower cordilleras of N and NC Costa Rica occurs from 1600-1800 m to summits.

Food and Feeding. Visits a wide variety of flowers of epiphytes (bromeliads, ericads, gesneriads), shrubs and small trees (*Gaiadendron*, *Vaccinium*, *Cestrum*, *Centropogon*, *Fuchsia*), vines (*Tropaeolum*, *Bomarea*), herbs (*Salvia*) and those of *Clusia* trees in cloud and elfin forest. Pierces longer flowers of *Centropogon* and *Fuchsia*, or uses holes made by bumblebees or flowerpiercers (*Diglossa*) to reach nectar. Very aggressive and dominant at flowers, both sexes frequently defending feeding territories outside the breeding season. Frequently hawks small flying insects, less often gleans arthropods from foliage.

Breeding. Aug-Jan in Costa Rica. During breeding males do not lek but defend rich patches of flowers, usually of ericads (*Macleania*, *Cavendishia*) into which they allow females with whom they mate. Nest a bulky cup of treefern scales, plant down and cobweb, heavily decorated on the outside with green moss and bits of lichen, attached to tip of drooping bamboo stem inside forest or dangling root under overhanging bank of road-cut, 2-4 m above ground. Clutch size 2. No further information.

Movements. Following breeding at least part of population moves to lower elevations, down locally to 1400-1600 m, rarely to 700 m.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species: present in Costa Rica and Panama Highlands EBA. Species is generally common to abundant over most of range. Large areas of its montane habitats are protected in national parks or forest reserves in Costa Rica and Panama, e.g. Volcán Irazú and Volcán Poás National Parks and Monteverde Biological Reserve (Costa Rica).

Bibliography. Anon. (1998a), Blake (1958), Feinsinger (1980), Fogden (1993), Law & Fogden (1981), Ridgely & Gwynne (1989), Skutch (1967), Slud (1964), Stattersfield *et al.* (1998), Stiles (1983b, 1985a, 1985c), Stiles & Skutch (1989), Stotz *et al.* (1996), Tramer & Simmers (1994), Wetmore (1968a), Wolf (1969, 1976), Wolf & Hainsworth (1972), Wolf & Stiles (1970), Wolf *et al.* (1976).

Genus *ELVIRA* Mulsant *et al.*, 1866

102. White-tailed Emerald

Elvira chionura

French: Colibri elvire **German:** Grüner Elvirakolibri **Spanish:** Esmeralda Elvira

Taxonomy. *Trochilus* (*Thaumantias*?) *chionura* Gould, 1851, David, Chiriquí, Panama.

Genus sometimes merged into *Eupherusa*. Monotypic.

Distribution. Pacific slope from S Costa Rica to C Panama; reaches Caribbean slope locally in Panama.

Descriptive notes. 7.5-8 cm; male 3.3 g, female 3.1 g. Bill nearly straight, black except for pinkish basal half of lower mandible, feet dark grey. Male bronzy-green above, shading to dark copper-bronze on uppertail-coverts and central rectrices; outer 3 rectrices white, tipped black; below mostly glittering green, belly, vent and undertail-coverts white. Female dull white below flecked with green laterally and bronzy-green on flanks; central rectrices bronzy, outer 3 white crossed by diagonal black subterminal band. Immature male duller green below than adult, with greyish-buff feather fringes; immature female greyer below than adult, green lateral spotting duller, more bronzy and

Movements. Not well understood; outside breeding season recorded both above and below breeding areas in Costa Rica.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species: present in Costa Rica and Panama Highlands EBA. Locally common in lower part of La Amistad National Park and at Las Cruces Biological Station in Costa Rica; however, deforestation extensive and continuing in at least the lower part of its altitudinal range in both Costa Rica and Panama; its current status requires more thorough documentation.

Bibliography. Anon. (1998a), Blake (1958), Hernández-Baños *et al.* (1995), Renjifo *et al.* (1997), Ridgely & Gwynne (1989), Slud (1964), Stattersfield *et al.* (1998), Stiles (1985c), Stiles & Skutch (1989), Stotz *et al.* (1996), Wetmore (1968a).

103. Coppery-headed Emerald

Elvira cupreiceps

French: Colibri à tête cuivrée **Spanish:** Esmeralda Capirotada
German: Bronzekopf-Elvirakolibri

Taxonomy. *Eupherusa cupreiceps* Lawrence, 1866, Barranca, Costa Rica.

Genus sometimes merged into *Eupherusa*. Species has occasionally been awarded monospecific genus *Lawrencius*. Population of Cordillera de Guanacaste (N Costa Rica) probably deserves recognition as a separate race. Monotypic.

Distribution. Highlands of N & C Costa Rica: Caribbean slope, reaching Pacific slope in upper parts of N Cordillera de Guanacaste and N Cordillera de Tilarán.

Descriptive notes. 7.5 cm; male 3.4 g, female 3.1 g. Distinctly decurved bill black except for pinkish base of lower mandible. Male has crown, uppertail-coverts and central rectrices copper-bronze, otherwise bronzy-green above, glittering green below, vent and undertail-coverts white, 3 lateral rectrices white, tipped dark grey. Female has crown and back green, underparts dull white speckled laterally with brown, white outer rectrices crossed by a broken blackish band. Male in Cordillera de Guanacaste differs from those in remainder of range in possessing a distinct purple spot in centre of lower breast. Young male has under-

parts dull bronzy-green, crown dull green only slightly tinged with copper; both sexes show cinnamon fringes to feathers on face, nape and rump.

Habitat. Cool, wet highland forests, forest edge, pastures with many remnant forest trees, shaded coffee plantations, old second growth. In forest, male mostly in canopy, female more in understorey; both sexes at all levels along edges and in semi-open, second growth. Breeds mainly at 700-1500 m, lower outside breeding season.

Food and Feeding. Takes nectar from flowers of various trees (*Quararibea*, *Pithecellobium*, *Guarea*, *Clusia*), epiphytes (especially Ericaceae, Gesneriaceae), shrubs (Acanthaceae, *Besleria*) in forest, and of *Inga* trees and *Stachytarpheta* shrubs in and beside coffee plantations and in second growth. Takes arthropods by flycatching, usually sallying from perch, and by gleaning from foliage at all levels.

Breeding. In wet and early dry seasons, Oct-Mar. During breeding season males form leks of 3-6. Nest a neat cup of treefern scales, plant down and spiderweb, heavily decorated with moss and a few bits of lichen, 1-3 m above ground in shrub or fern in forest understorey, at edge, or along trail, stream, etc. Clutch size 2. No further information.

Movements. Makes pronounced altitudinal movements, bulk of population descending to 300-600 m, occasionally lower, following breeding.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species: present in Costa Rica and Panama Highlands EBA. Common over most of range, which includes large protected areas in all cordilleras, e.g. Braulio Carrillo, Rincón de la Vieja and Guanacaste National Parks, and Monteverde Biological Reserve.

Bibliography. Anon. (1998a), Feinsinger (1976, 1977, 1980), Fogden (1993), Hernández-Baños *et al.* (1995), Renjifo *et al.* (1997), Ridgway (1911), Slud (1964), Stattersfield *et al.* (1998), Stiles (1985b, 1985c), Stiles & Skutch (1989), Stotz *et al.* (1996).

Genus *EUPHERUSA* Gould, 1857

104. Oaxaca Hummingbird

Eupherusa cyanophrys

French: Colibri d'Oaxaca **German:** Blauscheitkolibri **Spanish:** Colibrí Oaxaqueño

On following pages: 105. White-tailed Hummingbird (*Eupherusa poliocerca*); 106. Stripe-tailed Hummingbird (*Eupherusa eximia*); 107. Black-bellied Hummingbird (*Eupherusa nigriventris*); 108. Pirre Hummingbird (*Goethalsia bella*); 109. Violet-capped Hummingbird (*Goldmania violiceps*); 110. Dusky Hummingbird (*Cyananthus sordidus*); 111. Broad-billed Hummingbird (*Cyananthus latirostris*); 112. Blue-headed Hummingbird (*Cyanophaea bicolor*).

Other common names: Blue-capped Hummingbird

Taxonomy. *Eupherusa cyanophrys* Rowley and Orr, 1964, 11 miles [c. 18 km] south of Juchatengo, south-western Oaxaca, Mexico.

Forms a superspecies with *E. polioerca* and *E. eximia*; sometimes regarded as a race of former, but morphological differences justify status as separate full species. Monotypic.

Distribution. Mountains of S Oaxaca (SC Mexico).

(mainly *Chusquea*), semi-deciduous forest, gallery forest, and cloudforest, at 700-2600 m, commonest below 1800 m. Forages in all strata.

Food and Feeding. Feeds on nectar of flowering *Inga*, *Kohleria*, *Lobelia*, *Malviscus*, *Manettia*, *Psittacanthus* and *Hamelia patens*; subordinate to other hummingbirds, such as *Amazilia*.

Breeding. Sept-Nov. May. Cup-shaped nest, made of moss, lined with plant down, exterior decorated with lichens, two nests incorporated flowers of *Salvia*; placed in forks of small bushes, exposed roots, and small trees, 1-2-6 m above ground. The 6 m record is probably an exception since it was located in a steep road cutting on an exposed pine root. Clutch size 2, incubation by female. No further information.

Movements. Sedentary; some seasonal vertical dispersal to lower and higher elevations.

Status and Conservation. **ENDANGERED.** CITES II. Restricted-range species: present in Sierra Madre del Sur EBA. Locally common but highly restricted in range. Habitat is unprotected and threatened by deforestation. Shortly after its discovery it was realized that species was vulnerable to deforestation resulting from the methods used by local human population to cultivate corn; the preferred slash-and-burn practices cause severe damage to remaining forest areas. Species frequently recorded in the area around Santa Rosa and Río Salado, and between Pluma Hidalgo and La Soledad.

Bibliography. Anon. (1998a), Binford (1989), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Hernández-Baños *et al.* (1995), Howell & Webb (1995a), Johnsgard (1997), Mayr (1971), Roberson & Carratello (1997), Rowley (1966), Rowley & Orr (1964), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Webster (1965), Wege & Long (1995).

105. White-tailed Hummingbird

Eupherusa polioerca

French: Colibri du Guerrero **German:** Weißschwanzkolibri **Spanish:** Colibrí de Guerrero

Taxonomy. *Eupherusa polioerca* Elliot, 1871, Putla, Oaxaca, Mexico.

Forms a superspecies with *E. cyanophrys* and *E. eximia*; sometimes regarded as conspecific with former, but morphological differences justify their separation as two full species. Monotypic.

Distribution. Pacific slope of Guerrero (Sierra Madre del Sur) and W Oaxaca, S Mexico.

Food and Feeding. Feeds on nectar of flowering *Inga*, *Kohleria*, *Lobelia*, *Malviscus*, *Manettia*, *Psittacanthus* and *Hamelia patens*; subordinate to other hummingbirds like *Amazilia*.

Breeding. One nest has been found in Oct, birds in breeding condition in Feb and Apr. No further data available.

Movements. Sedentary; some altitudinal dispersal likely.

Status and Conservation. **ENDANGERED.** CITES II. Restricted-range species: present in Sierra Madre del Sur EBA. Still locally common within its restricted range. Although may accept man-made habitats like coffee plantations to some extent, species is threatened by destruction of its natural habitat by deforestation. Common in the Omiltemi State Ecological Park, which is protected; however, most of range remains unprotected.

Bibliography. Anon. (1998a), Binford (1989), Ceballos-Lascurain (1989), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Friedmann *et al.* (1950), Hartert & Hartert (1894), Hernández-Baños *et al.* (1995), Howell & Webb (1995a), Johnsgard (1997), Knox & Walters (1994), Mayr (1971), Montes de Oca (1875), Navarro (1992), Navarro & Muñoz (1990), Navarro *et al.* (1991), Ornelas (1987), Rowley & Orr (1964), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Wege & Long (1995).

106. Stripe-tailed Hummingbird

Eupherusa eximia

French: Colibri à épaulettes **German:** Streifenschwanzkolibri **Spanish:** Colibrí Colirrayado

Taxonomy. *Ornismya eximia* DeLattre, 1843, Cobán, Guatemala.

Forms a superspecies with *E. cyanophrys* and *E. polioerca*. Three subspecies recognized.

Subspecies and Distribution.

E. e. nelsoni Ridgway, 1910 - E & SE Mexico.

E. e. eximia (DeLattre, 1843) - extreme E Mexico S through highlands to C Nicaragua.

E. e. egregia P. L. Sclater & Salvin, 1868 - highlands of Costa Rica and W Panama.

upperparts. Male of *nelsoni* more yellowish-green below, black tips of outer rectrices more diffuse; *egregia* has black of outer webs of lateral rectrices restricted to narrow border; in latter race these feathers usually wholly white in female.

Habitat. Canopy and borders of cool, wet highland forest, descending to shrub level in gaps, along forest borders, or in adjacent semi-open or second growth vegetation; only nesting female regularly uses heavily shaded forest understory, especially in ravines and near streams. Occurs at 1000-1800 m (Honduras), mostly 800-2000 m (Costa Rica), 1200-2500 m (Panama).

Food and Feeding. Visits flowers of a variety of trees, including *Inga* and *Clusia*, shrubs, especially Acanthaceae and Rubiaceae, also *Besleria* and *Salvia*, and epiphytes, notably Ericaceae and Gesneriaceae. Sometimes pierces long corollas; male in particular often very aggressive and territorial at flowers. Flycatches especially at gaps and edges, and gleans arthropods from foliage and mossy trunks.

Breeding. Late wet into dry season, Sept-Mar or Apr in Costa Rica; Apr-Jun in Oaxaca, Mexico. Nest a neat cup of pale-colored plant down, fine fibres, treefern scales and cobweb, decorated on outside with moss and lichens, usually including bits of a bright red lichen, 1-3 m up in dark forest understory, often near a stream. No further information.

Movements. In Costa Rica and probably Panama often descends to lower elevations, locally down to 250-300 m, during non-breeding season; immediately following breeding, small numbers may also range upslope, to 2500 m or more.

Status and Conservation. Not globally threatened. CITES II. Locally uncommon to common over most of range, where deforestation has not been severe. Regularly recorded in the Mayan ruins of Palenque, Chiapas (Mexico), and at Monteverde Biological Reserve (Costa Rica). In Mexico, populations of race *nelsoni* may be under pressure from habitat destruction, but more information required on current situation.

Bibliography. Anon. (1998a), Binford (1989), Blake (1958), Carroll & Moore (1993), Feinsinger (1976, 1977, 1980), Feinsinger *et al.* (1987), Fogden (1993), Friedmann *et al.* (1950), Howell & Webb (1995a), Howell *et al.* (1992), Johnsgard (1997), Land (1970), Monroe (1968), Paynter (1957), Renjifo *et al.* (1997), Ridgely & Gwynne (1989), Ridgway (1911), Rowley (1984), Russell (1964), Slud (1964), Stiles (1985c), Stiles & Skutch (1989), Stotz *et al.* (1996), Thomas *et al.* (1986), Wetmore (1968a).

107. Black-bellied Hummingbird

Eupherusa nigriventris

French: Colibri à ventre noir **German:** Schwarzbauchkolibri **Spanish:** Colibrí Ventrinegro

Taxonomy. *Eupherusa nigriventris* Lawrence, 1867, Costa Rica.

In past, sometimes segregated in monospecific genus *Callipharus*. Monotypic.

Distribution. Highlands of Caribbean slope from C Costa Rica to W Panama.

Descriptive notes. 7.5-8.5 cm; male 3-7 g, female 3-3 g. Rather short blackish bill, slightly decurved. Bronzy-green above, dusker on central rectrices; male has forecrown, face and underparts velvety black; female grey below flecked laterally with bronze-green; rufous patch on secondaries, smaller and duller in female. Outer 3 rectrices mostly white. Immature male has black of face and underparts replaced by dark sooty bronze; young of both sexes with dusky fringes on feathers of face, crown, nape and rump; dark border of outer web of third rectrix wider and more diffuse.

Habitat. Cool, wet highland forest, forest edge, adjacent semi-open vegetation including shaded pastures and coffee plantations, tall second growth. Mostly at 900-2000 m in Costa Rica, 1300-1800 m in Panama. In forest, male mostly in upper understory and canopy, female in understory; both sexes descend to shrub level along edges and gaps and in second growth.

Food and Feeding. In forest, male visits mostly flowers of trees (*Inga*, *Calliandra*, *Pithecellobium*, *Clusia*) and epiphytes (Ericaceae, *Columnnea*, *Norantea*, *Elleanthus*), female more at flowers of shrubs like *Besleria*, *Cephaelis*, or *Witheringia*; both sexes at *Stachytarpheta* along borders of coffee plantations. Male aggressive, and sometimes territorial at flowers not claimed by larger, dominant species like *Lampornis hemileucus*. Frequently sallies for flies and gnats from perches in canopy or along edges and in gaps; gleans arthropods from foliage along edges and streams.

Breeding. Wet to early dry seasons, Aug or Oct-Mar in Costa Rica. During breeding season male perches in tall shrubs or subcanopy along edges of forest gaps, solitary or more often in leks up to 5. Nest is a small cup chiefly of treefern scales and spiderweb, decorated sparingly with bits of moss and lichen, 2-4 m up in shrub in understory or at forest edge, usually where protected from above by large overhanging leaves. Clutch size 2; incubation 16 days.

Movements. Most of population in Costa Rica moves to lower elevations following breeding, locally down to 400-600 m.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species: present in Costa Rica and Panama Highlands EBA. Fairly common over most of range, which includes several large protected areas, e.g. Tapanti National Park (Costa Rica).

Bibliography. Anon. (1998a), Blake (1958), Hernández-Baños *et al.* (1995), Renjifo *et al.* (1997), Ridgely & Gwynne (1989), Skutch (1967), Slud (1964), Stattersfield *et al.* (1998), Stiles (1985b, 1985c), Stiles & Skutch (1989), Stotz *et al.* (1996), Wetmore (1968a).

Genus *GOETHALSIA* Nelson, 1912

108. Pirre Hummingbird

Goethalsia bella

French: Colibri du Pirré **German:** Rotgesichtkolibri **Spanish:** Colibri del Pirre
Other common names: Rufous-cheeked/Goethals's Hummingbird

Taxonomy. *Goethalsia bella* Nelson, 1912. Cana, 2000 feet [c. 600 m], Panama. Considered a close relative of *Goldmania* and perhaps of *Hylocharis*, sharing with former the long, stiffened central undertail-coverts; behaviour and external morphology show similarities with *Eupherusa*. Monotypic.
Distribution. E Panama (Cerro Sapo and Cerro Pirre, in Darién) and extreme NW Colombia (Alturas de Nique, Chocó).

Descriptive notes. 8.4-9.5 cm; male 4 g, female 3 g. Male has straight black bill, with reddish mandible; forehead and lores rufous chestnut, upperparts metallic green; chin rufous chestnut, rest of underparts shining green; secondaries with buff patch; tail rufous tipped black, central pair of feathers green. Female similar to male but throat rufous buff, rest of underparts whitish. Immature similar to adult female.

Habitat. Forest and forest borders of foothills and mountain ranges between 600 and 1500 m; at Cerro Pirre, mostly found above 1000 m. Forages from near ground to mid-strata in the forest interior.

Food and Feeding. Feeds on flowering shrubs or small trees such as Ericaceae and Rubiaceae.

Breeding. No data available.

Movements. Sedentary.

Status and Conservation. Not globally threatened. CITES II. Currently considered Near-threatened. Restricted-range species: present in Darién Highlands EBA. Generally uncommon throughout its small range, and usually seen individually; abundance increases with altitude. Habitat on Cerro Pirre not threatened at present. A little-known species.

Bibliography. Anon. (1998a), Hilty & Brown (1986), Meyer de Schauensee (1982), Olog (1968), Ridgely & Gwynne (1989), Robbins *et al.* (1985), Somarriba (1984), Stattersfield *et al.* (1998), Sotz *et al.* (1996), Wetmore (1968a).

Genus *GOLDMANIA* Nelson, 1911

109. Violet-capped Hummingbird

Goldmania violiceps

French: Colibri à calotte violette **German:** Violettkeppenkolibri **Spanish:** Colibri de Goldman
Other common names: Goldman's Hummingbird

Taxonomy. *Goldmania violiceps* Nelson, 1911. Cerro Azul, 3000 feet [c. 1000 m], north-west of Chepo, Panama. Linked with *Goethalsia*, with which shares the long, stiffened central undertail-coverts; one proposal, based on external morphology, suggests placing present species in *Hylocharis*; general behaviour, however, indicates close affinities with *Chlorostilbon*. Monotypic.

Distribution. C Panama (Cerro Azul, Cerro Bruja, Cerro Tacarcuna) to extreme NW Colombia.

Descriptive notes. 8.5-9.5 cm; male 4-4 g, female 3-5. Male has straight black bill, lower mandible basally flesh-coloured; crown iridescent violet-blue; back and underparts metallic green; undertail-coverts green, with central feathers white and stiffened; tail slightly forked, maroon, broadly bordered with bronze; white femoral tufts. Female green above, whitish below, with grey spots on throat and green discs on sides; tail similar to male's, but tipped white. Immature resembles adult female.

Habitat. Humid forest and forest edges between 600 and 1200 m, commonest around 900 m. Forages mainly low down in dense undergrowth.

Food and Feeding. Nectar of low flowering shrubs, including *Salvia*, *Pachystachis*, *Palicourea* and *Psammisia*.

Breeding. Nests have been found Dec to Mar; no further information available.

Movements. Sedentary.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species: present in Darién Highlands EBA. Fairly common to locally common (Cerro Azul and Cerro Jefe). Many parts of the montane habitats of this species as yet largely unaltered by man.

Bibliography. Anon. (1998a), Hilty & Brown (1986), Meyer de Schauensee (1982), Olog (1968), Ridgely & Gwynne (1989), Stattersfield *et al.* (1998), Sotz *et al.* (1996), Wetmore (1968a).

Genus *CYNANTHUS* Swainson, 1827

110. Dusky Hummingbird

Cyananthus sordidus

French: Colibri sombre **German:** Grauer Breitschnabelkolibri **Spanish:** Colibri Prieto

Taxonomy. *Cyanomyia* (?) *sordida* Gould, 1859. Oaxaca, Mexico.

Possibly forms a superspecies with *C. latirostris*; a reported hybrid of these two apparently refers to variation within adult male of present species. Monotypic.

Distribution. S Mexico, from Michoacan to Oaxaca.

Descriptive notes. 9-10 cm; 4.3-4.7 g. Male has slightly decurved bill, red, tipped black; crown dull green, auriculars blackish, rest of upperparts dull golden green, postocular stripe white, underparts dusky grey; tail slightly forked, greyish-green. Female similar to male, bill with upper mandible black, lower red tipped black; underparts paler; outer rectrices with blackish subterminal bar, tipped white. Immature resembles adult female but tips of outer rectrices pale buff.

Habitat. Open and semi-open arid areas with scattered trees and scrub, sometimes along roadsides or in flowering gardens, at 900-

2200 m. Forages in mid to upper strata.

Food and Feeding. No specific food plants have been recorded; presumably feeds on nectar of flowering *Agave*, *Castilleja* and *Opuntia*. Insects are caught in the air by hawking.

Breeding. Nests have been recorded Mar-May, Aug, Nov-Dec. When nesting, may be capable of adapting to more humid periods within its semi-arid habitat. Nest small, cup-shaped, placed in forks or attached to hanging twigs, built of soft plant material, exterior decorated with pieces of dead leaves, small twigs and cotton, but very seldom lichens. Clutch size 2. No further information.

Movements. Sedentary.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species: present in Balsas Region and Interior Oaxaca EBA. Common throughout most of range; no threats noted to date. Readily accepts man-made habitats such as flowering gardens. Occurs at Cañón de Lobos (Morelos), Laguna San Felipe (Puebla), Sierra de Atoyac (Guerrero) and Monte Albán and Teotitlán del Valle (Oaxaca).

Bibliography. Anon. (1998a), Binford (1985, 1985), Friedmann *et al.* (1950), Howell & Webb (1995a), Hutto (1985), Johnson (1997), Mayr & Short (1970), Ridgway (1911), Rowley (1984), Stattersfield *et al.* (1998), Sotz *et al.* (1996), Wagner (1946a).

111. Broad-billed Hummingbird

Cyananthus latirostris

French: Colibri ciré **German:** Blaukehl-Breitschnabelkolibri **Spanish:** Colibri Piquiancho
Other common names: Doubleday's Hummingbird (*doubledayi*); Lawrence's Hummingbird (*lawrencei*)

Taxonomy. *Cyananthus latirostris* Swainson, 1827, tableland of Mexico; error = Valley of Mexico near Mexico City.

Possibly forms a superspecies with *C. sordidus*; a reported hybrid of these two apparently refers to variation within adult male of that species. Hybrids with *Agyrtia violiceps* and *Eugenes fulgens* documented suggest possible close relationship between these genera and *Cyananthus*. Race *doubledayi* sometimes considered a separate species; proposed race *tonoi* represents specimens from zone of intergradation between *propinquus* and *doubledayi*; proposed race *nitidus* is synonym of *doubledayi*. Race *lawrencei* has also been considered a distinct species. Racial differences mainly in male head coloration, though this may vary clinally, so number of valid races uncertain. Five subspecies recognized.

Subspecies and Distribution.

C. l. magicus (Mulsant & J. Verreaux, 1872) - S Arizona and SW New Mexico (SW USA) S to Nayari (CW Mexico).

C. l. latirostris Swainson, 1827 - San Luis Potosí and Tamaulipas to N Veracruz (EC Mexico).

C. l. lawrencei (Berlepsch, 1887) - Is Tres Marias (off W coast of Mexico).

C. l. propinquus R. T. Moore, 1939 - Guanajuato to Michoacan (C Mexico).

C. l. doubledayi (Bourcier, 1847) - Guerrero, Oaxaca and Chiapas (S Mexico).

Descriptive notes. 9-10 cm; 3.2-4.4 g. Male has straight bill, bright red with black tip; crown, nape and back emerald green; throat blue to violet-blue, rest of underparts metallic bronzy-green, undertail-coverts dusky white; tail slightly forked, blue-black with central rectrices tipped greyish. Female has white postocular stripe and dull green crown, back golden-green to emerald green; throat and underparts greyish; tail green to blue-green with subterminal blue-black band, tipped white. Immature resembles adult female; immature male has tail blue-black and underparts with blue and green patches. Race *magicus* has greenish

throat; *lawrencei* similar to nominate but throat turquoise-green in male, and tail is more deeply cleft; *propinquus* differs in darker coloration, crown metallic green, underparts bluish; *doubledayi* similar to nominate but forecrown of male iridescent blue-turquoise, throat deeper violet-blue, underparts generally bluer, undertail-coverts black.

Habitat. In USA, rocky canyons in deserts where natural streams or springs support vegetation; common vegetation used includes sycamore (*Platanus*) and mesquite (*Prosopis*). In Mexico, where found from sea-level to above 2000 m, habitat highly variable but typically arid to semi-arid bushy woodland, scrub and fairly open areas with some trees.

Food and Feeding. Forages on floral nectars of flowering *Agave*, *Caesalpinia*, *Castilleja* and *Opuntia*. Arthropod diet includes spiders, flies (Diptera), Hymenoptera and others.

Breeding. Breeding occurs in USA during peak flowering seasons between Apr and Sept; in Mexico breeding variable, possibly extending from Dec to Aug. In Arizona, nest density in a given area dependent upon nectar availability. Nest is cup-shaped, lined with soft downy plant material, exterior covered with leaves and bark (rarely lichens) glued in place with spiders' webs, 1.5-4 m above ground. Clutch size 2.

Movements. Migratory in USA and extreme N Mexico; resident elsewhere in its breeding range. N migrants winter S to N Guerrero; questionable reports of wintering in Oaxaca. Birds in USA begin arriving at some locations mid-Mar and depart by mid-Oct. Several extralimital records during breeding season likely to be result of post-breeding wandering; vagrant to Baja California, Oct-Jan.

Status and Conservation. Not globally threatened. CITES II. Common in USA; locally common to fairly common in Mexico. Despite use of a variety of habitats, their possible destruction may be a potential threat for the future throughout the species' range.

Bibliography. Arizmendi & Ornelas (1990), Baicich & Harrison (1997), Baltosser (1986a, 1989b), Bent (1940), Binford (1985, 1989), Blake & Hanson (1942), Brandt (1951), Contreras-Balderas (1997), Cottam & Knappen (1939), DeGraaf & Rappole (1995), Des Granges & Grant (1980), Friedmann *et al.* (1950), Gray (1958), Griscom (1934), Hejl *et al.* (1995), Howeli & Webb (1992b, 1995a), Johnsgard (1997), Kaufman (1996), Mayr & Short (1970), McCaskie (1970), Montgomerie (1979), Moore (1939a), Oberholser (1974), Parra *et al.* (1993), Phillips (1964), Phillips *et al.* (1964), Price *et al.* (1995), Ridgway (1911), van Rossem (1945a), Rowley (1984), Schaldach (1963), Short & Phillips (1966), Small (1994), Stotz *et al.* (1996), Wagner (1952, 1957b), Woodier (1998).

Genus *CYANOPHAI* Reichenbach, 1854

112. Blue-headed Hummingbird

Cyanophaia bicolor

French: Colibri à tête bleue

German: Blaukopfkolibri

Spanish: Colibrí Bicolor

Other common names: Wagler's Woodnymph

Taxonomy. *Trochilus bicolor* J. F. Gmelin, 1788, Guadeloupe; error = Dominica.

Relationships of genus unclear; nest type indicates affinities with *Chlorostilbon* and *Cyananthus*, voice with *Thalurania*. Monotypic.

Distribution. Dominica and Martinique.

Descriptive notes. 9-11 cm; male 4-7 g, female 4-5 g. Male has straight black bill, pinkish red on basal portion of lower mandible; head metallic violet-blue, back shining green, uppertail-coverts

deep blue; chin and throat violet-blue, rest of underparts metallic green, with faint blue gloss; tail forked, steel blue. Female has bill similar to male's, but entirely black; head shining green above, loreal and auricular region dusky, postocular spot dull grey; back bronze-green; underparts pale brownish-grey, bronze-green on sides; tail shining bronze at base, outer rectrices with broad steel blue sub-terminal band and large grey tips. Immature like adult female but head feathers pale green with brown fringes.

Habitat. Virgin forest, forest edges and along secondary growth of rivers in the mountains.

Rare at sea-level. Most numerous between 800 and 1000 m.

Food and Feeding. Nectar of flowering plants from ground to tree tops, such as *Pachystachys*, *Asclepias*, *Begonia*, *Costus*, *Besleria*, *Duranta* and *Inga*. Sallies for insects over mountain streams or collects arthropods from leaves.

Breeding. Mar-May. Cup-shaped nest of fine plant fibres like fluff from silk-cotton tree or brown soft parts from outer cover of tree ferns, placed at height of 1-4 m on horizontal twigs or fern fronds. Usually decorated with attached strips of dead leaves from *Heliconias* and ferns. Clutch size 2; incubation 16-18 days, by female; chick flesh-coloured with pale grey dorsal down; fledging period 20-23 days; young remain with female for 3-4 weeks. First breeding in second year.

Movements. Sedentary.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species; present in Lesser Antilles EBA. Patchy distribution on both islands. Densities in rainforest between Fort-de-France and Morne Rouge, Martinique, at least 3-4 individuals/km². Formerly more numerous on Dominica but hurricanes in the early 1980's almost extirpated the local population, which is now slowly recovering.

Bibliography. Anon. (1998a), Bon Saint Côme (1982), Bond (1985), Ingels (1976a), Raffaele *et al.* (1998), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Tyrrell & Tyrrell (1990).

PLATE 55

inches 2
cm 5

Genus *THALURANIA* Gould, 1848

113. Mexican Woodnymph

Thalurania ridgwayi

French: Dryade du Mexique German: Mexikonympe Spanish: Zafiro Mexicano

Taxonomy. *Thalurania ridgwayi* Nelson, 1900, San Sebastian, Jalisco, Mexico. Forms a superspecies with *T. colombica*, *T. fannyi* and *T. furcata*; species limits unclear, and all four have been considered conspecific. Alternatively, blue-crowned present species often considered a race of purple-crowned *T. colombica*. Monotypic.

Distribution. Pacific slope of Mexico, in S Nayarit, Jalisco and Colima.

Descriptive notes. 9-10 cm; male 3.5-4.2 g, female c. 3.5 g. Male has straight black bill; forehead iridescent violet-blue, hindcrown bluish-green, rest of upperparts green; throat iridescent emerald green, belly and undertail-coverts dusky green; tail slightly forked, bluish-black. Female upperparts similar to male, small white postocular spot; below greyish, side of breast with some green discs; tail slightly forked, bluish-black, central pair of rectrices with greenish shine, outer rectrices tipped white. Immature unknown.

Habitat. Humid forest, canyons and foothills at 250-1200 m; exact habitat requirements are

still unknown; probably also occurs in coffee plantations.

Food and Feeding. No specific food plants have been recorded, but presumably feeds on nectar of flowering Rubiaceae, Zingiberaceae and epiphytes (bromeliads, Ericaceae and mistletoes) like other *Thalurania*. Arthropods are gleaned from foliage and caught in the air by hawking.

Breeding. Birds in breeding condition collected Feb-Mar. No further information.

Movements. Sedentary.

Status and Conservation. VULNERABLE. CITES II. Restricted-range species: present in North-west Mexican Slope EBA. Rare to locally common. Frequently recorded at Puerto Los Mazos, on lower slope of Sierra de Manantlán Biosphere Reserve (Jalisco/Colima); also occurs in other protected areas e.g. Cerro San Juan Biosphere Reserve (Nayarit) and Nevados de Colima National Park (Jalisco/Colima). Although exact habitat requirements have not been documented, species is probably bound to forest habitats, which are under severe threat of destruction, though some suitable areas remain intact. Without more precise knowledge of ecological requirements, conservation planning is barely feasible; further investigation into life history urgently required.

Bibliography. Anon. (1998a), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Escalante & Peterson (1992), Friedmann *et al.* (1950), Hernández-Baños *et al.* (1995), Howell & Webb (1995a), Johnson (1997), Phillips (1961), Ridgway (1911), Schladach (1963), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Wege & Long (1995).

114. Purple-crowned Woodnymph

Thalurania colombica

French: Dryade couronnée German: Violetttronennympe Spanish: Zafiro Coroniazul
Other common names: Violet-crowned/Crowned Woodnymph: Colombian Woodnymph (*colombica*); Blue-crowned Woodnymph (*townsendi*)

Taxonomy. *Ornismya colombica* Bourcier, 1843, San Agustín, Magdalena Valley, Colombia. Forms a superspecies with *T. ridgwayi*, *T. fannyi* and *T. furcata*; species limits unclear, and all four have been considered conspecific. Alternatively, purple-crowned present species often treated as conspecific with blue-crowned *T. ridgwayi*, and sometimes also with green-crowned *T. fannyi*, forming a group with glittering crowns and more violet on back, as opposed to mostly dull-crowned, green-backed forms of *T. furcata*. Lump of present species with *T. fannyi* supported by their close similarity, and also by blue feathering at rear of crown in *T. fannyi*, a feature decreasing with distance from adjacent purple-crowned forms of present species; females too are very similar. Race *hypochlora* of *T. fannyi* may belong in present species. Race *rostrifera* may be inseparable from nominate. Race *townsendi* (with *venusta*) might be approaching separate species status. Four subspecies recognized.

Subspecies and Distribution.

T. c. townsendi Ridgway, 1888 - E Guatemala to SE Honduras.

T. c. venusta (Gould, 1851) - E Nicaragua to C Panama.

T. c. colombica (Bourcier, 1843) - N Colombia (S to head of Magdalena Valley) and NW Venezuela.

T. c. rostrifera Phelps & Phelps, Jr., 1956 - NW Venezuela (SW Táchira).

Descriptive notes. Male 9.5-10.5 cm, 4.3-4.6 g; female 8.5-9 cm, 3.9-4.1 g. Bill black, feet dark grey. Male has forehead and crown, belly and upper back violet, throat and chest glittering green, nape dark bronzy-green, lower back and rump dark bluish-green, tail blue-black and deeply forked. Female is bright green above, pale grey on the throat and chest and darker grey on the belly; the distal half of the tail is blue-black with the outer 3 rectrices white-tipped. Immature male of all races dull dusky green to bronze-green on crown and underparts, no glittering green or violet, tail shorter and less forked than those of adults; immature female

duller and bronzier green above with narrow buff fringes on face, nape and rump feathers. Race *rostrifera* differs mainly in longer bill; in *venusta*, male is larger and longer-tailed with the nape very dark blue-green, female has belly much darker, dusky grey glossed with green; in *townsendi* male has violet below restricted to sides, with green belly and bronzy nape, female dark grey below.

Habitat. Humid forest and adjacent edges, tall second growth and semi-open (cacao plantations, shaded gardens) vegetation, avoids open, scrubby areas. During breeding season male mainly in canopy, female more in understorey; at other times both sexes occur at all heights, lower along edges. Breeds from sea-level to 750-900 m (Costa Rica), 1600-1900 m (Colombia and Venezuela).

Food and Feeding. Visits flowers of a wide variety of epiphytes (bromeliads, Ericaceae, mistletoes, gesneriads, Marcgraviaceae), shrubs and small trees (*Besleria*, *Hamelia*, *Cephaelis*, *Cornutia*, *Acanthaceae*), less often those of larger trees like *Inga*; also fond of flowers of large herbs like *Heliconia* and *Costus*; prefers to visit flowers under partial to closed canopy rather than in open, male notably aggressive and frequently territorial at rich clumps of flowers. Frequently flycatches by sallying from perch in canopy or along edge or gap, also (especially female) gleans arthropods from foliage.

Breeding. Mainly during dry season (Feb-Jun) in Costa Rica; Mar-Jul or Aug, perhaps later, in N and C Colombia. Male may defend rich flowers to attract female. Nest a compact cup of treefern scales, plant down and cobweb, decorated on outside with lichens and moss, on horizontal twig of shrub under overhanging leaf, in forest; often at edge of small gap or trail, 1-5 m above ground.

Movements. In Costa Rica, part of population moves upslope to 1000-1200 m following breeding; also local movements following shifts in flowering. No information for other areas.

Status and Conservation. Not globally threatened. CITES II. One of the commonest forest hummingbirds over most of range, but suffering considerable habitat loss due to deforestation in many areas, notably parts of Central America and N Colombia. Occurs in several protected areas, e.g. Carara Biological Reserve, Gofito National Wildlife Refuge, and Corcovado and Braulio Carrillo National Parks (Costa Rica).

Bibliography. Ayala (1986), Chapman (1917, 1926), Escalante & Peterson (1992), Fogden (1993), Griscom (1932a), Hilty & Brown (1986), Howell, S.N.G. & Webb (1995a), Howell, T.R. (1957), Johnson (1997), Land (1970), Matheus *et al.* (1996), Meyer de Schauensee & Phelps (1978), Monroe (1968), Phelps & Phelps (1956), Ridgely & Gwynne (1989), Ridgway (1911), Skutch (1981), Slud (1960, 1964), Stiles (1975, 1980, 1985b, 1995a, 1995b), Stiles & Skutch (1989), Stone, J.L. (1996), Stone, W. (1932), Stotz *et al.* (1996), Todd & Carriker (1922), Weathers & Stiles (1989), Wetmore (1968a).

115. Green-crowned Woodnymph

Thalurania fannyi

French: Dryade de Fanny German: Grüntronennympe Spanish: Zafiro Coroniverde
Other common names: Emerald-bellied Woodnymph (*hypochlora*)

Taxonomy. *Trochilus Fannyi* DeLattre and Bourcier, 1846, Río Dagua, near Buenaventura, Colombia. Forms a superspecies with *T. ridgwayi*, *T. colombica* and *T. furcata*; species limits unclear, and all four have been considered conspecific. Alternatively, green-crowned present species sometimes considered conspecific with blue-crowned *T. ridgwayi* and purple-crowned *T. colombica*; this lump supported by great similarity of these forms, apart from crown colour of male, and indeed male of present species shows some blue feathering at rear of glittering green crown which decreases with distance from adjacent purple-crowned forms; also female plumages of present species and *T. colombica* very similar. Distinctive race *hypochlora* may be a separate species, or possibly referable to *T. colombica*. Race *subtropicalis* may not be distinguishable from *verticeps*. Four subspecies tentatively recognized.

Subspecies and Distribution.

T. f. fannyi (DeLattre & Bourcier, 1846) - E Panama and extreme NW to SW Colombia.

T. f. subtropicalis Griscom, 1932 - WC Colombia, in Cauca Valley and along adjacent W & C Andes.

T. f. verticeps (Gould, 1851) - Pacific slope of W Andes of extreme SW Colombia and NW Ecuador.

T. f. hypochlora Gould, 1871 - Pacific lowlands of Ecuador.

Descriptive notes. Male 9.5-10.5 cm, 4-7 g; female 8.5-9 cm, 4-2 g. Bill black, feet dusky grey in both sexes. Male has throat, chest and crown glittering green, the crown more bluish-green towards rear, sometimes with a few glittering blue-violet feathers along the hind margin; nape is dark bronze to bronze-green, most of the back and uppertail-coverts dark green to bronze-green; belly and a band across the upper back, violet; undertail-coverts more or less fringed with whitish, tail blue-black and deeply forked. Female green above, often more bronze-green on the crown and nape, with the shoulders usually distinctly blue; throat and upper breast very pale grey, belly dark dusky grey glossed with dark green; vent and undertail-coverts more or less whitish, tail blue-black with the outer 3 rectrices tipped with white. Immature male dull dusky bronze-green on crown and underparts with no glittering green or violet, tail shorter and less forked; immature female duller and bronzier green above with narrow buff fringes to feathers on face, nape and rump. In race *subtropicalis*, male similar but with nape more bronzy, less violet on back, and tail shorter and less forked, while female has paler grey belly; these tendencies further accentuated in *verticeps*; in race *hypochlora* male has belly mostly green with little violet, female uniform pale grey below.

Habitat. Humid forest and adjacent edges, tall second growth and semi-open habitats (cacao plantations, shaded gardens), avoids open, scrubby areas; in forest occurs from understorey to lower part of canopy. Breeds from sea-level locally to 1200 m on the Pacific slope, and at 800-1900 m on the slopes of the Cauca Valley in Colombia.

Food and Feeding. As far as known, visits a similar range of flowers as *T. colombica*, including those of epiphytes (especially bromeliads, Ericaceae and mistletoes), shrubs and mostly small trees (*Besleria*, *Hamelia*, *Cephaelis*, *Palicourea*, *Aphelandra*, *Inga*), large herbs like *Heliconia* and *Costus*; prefers flowers under partial to closed canopy rather than in open; males notably aggressive and frequently territorial at rich clumps of flowers. Frequently flycatches by sallying from perch in canopy or along edge or gap, also (especially female) gleans arthropods off foliage.

Breeding. Feb-Sept in NW Colombia, Jan-Nov in SW Colombia. Nest a downy cup saddled on slender fork or twig 1-3 m (occasionally to 8 m) up in tall grass or shrubbery at forest edge or inside forest. Male may defend rich clumps of flowers to attract females. Clutch size 2. No further information.

Movements. No information available.

Status and Conservation. Not globally threatened. CITES II. Common to abundant in forested parts of Pacific slope of Colombia; more local and less numerous on slopes overlooking Cauca Valley, but able to use disturbed or fragmented forest in many areas. Severe deforestation of W Ecuadorian lowlands may well threaten the distinctive race *hypochlora*, on which more information is urgently required.

Bibliography. Becker & López (1997), Bertin & Wilzbach (1979), Best *et al.* (1997), Chapman (1926), Cook (1996), Escalante & Peterson (1992), Hilty (1997), Hilty & Brown (1986), Kirwan & Marlow (1996), Meyer de Schauensee (1949), Parker *et al.* (1995), Pople *et al.* (1997), Ridgely & Gwynne (1989), Robbins & Ridgely (1990), Salaman & Mazariegos (1998b), Stotz *et al.* (1996), Wetmore (1968a), Williams & Tobias (1994).

116. Fork-tailed Woodnymph

Thalurania furcata

French: Dryade à queue fourchée **German:** Schwalbennympe **Spanish:** Zafiro Golondrina
Other common names: Princess/Common/Cayenne Woodnymph

Taxonomy. *Trochilus furcatus* J. F. Gmelin, 1788, Cayenne.

Forms a superspecies with *T. ridgwayi*, *T. colombica* and *T. fannyi*; species limits unclear, and all four have been considered conspecific. Alternatively, mostly dull-crowned and more green-backed forms are sometimes separated in present species from the other three lumped as another species with glittering crowns and more violet on back. Of the races currently recognized, most are based on variations in coloration of adult male, and several doubtfully valid. Races *baeri* and *eriphile*, with glittering green frontlets, were in past separated as *T. eriphile*, but former intergrades with adjacent dull-crowned races in Brazil, indicating potential pitfalls of attributing taxonomic significance to this feature. Race *jelskii* represents zone of intergradation of *viridipectus*, *simoni* and *boliviana*; *furcatoides* intergrades with *balzani* and *baeri* where their ranges meet in NC & C Brazil. "*Thalurania lerchi*", known from Bogotá trade skins, is apparently a hybrid between present species and *Chrysoronia oenone*; "*Eucephala scapularia*", known from single specimen from French Guiana, is probably a hybrid of present species with *Chlorostilbon notatus*. Name *tschudii* should perhaps replace *jelskii*; if so, *jelskii* may be correct name for current race *boliviana*. Proposed race *taczanowskii* (NE Peru) not reliably separable from *viridipectus*. Thirteen subspecies recognized.

Subspecies and Distribution.

T. f. refulgens Gould, 1853 - NE Venezuela; erroneously reported from Trinidad.
T. f. furcata (J. F. Gmelin, 1788) - extreme E Venezuela, the Guianas and NE Brazil (N of Amazon).
T. f. fissilis Berlepsch & Hartert, 1902 - E Venezuela and adjacent extreme W Guyana and NE Brazil.
T. f. orenocensis Hellmayr, 1921 - upper Orinoco region of S Venezuela.
T. f. nigrofasciata (Gould, 1846) - SE Colombia, NW Brazil (upper R Negro) and extreme S Venezuela.
T. f. viridipectus Gould, 1848 - E foothills of Andes and adjacent lowlands of E Colombia, E Ecuador and NE Peru.
T. f. jelskii Taczanowski, 1860 - most of E Peru and adjacent Brazil.
T. f. simoni Hellmayr, 1906 - upper Amazon region (S of Amazon) in extreme E Peru and W Brazil.
T. f. balzani Simon, 1896 - NC Brazil (S of Amazon).
T. f. furcatoides Gould, 1861 - lower Amazon region of E Brazil (S of Amazon).
T. f. boliviana Boucard, 1894 - Andean foothills and adjacent lowlands of SE Peru and NE Bolivia.
T. f. baeri Hellmayr, 1907 - NE & C Brazil to SE Bolivia and NW & NC Argentina.
T. f. eriphile (Lesson, 1832) - SE Brazil, adjacent Paraguay and NE Argentina (Misiones).

Descriptive notes. Male 9.5-10.5 cm, 4-8 g; female 8-9 cm, 4-2 g. Straight medium-sized bill black. Male mostly dark bronzy-green above with crown and nape dark dusky-bronze; throat is glittering green, the belly and a band across the upper back violet; tail blue-black and forked, undertail-coverts dark steely blue edged broadly with dull white. Female bright green above, duller and more bronze on the crown, and pale grey below; the distal part of the tail is steely blue-black, the outer 3 rectrices white-tipped. Immature male nearly uniform dusky bronze-green below and dull bronze-green above; immature female averages more bronzy-green

above than adults and usually shows some pale buffy fringes on face, nape and rump feathers. Race *fissilis* differs mainly in longer bill and (male) solid blue undertail-coverts; in *nigrofasciata* and *verticeps* band of violet across upper back interrupted medially, and green of throat more extensive and separated from violet belly by a band of black, usually broader in the former; *nigrofasciata* is more golden green, *verticeps* more bluish-green above; *viridipectus* has green of gorget extending onto breast, bordered narrowly below with black; *jelskii* has lower throat and breast more or less tinged with blue and black band usually interrupted, basically representing an intergradation towards *boliviana*, in which green is restricted to gorget and black reduced to lateral patches or lacking; *furcatoides* differs from nominate mainly in larger size and more blackish crown; *balzani* has crown green, undertail-coverts usually pure white; *simoni* represents a zone of intergradation between *balzani* and *jelskii*-*boliviana*, being most like former but with dark central stripe on vent and undertail-coverts; *baeri* and *eriphile* have glittering green frontlets contrasting with blackish crowns, the former intergrading with the adjacent *furcatoides* and *balzani* where their ranges meet. Racial variation in females involves darkness of grey underparts, with some variation in lateral green scaling, colour and pattern of undertail-coverts, colour of crown and shade of green above, in general paralleling variations in their respective males.

Habitat. Humid forest (both *terra firme* forest and *várzea* in Amazonia) and forest edge, taller second growth and semi-open, shaded plantations and gardens; possibly in more scrubby habitats in some parts of range but more detailed information lacking.

Food and Feeding. Visits flowers of epiphytes (bromeliads, ericads), vines (*Mucuna*, *Gurania*), lianas (*Combretum*), trees (*Inga*, *Erythrina*, *Genipa*, *Tachigali*, *Quararibea*, *Syzgium*), shrubs (especially Rubiaceae, Acanthaceae) and large herbs (*Heliconia*, *Costus*) in forest and edge habitats in E Colombia; also obtains arthropods by flycatching and, less often, foliage-gleaning. Small flies and wasps important in diet with smaller numbers of ants, other insects and spiders.

Breeding. Birds in breeding condition recorded Apr-Oct in foothills of E Andes, Aug-Oct along the Amazon in E Colombia (*viridipectus*). No further information.

Movements. No information available; presumably more or less sedentary except for local movements following shifts in flowering; populations in Andean foothills may move altitudinally.

Status and Conservation. Not globally threatened. CITES II. Common over most of its wide range but populations in some areas are or may soon be threatened by deforestation, especially parts of Brazil, Colombia and Paraguay. In Brazil, occurs in several protected areas, e.g. Serra dos Órgãos and Brasília National Parks.

Bibliography. Blake (1950b), Bond & Meyer de Schauensee (1943), Butler (1979), Canevari *et al.* (1991), Chubb (1910), Cintra & Yamashita (1990), Contreras & Contreras (1990), Contreras *et al.* (1990), Cory (1918), Cotton (1993, 1998a), Friedmann (1948), Gilliard (1941), Grantsau (1988), Gyldestolpe (1945b), Hartert (1922), Haverschmidt & Mees (1994), Hayes (1995), Hellmayr (1908, 1929), Hilty & Brown (1986), Marini *et al.* (1997), Meyer de Schauensee & Phelps (1978), Olrog (1963c), Oniki (1996), de la Peña (1994), Perry *et al.* (1997), Phelps & Phelps (1958), Pinto (1947), Reimser & Traylor (1989), Ruschi (1981-1982, 1986), Rutgers & Norris (1972), Saibene *et al.* (1996), Short (1975), Sick (1993, 1997), Sneathale (1907, 1909, 1913), Snyder (1966), Stotz *et al.* (1996), Stouffer & Bierregaard (1995), Tostain *et al.* (1992), Willard *et al.* (1991), Willis (1992), Zimmer (1950c).

117. Long-tailed Woodnymph

Thalurania watertonii

French: Dryade de Waterton **German:** Langschwanznympe **Spanish:** Zafiro Colilargo
Other common names: Waterton's Woodnymph

Taxonomy. *Trochilus Watertonii* Bourcier, 1847, Miribi Creek, near Essequibo River, Guyana. Forms a superspecies with *T. glaucopsis*; probably old elements within genus *Thalurania*. Monotypic.
Distribution. E Brazil (E Pará to Pernambuco and Bahia); possibly also Guyana, where known only from type specimen.

Descriptive notes. Male c. 13 cm (including tail of 6 cm), female c. 10 cm; 4-6.5 g. Male has medium-sized straight bill, black; crown and lower neck green, back iridescent violet-blue; underparts shining grass green, flanks violet-blue; tail long, deeply forked, steel blue. Female has crown and hind neck golden green, lower back bluish-green; uniformly greyish-white below; tail not elongated, slightly forked, central pair of rectrices blue-green, rest green with broad, steel blue subterminal band and white tips. Immature similar to adult female, duller grey below, head feathers with buffy fringes.

Habitat. Coastal rainforest, *cerrado*, semi-open clearings, plantations and parks, from sea-level to 500 m. Forages at low to medium heights, usually at the periphery of vegetation.

Food and Feeding. Nectar of flowering vines, cacti, epiphytes, shrubs and trees, such as Passifloraceae, Cactaceae, Bromeliaceae, Loranthaceae, Verbenaceae, Rubiaceae, Leguminosaceae. Sometimes individuals cling to long corollas while feeding. Insects are caught in the air by hawking. Male establishes feeding territories which are aggressively defended against intraspecific and interspecific intruders.

Breeding. Nov-Feb. Cup-shaped nest of fine rootlets and moss, held together by cobweb, is built on horizontal branch in shrub or small tree, usually protected by overhanging leaves, 1.5-2.5 m above ground. Clutch size 2; incubation 14-15 days, by female; chick darkish with two rows of buffy greyish dorsal down; fledging at c. 20 days. First breeding in second year.

Movements. Sedentary, some inland wandering during flowering season.

Status and Conservation. Not globally threatened. CITES II. Common throughout range; seems to accept man-made habitats where patches of forest or stands of scattered trees remain. Common on Brazilian side of Iguaçu Falls, with density of at least 2-3 pairs/km². Occurs in Monte Pascoal National Park, Bahia, and Pedra Talhada State Park, Alagoas.

Bibliography. Butler (1926a), Forrester (1993), Grantsau (1988), Meyer de Schauensee (1982), Pacheco & Whitney (1995), Pinto (1935), Ruschi (1981-1982, 1982a, 1986), Rutgers & Norris (1972), Sargeant (1996), Sick (1993, 1997), Snyder (1966), Stotz *et al.* (1996), Willis (1992).

118. Violet-capped Woodnymph

Thalurania glaucopsis

French: Dryade glaucope **German:** Blaukronennympe **Spanish:** Zafiro Capirotado
Other common names: Blue-crowned/Blue-headed/Brazilian Woodnymph

Taxonomy. *Trochilus glaucopsis* J. F. Gmelin, 1788, Brazil.

Forms a superspecies with *T. watertonii*; probably old elements within genus *Thalurania*. Monotypic.
Distribution. E & S Brazil (Bahia to Rio Grande do Sul), E Paraguay and NE Argentina; doubtfully N Uruguay.

Descriptive notes. 8-11 cm; male 5-0 g, female 4-0 g. Male has bill straight, medium-sized, almost blackish or with dark brown tip to lower mandible; cap glittering violet-blue; upperparts dark golden green; underparts brilliant green; undertail-coverts greenish to bluish, laterally greyish-brown; tail forked, steel blue. Female lacks contrasting cap; underparts including undertail-coverts dirty white to pale buff; tail only slightly forked; inner rectrices metallic green, outer rectrices steel blue with whitish tips. Immature male has turquoise-blue cap, with or without scattered violet-blue feathers; throat feathers with whitish subterminal

bars; greyish-brown areas on breast, belly and undertail-coverts.

Habitat. Virgin forest, forest edges, scrub; also found in suburban areas like parks and gardens, and even within city centres. Ranges from near sea-level to 850 m.

Food and Feeding. Forages for nectar at a great variety of native and introduced plants. In forested areas, plant families include epiphytes like Bromeliaceae (*Vriesea*), Orchidaceae, Marantaceae, Musaceae, Passifloraceae, Leguminosae (*Dahlstedtia*), Zingiberaceae, Rubiaceae, Bombacaceae, Vochysiaceae, Strelitziaceae, *Heliconia*; in gardens, Malvaceae (*Hibiscus*, *Abutilon*), Euphorbiaceae (*Poinsettia*), Crassulaceae (*Kalanchoe*), Fabaceae (*Erythrina*); various tree species, including *Citrus*, *Anacardium*, *Dombeya* and *Eucalyptus*. Feeds also on small insects that are caught by gleaning or hawking.

Breeding. Oct-Feb. Nest bowl-shaped, made of soft plant wool and fibres, such as Gramineae, *Typha*, Bombacaceae, or Bromeliaceae; external "decoration" includes fern scales and lichen; placed on a horizontal branch or in twig fork in tree such as *Chusquea*, 1.5-3 m above ground. Clutch size 2; incubation 15 days, by female; fledging period 20-25 days.

Movements. Short-distance migrant. Although sometimes listed for Uruguay, no recent confirmation of breeding, leaving southern limits of distribution unclear; perhaps only occurs as migrant.

Status and Conservation. Not globally threatened. CITES II. One of commonest trochilids in SE Brazil, where frequent both in forested and semi-open areas; occurs in several protected areas, e.g. Serra dos Órgãos and Itatiaia National Parks. In Paraguay, known only from Alto Paraná region; in Argentina, found in humid lowlands of Misiones.

Bibliography. Belton (1984), Berlioz (1930a, 1931a, 1934, 1964, 1965), Brooks *et al.* (1993), Canevari *et al.* (1991), Forrester (1993), Grantsau (1988), Guix *et al.* (1992), Hayes (1995), Laubmann (1940), Lowen, Bartrina, Clay & Tobias (1996), Lowen, Clay *et al.* (1995), Marini *et al.* (1997), Naroosky & Yzurietta (1993), Navas & Bo (1993), Oniki (1996), Parker & Goerck (1997), de la Peña (1994), do Rosário (1996), Ruschi (1949b, 1973d, 1976d, 1981-1982, 1986), Rutgers & Norris (1972), Saibene *et al.* (1996), Sargeant (1996), Scott & Brooke (1985), Sick (1993, 1997), Sick & Teixeira (1981), Snow & Snow (1986), Sosa (1937), Stotz *et al.* (1996), Tobias *et al.* (1993), Willis (1992).

Genus *DAMOPHILA* Reichenbach, 1854

119. Violet-bellied Hummingbird

Damophila julie

French: Colibri julie **German:** Juliakolibri **Spanish:** Colibrí de Julia
Other common names: Julie's Hummingbird

Taxonomy. *Ornismya* [sic] *julie* Bourcier, 1842, Tunja, Colombia. Affinities unclear; genus possibly close to *Thalurania* or *Chlorostilbon*. Three subspecies recognized. **Subspecies and Distribution.**

D. j. panamensis Berlepsch, 1884 - C Panama (Canal Zone, both slopes of Darién); also reported, apparently in error, from Costa Rica.
D. j. julie (Bourcier, 1842) - N & C Colombia. E to Santa Marta, Magdalena Valley and Tolima.
D. j. feliciana (Lesson, 1844) - SW Colombia (Nariño) through W Ecuador to NW Peru (Tumbes).

Descriptive notes. 8.1-9.2 cm; male 3.3-3.5 g, female 2.5-3 g. Male has short straight bill, upper mandible black, lower pinkish, tipped black; iridescent green crown, back shining green; gorget glittering green, belly iridescent violet-blue; tail rounded, bluish-black. Female above similar to male, below greyish-white, outermost pair of rectrices tipped grey. Immature male like adult female, often with some blue spots on belly. Race *panamensis* has crown green like back; *feliciana* has longer bill, crown brilliant green, belly violet.

Habitat. Lowland forest, forest edge, second growth, clearings, common in semi-open forest, occasionally in canopy when trees are in flower. Sometimes participates in mixed species flocks.

Food and Feeding. Nectar of flowering shrubs and trees, including Rubiaceae, Ericaceae, Gesneriaceae (*Besleria*) and *Inga*. Insects are caught in the air by hawking. Male establishes territories at nectar-rich food sources.

Breeding. Jan-Jul (Panama), Nov-May (Colombia, Ecuador). Cup-shaped nest of plant down is saddled on small branches of bushes at 1.5-4.2 m above the ground. Clutch size 2; incubation c. 15 days, by female; chick has two rows of grey-buff dorsal down; fledging period 20-22 days.

Movements. Sedentary, with some seasonal altitudinal dispersal, usually after reproduction. **Status and Conservation.** Not globally threatened. CITES II. Widespread and fairly common in coastal lowlands. Some local populations protected, e.g. in Tayrona and Los Katíos National Parks (Colombia) and Río Palenque Science Centre (Ecuador). Until mid-1970's, species was common in international bird trade, but this has now ceased.

Bibliography. Anon. (1998a), Berg (1994), Best *et al.* (1997), Brosset (1964), Butler, A.L. (1928), Butler, T.Y. (1979), Darlington (1931), Gloger (1987), Hallinan (1924), Hilty & Brown (1986), Parker, Parker & Plenge (1982), Parker, Schulenberg *et al.* (1995), Pople *et al.* (1997), Ridgely & Gwynne (1989), Rousseau-Decelle (1931), Slud (1964), Stiles & Skutch (1989), Stotz *et al.* (1996), Wetmore (1968a), Williams & Tobias (1994), Willis & Eisenmann (1979).

Genus *LEPIDOPYGA* Reichenbach, 1855

120. Sapphire-throated Hummingbird

Lepidopyga coeruleogularis

French: Colibri faux-saphir **German:** Blaukehlkolibri **Spanish:** Colibrí Gorgizafiro
Other common names: Duchassain's Hummingbird

Taxonomy. *Trochilus* (—?) *coeruleogularis* Gould, 1851, David, Chiriquí, Panama. Closely related to *Damophila*, and sometimes placed therein. *L. lilliae* sometimes considered a race, morph or age stage of present species. Race *confinis* occasionally considered synonymous with nominate. Three subspecies recognized.

Subspecies and Distribution.
L. c. coeruleogularis (Gould, 1851) - Pacific slope of W Panama from Chiriquí to Canal Zone.
L. c. confinis Griscom, 1932 - E Panama (Caribbean slope of Darién) and adjacent NW Colombia.
L. c. coelina (Bourcier, 1856) - N Colombia, from N Chocó through Ciénaga Grande to Santa Marta.

Descriptive notes. 8.5-9.5 cm; 3.9-4.3 g. Male has straight short bill, upper mandible black, lower pinkish, tipped black; upperparts shining green, coppery on rump; throat and chest iridescent violet-blue, rest of underparts glittering green; tail forked, central rectrices coppery gold, rest blue-black. Female similar to male but greyish-white below, bluish-green spots on sides, outer rectrices tipped white. Immature like adult female, buffy fringes on head feathers. Race *confinis* darker green on upper back, with chin and throat glittering turquoise; *coelina* less bronzy above, with blue throat.

Habitat. Shrubby vegetation, open groves, forest edge, mangroves, coastal lowland up to 100 m in Santa Marta, N Colombia. Usually forages rather low down inside semi-open shrub habitat; may also be seen in canopy when trees are in flower.

Food and Feeding. Nectar of flowering shrubs and trees like Leguminosaceae and Myrtaceae. Arthropods are gleaned from branches and leaves, and occasionally flying insects are caught by hawking. During peak of blooming season several individuals may be seen together in flowering trees.

Breeding. Jan-Mar (Panama, N Colombia), but nests have also been found in Jul (Colombia). Small deeply-cupped nest is built openly in forks of low shrubs, of dry light-coloured plant down, externally decorated with lichen and pieces of dead leaves, c. 0.7-1.5 m above the ground. Clutch size 2; incubation 15-16 days, by female; chick is flesh-coloured with two rows of cinnamon dorsal down; fledging period 19-22 days.

Movements. Sedentary; local altitudinal dispersal likely to occur. **Status and Conservation.** Not globally threatened. CITES II. Common resident in coastal Darién (Panama) and Santa Marta region (Colombia). Readily accepts man-made habitats. Part of range protected, e.g. in Los Katíos and Tayrona National Parks (Colombia). **Bibliography.** Anon. (1998a), Griscom (1932b), Hilty & Brown (1986), Meyer de Schauensee (1982), Olrog (1968), Olson (1997), Ridgely & Gwynne (1989), Rodríguez (1982), Slud (1964), Stiles & Skutch (1989), Stotz *et al.* (1996), Wetmore (1968a), Willis & Eisenmann (1979).

121. Sapphire-bellied Hummingbird

Lepidopyga lilliae

French: Colibri de Lilliane **German:** Blaubauchkolibri **Spanish:** Colibri Ventrifaziro

Taxonomy. *Lepidopyga lilliae* Stone, 1917, Punto Caimán, Santa Marta, Colombia. Status uncertain: sometimes considered a race, morph or age stage of *L. coeruleogularis*. Monotypic. **Distribution.** Coastal NC Colombia, around Ciénaga Grande and near mouth of R Ranchería, Riohacha (Guajira).

Descriptive notes. 8.9-9.4 cm; male 4-3 g. Male has short straight bill, upper mandible black, lower pinkish tipped black; upperparts blue-green, underparts rich blue with iridescent violet throat; tail deeply forked, blue-black. Female and immature unknown.

Habitat. Occupies coastal mangroves, though also occasionally seen in xerophytic shrub vegetation. Mainly seen alone at various heights within mangroves.

Food and Feeding. Not known; most likely nectar and insects as other hummingbirds. **Breeding.** No information.

Movements. Unknown, most likely sedentary.

Status and Conservation. CRITICALLY ENDANGERED. CITES II. Restricted-range species; present in Caribbean Colombia and Venezuela EBA. A rare species endemic to N Colombian mangrove swamps, a habitat destroyed on large scale since 1970's by coastal highway and pipeline construction, leading to disruption of tidal flow. Species occurs within two major protected areas: Isla de Salamanca National Park (21,000 ha) and Ciénaga Grande de Santa Marta Sanctuary (23,000 ha). Research and survey work required before adequate protective measures can be taken.

Bibliography. Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Darlington (1931), Franky & Rodríguez (1977), Goehfeld *et al.* (1980), Hilty & Brown (1986), Meyer de Schauensee (1949, 1966), Paynter & Traylor (1981), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Todd & Cumker (1922), Wege & Long (1995).

122. Shining-green Hummingbird

Lepidopyga goudoti

French: Colibri de Goudot **German:** Grünkolibri **Spanish:** Colibrí de Goudot
Other common names: Luminous Hummingbird (*luminosa*)

Taxonomy. *Trochilus Goudoti* Bourcier, 1843, Ibagué, Magdalena Valley, Colombia. Race *luminosa* (perhaps including *phaeochroa*) has sometimes been treated as a separate species. Four subspecies recognized.

Subspecies and Distribution.
L. g. luminosa (Lawrence, 1862) - coastal lowlands of N Colombia.
L. g. goudoti (Bourcier, 1843) - middle and upper Magdalena Valley (C Colombia).
L. g. zuliae Cory, 1918 - N & W parts of L Maracaibo basin (extreme NE Colombia and NW Venezuela).
L. g. phaeochroa Todd, 1942 - S & E parts of L Maracaibo basin (NW Venezuela).

Descriptive notes. 9.9-5 cm; male 4.1 g, female 3.7 g. Straightish bill black, with lower mandible mainly pink. Male green above; tail forked, central rectrices bronze-black, lateral rectrices blue-black; most of underparts shining bluish-green, belly whitish, undertail-coverts green with whitish borders. Female resembles male, differing in having broad whitish bases and fringes on underparts, which give a spotty appearance to the lower breast, passing to a nearly pure white belly; undertail-coverts mostly white with green centres, tail less deeply forked than male and less black, more bronzy to greenish. Immature dull bronzy-green below, feathers with prominent greyish-white fringes, passing to greyish-white on belly; duller green above with narrow dusky fringes on feathers of crown and nape. In race *luminosa* male less bluish, more golden green below, more bronzy above, female with less white on belly and undertail-coverts; *zuliae* smaller, crown darker, upperparts less bronzy, undertail-coverts with only narrow whitish borders; *phaeochroa* darker above and bluer on crown, male more bluish-green below.

Habitat. Open, brushy country with scattered trees, hedgerows and scrubby pastures, arid to moist scrub, borders of gallery forest, light woodland, coffee plantations, gardens. From sea-level to 1000 m, occasionally to 1600 m (Colombia); to 800 m in Venezuela.

Food and Feeding. Visits flowers of a variety of shrubs and trees, especially those of legumes like *Inga*, *Calliandra* and *Pithecellobium saman*; sometimes many gather in noisy, quarrelsome assemblages at flowering trees. Along streams, may visit flowers of *Heliconia*, in gardens cultivated *Hibiscus*, etc. Flycatches from exposed perches atop shrubs or small trees, and gleans arthropods from twigs, branches and foliage in tree crowns.

Breeding. Oct-Mar; nest a small cup of pale-coloured plant down and cobwebs, decorated on outside with whitish lichens, on horizontal outer branch of shrub or small tree adjoining open area, 1-1.5 m above ground (*goudoti*). No further information.

Movements. Presumably sedentary; local altitudinal dispersal likely to occur, as perhaps indicated by apparent seasonal changes in abundance in Santa Marta area and S Huila (Colombia).

Status and Conservation. Not globally threatened. CITES II. Locally common over much of range, which has probably expanded in many areas with deforestation. Occurs in Tayrona National Park (NE Colombia). Frequently recorded between San Carlos de Zulía and Encontrados (NW Venezuela).

Bibliography. Cory (1918), Hilty & Brown (1986), Meyer de Schauensee (1982), Meyer de Schauensee & Phelps (1978), Miller (1947, 1952), Olrog (1968), Peña, M. (1997), Phelps & Phelps (1958), Stotz *et al.* (1996), Todd (1942).

Genus *HYLOCHARIS* Boie, 1831

123. Blue-throated Goldentail

Hylocharis eliciae

French: Saphir d'Elicia **German:** Goldschwanz-Saphirkolibri **Spanish:** Zafiro de Elicia
Other common names: Blue-throated Sapphire

Taxonomy. *Trochilus Eliciae* Bourcier and Mulsant, 1846, no locality = Cobán, Alta Vera Paz, Guatemala.

Two subspecies recognized.

Subspecies and Distribution.

H. e. eliciae (Bourcier & Mulsant, 1846) - SE Mexico and Belize patchily S to S Costa Rica.

H. e. earina Wetmore, 1967 - W Panama, including Coiba I and islands in Bay of Panama, to extreme NW Colombia.

Descriptive notes. 9 cm; male 4.1 g, female 3.6 g. Upper and lower mandible of male bill red with black tip, that of female with culmen and tip black; feet dark grey. Male bronzy-green above, darkest on crown, shading to purplish-bronze on uppertail-coverts and golden bronze on tail; throat and chest purplish-blue, lower breast and sides green, belly greyish-buff. Female like male above, mostly dull buffy below, passing to green laterally; throat and breast spotted with blue. Immature has very little blue, veiled by broad greyish-buff feather fringes, and tail is much duller bronze; upper mandible often mostly greyish to blackish. Race *earina*

is darker above, with the tail duller, more greenish-bronze.

Habitat. In humid areas prefers forest edge, tall second growth, semi-open, light woodland, gardens and hedgerows; in drier areas most numerous in evergreen gallery forest, often entering open areas to feed at flowers. Lowlands locally to 750-1000 m.

Food and Feeding. Visits flowers of shrubs (*Stachytarpheta*, *Hamelia*), large herbs (*Heliconia*, *Renalmia*, *Thalea*), trees (*Inga*, *Pisidium*) and epiphytes like bromeliads in openings and along forest borders, usually near ground but sometimes to lower canopy; flycatches and gleans arthropods from foliage.

Breeding. Dry season, Dec-Apr. During breeding season male sings thin, piercing song of variable phrases of 5-8 notes from perches on horizontal twigs in upper understory or lower canopy, in leks of up to 10. Nest a cup with strongly incurved rim, of fine plant fibres, down and cobwebs, sparsely decorated with bits of lichen. 2-6 m up on horizontal twig in second growth, gallery forest or garden. Clutch size 2. No further information.

Movements. Little information; presumably more or less sedentary except for local wanderings during flowering.

Status and Conservation. Not globally threatened. CITES II. Uncommon to locally common, freely entering open or disturbed areas; has probably increased in some areas, following forest clearance; may disappear locally when vegetation grows too tall and dense.

Bibliography. Binford (1989), Brown & Bowers (1985), Carriker (1910), Dickey & van Rossem (1938), Eisenmann (1952), Feinsinger (1976, 1980), Fogden (1993), Friedmann *et al.* (1950), Hilty & Brown (1986), Howell & Webb (1995a), Johnsgard (1997), Land (1970), Mills & Rogers (1988), Monroe (1968), Olson (1997), Ridgely & Gwynne (1989), Ridgway (1911), Rodríguez (1978), Salaman & Mazariegos (1998b), Skutch (1972), Slud (1960, 1964, 1980), Stiles (1980, 1985b, 1985c), Stiles & Skutch (1989), Stone (1932), Stotz *et al.* (1996), Thurber *et al.* (1987), Vallely & Aversa (1997), Wetmore (1957a, 1968a), Willis & Eisenmann (1979).

124. Rufous-throated Sapphire

Hylocharis sapphirina

French: Saphir à gorge rousse **German:** Rotkehl-Saphirkolibri **Spanish:** Zafiro Gorgirrojo
Other common names: Red-throated Sapphire

Taxonomy. *Trochilus sapphirinus* J. F. Gmelin, 1788, the Guianas.

In past, several races were recognized, notably *guianensis* (Guyana) and *brasilensis* (Bahia), but pattern of distinguishing morphological characters is not constant. Monotypic.

Distribution. E Colombia (Vaupés, Amazonas), S Venezuela (Amazonas, Bolívar) and the Guianas to E Ecuador, NE Peru and NW & NC Brazil (Amazonas E to Amapá and Pará); also NE Bolivia (NE Santa Cruz), Paraguay and C & E Brazil (Bahia S to São Paulo) to NE Argentina (Chaco, Formosa, Misiones).

Descriptive notes. 8.4-8.9 cm; male 4.1-4.5 g, female 3.9-4.3 g. Male has medium-sized straight bill, coral red, tipped black; upperparts dark green, uppertail-coverts coppery violet; chin intensely rufous, throat and chest iridescent violet-blue, undertail-coverts chestnut; central rectrices coppery tinged violet, rest chestnut, tipped dusky grey. Female similar to male above, chin pale rufous, underparts greyish with large glittering blue-green discs on throat and chest; undertail coverts buffy, tail as in male, outer rectrices with paler edges. Immature similar to adult female; young male with rich rufous on chin.

Habitat. Forest edge, savanna with scattered bushes and stands of trees, clearings around granite outcrops, coffee plantations, more rarely in open coastal vegetation. Most numerous around 200-500 m, sometimes found at higher elevations up to 1800 m. Forages from low down to medium height on the periphery of vegetation.

Food and Feeding. Nectar of flowering shrubs, small trees, vines and epiphytes, including Leguminosae, Rutaceae, Rubiaceae, Myrtaceae, Loranaceae, Passifloraceae and Bromeliaceae. Usually seen feeding from near the ground to lower strata; in Amazonia, during flowering period,

regular visitor to tree tops. Insects are caught in the air by hawking, spiders gleaned from the surface of leaves or from webs. Male establishes feeding territories, defending them aggressively against intruders.

Breeding. Jul-Jan (the Guianas), Aug-Feb (Brazil). Cup-shaped nest of plant fibre, lined with soft seed-down, sometimes decorated on outer wall with lichen and parts of leaves, is placed on horizontal branch of shrub and tree, protected by overhanging leaves, at 4-6 (3-10) m above the ground. Clutch size 2; incubation 14-16 days, by female; chick blackish with sparse buffy dorsal down; fledging period 22-27 days.

Movements. Sedentary, migratory in parts of SE Brazil. Migration pattern is poorly documented.

Status and Conservation. Not globally threatened. CITES II. A common species in most of range; densities of at least 3-4 pairs/km² in the Voltzberg area of C Surinam. Until recently, presence in Paraguay was considered doubtful, but several sightings during 1990's, e.g. in Caaguazú National Park (Canindeyú). Accepts man-made habitats like coffee plantations, if bordered by natural, semi-open habitats.

Bibliography. Bangs & Penard (1918), Best *et al.* (1997), Brooks, Barnes *et al.* (1993), Brooks, Clay *et al.* (1995), Butler (1979), Canevari *et al.* (1991), Cintra & Yamashta (1990), Contreras *et al.* (1990), Friedmann (1948), Gilliard (1941), Grantsau (1988), Haverschmidt & Mees (1994), Hayes (1995), Hilty & Brown (1986), Lowen, Bartrina, Clay & Tobias (1996), Lowen, Clay *et al.* (1997), Meyer de Schauensee & Phelps (1978), Nores *et al.* (1983), Oniki (1996), Parker *et al.* (1982), de la Peña (1994), Remsen & Traylor (1989), do Rosário (1996), Ruschi (1967a, 1973d, 1981-1982, 1982a, 1986), Rutgers & Norris (1972), Short (1975), Sick (1993, 1997), Snyder (1966), Stotz *et al.* (1996), Tostain *et al.* (1992), Zimmer (1950e).

125. White-chinned Sapphire

Hylocharis cyanus

French: Saphir azuré **German:** Weißkinn-Saphirkolibri **Spanish:** Zafiro Gorgiblancos

Taxonomy. *Trochilus cyanus* Vieillot, 1818, Rio de Janeiro, Brazil.

Species name has alternatively been given as *cyana* or *cyanea*, but original name is a Greek noun, and is not variable. "*H. pyropygia*" is probably a hybrid of present species and *Chlorostilbon aureoventris pucherani*; "*Chlorostilbon hypocyaneus*", known only from two trade skins from Bahia, may be a hybrid of present species with *Chlorostilbon notatus*, or a mutant of that species, or possibly even a valid species. Five subspecies recognized.

Subspecies and Distribution.

H. c. viridiventris Berlepsch, 1880 - N & E Colombia, W & S Venezuela and the Guianas to N Brazil (to Mato Grosso and Maranhão).

H. c. rostrata Boucard, 1895 - E Peru, NE Bolivia and W Brazil (Mato Grosso); probably E Ecuador.

H. c. conversa Zimmer, 1950 - E Bolivia, N Paraguay and SW Brazil (Mato Grosso do Sul).

H. c. cyanus (Vieillot, 1818) - coastal E Brazil (Pernambuco to Rio de Janeiro).

H. c. griseiventris Grantsau, 1988 - coastal SE Brazil (São Paulo) and NE Argentina (Buenos Aires).

Descriptive notes. 8.9 cm; 3.5 g. Male has bill straight, medium-sized, coral red except for dark tip, or with darker upper mandible: forehead, crown, cheeks, throat brilliant violet-blue, sometimes extending to neck; upperparts golden green, becoming copperish towards rump; chin feathers basally whitish; sides of neck and lower throat bluish; belly and flanks golden green, centre towards belly more greyish; uppertail-coverts deep copperish to purple; undertail-coverts dark bronze-green to copperish or purplish; tail steel blue to bluish-black, median rectrices sometimes deep bronze-green. Female lacks violet-blue head

and throat; upperparts lighter golden green, less contrasting rump, centre of underparts greyish; undertail-coverts white, outer rectrices with grey terminal band. Immature male has head and throat partially bluish-green; belly greyer, undertail-coverts dark greyish. Race *viridiventris* has shorter bill, male has belly darker emerald to bluish-green, and undertail-coverts steel blue to dark purple, whereas female has belly and undertail-coverts partially marked with dark grey; *rostrata* larger in all morphometric characters; *conversa* has longer bill, with belly and undertail-coverts in male paler green to greyish, the latter more strongly margined; male *griseiventris* has crown and throat bluish-green, belly greyish, lower rump generally more coppery to wine red.

Habitat. Inhabits edges of tropical lowland evergreen forests, gallery forests, riparian woodland, clearings with scattered trees, plantations, *capoeiras*; in Amazonia and SE Brazil, also occurs in white sand forests and *restinga*. Ranges from lowlands to sub-montane zone, between 200 and 1000 m; in SE Brazil, close to sea-level.

Food and Feeding. Forages for nectar of various plant species, including Verbenaceae, Loranaceae, Malvaceae, Leguminosae, Myrtaceae, Rutaceae, Convolvulaceae, Rubiaceae, Acanthaceae, Vochysiaceae and Bromeliaceae. Diet also includes spiders, beetles and flies (Diptera). Feeds at all heights from ground to tree tops, sometimes gathering at feeding trees.

Breeding. Almost all year round. Nest cup-like, made of plant fibres, built on a horizontal branch, 1.5-4 m above ground; cobweb and lichen attached to outer wall. Clutch size 2; incubation 14-15 days, by female; fledging at 20-26 days.

Movements. Some local dispersal, especially in eastern parts of range.

Status and Conservation. Not globally threatened. CITES II. Fairly common in more humid areas along forest borders and in riparian woodland; less common in more arid habitats. Accepts man-made habitats, e.g. fruit plantations and parks. Occurs in a considerable number of protected areas, such as Amacayacu National Park (Colombia), Imataca Forest Reserve (Venezuela) and Tambopata Reserve (Peru).

Green-and-white Hummingbird (*Leucippus viridicauda*); 139. Many-spotted Hummingbird (*Leucippus hypostictus*).

Bibliography. Bangs & Penard (1918), Berlioz (1929a, 1938), Best *et al.* (1997), Bond & Meyer de Schauensee (1943), Butler (1979), Canevari *et al.* (1991), Collar *et al.* (1992), Dabbene (1926), Davis (1993), Donahue (1994), Grantsau (1988), Haverschmidt (1955a), Haverschmidt & Mees (1994), Friedmann (1948), Gilliard (1941), Hilty & Brown (1986), Mayr (1971), Meyer de Schauensee (1949, 1964), Meyer de Schauensee & Phelps (1978), Oniki (1996), de la Peña (1994), Perry *et al.* (1997), Pinto (1938), Remsen & Taylor (1989), Remsen, Taylor & Parkes (1986), Ruschi (1949b, 1981-1982, 1986), Rutgers & Norris (1972), Sánchez (1995), Sick (1993, 1997), Snyder (1966), Stotz *et al.* (1996), Taczanowski (1884), Terborgh *et al.* (1984), Tostain *et al.* (1992), Wege & Long (1995), Weller & Schuchmann (1997), Wetmore & Phelps (1956), Zimmer (1950e).

126. Gilded Hummingbird

Hylocharis chrysura

French: Saphir à queue d'or **German:** Goldsaphirkolibri **Spanish:** Zafiro Bronceado

Taxonomy. *Trochilus chrysurus* Shaw, 1812, Paraguay.

Some authors recognize a race *platensis* (S Brazil), but size differences and more intense coppery gold on underparts appear to refer to clinal variation. Monotypic.

Distribution. NE & SC Bolivia (Beni, Santa Cruz, Chuquisaca, Tarija), Paraguay and C & SE Brazil (Mato Grosso and Minas Gerais to São Paulo and Rio Grande do Sul) to Uruguay and N Argentina (S to Tucumán, Santiago del Estero, Santa Fe, Buenos Aires).

Descriptive notes. 8-10 cm; 4-4.6 g. Male has medium-sized straight bill, coral red, tipped black; above and below iridescent golden green, tiny white postocular spot, chin pale rufous, rectrices glittering golden bronze. Female similar to male, generally duller, lower belly greyish. Immature similar to adult female, head feathers fringed buff.

Habitat. Gardens, plantations, savannas with scattered bushes and trees, forest edges, from 200 to 1000 m, locally at higher elevations. Forages on the periphery of vegetation from low down to tree tops in clearings. Most numerous between 400 and 800 m.

Food and Feeding. Nectar of flowering native and introduced angiosperms, such as *Inga*, *Vochysia*, *Citrus*, *Eucalyptus*, *Hibiscus*, *Malvaviscus*, *Abutilon* and *Salvia*. Arthropods are caught in the air by hawking or are gleaned from vegetation surface. Collects small spiders from webs.

Breeding. Sept-Feb (Brazil). Small cup-shaped nest is built from seed fibres of *Asclepias*, *Chorisis* and various bromeliads, and cobweb, externally decorated with lichen and pieces of leaf; constructed on thin horizontal branch, rather exposed at height of 4-6 m, occasionally up to 12 m. Clutch size 2; incubation 14-15 days, by female; chick blackish with two dorsal rows of buffy down; fledging period 20-26 days. First breeding in second year.

Movements. Sedentary, migratory in parts of Brazil during Jul and Aug (Mato Grosso). Migration pattern poorly understood.

Status and Conservation. Not globally threatened. CITES II. A very common hummingbird throughout its range; readily takes to man-made habitats such as gardens and plantations. Due to its generalized habitat requirements range expansion can be expected.

Bibliography. Belton (1984), Bond & Meyer de Schauensee (1943), Brooks *et al.* (1993), Canevari *et al.* (1991), Cintra & Yamashita (1990), Contreras *et al.* (1990), Davis (1993), Fiameni (1991), Grantsau (1988), Klimaitis & Moschione (1987), Lowen, Barrina, Clay & Tobias (1996), Lowen, Clay *et al.* (1995), Motaldo (1984), Naumburg (1930), Navas & Bo (1993), Olog (1963c), Oniki (1996), de la Peña (1994), Pinto (1932), Pinto & de Camargo (1955), Remsen & Taylor (1989), Remsen, Taylor & Parkes (1986), do Rosário (1996), Ruschi (1973d, 1981-1982, 1982a, 1986), Saibene *et al.* (1996), Short (1975), Sick (1993, 1997), Stotz *et al.* (1996), Tobias *et al.* (1993), Wetmore (1926).

127. Blue-headed Sapphire

Hylocharis grayi

French: Saphir ulysse **German:** Blaukopf-Saphirkolibri **Spanish:** Zafiro Cabeciazul
Other common names: Gray's/Puritan Sapphire

Taxonomy. *Trochilus Grayi* DeLattre & Bourcier, 1846, Popayán, Colombia.

Formerly segregated in monospecific genus *Eucephala*. Races are so different in coloration, measurements and ecology that they should perhaps be considered separate species, probably forming a superspecies. Two subspecies currently recognized.

Subspecies and Distribution.

H. h. humboldtii (Bourcier & Mulsant, 1852) - extreme SE Panama to NW Ecuador.

H. h. grayi (DeLattre & Bourcier, 1846) - W Colombia and N Ecuador.

Descriptive notes. 10-11 cm; male 6.5-6.8 g, female 6.1-6.4 g. Bill of male mostly coral-red with black tip; upper mandible of female black tinged red basally, lower pinkish with black tip; feet blackish. Male of nominate has upper throat, face and crown deep glittering blue, nape dark blue-green, rest of underparts metallic green, forked tail dark steel blue; lower throat, breast and upper belly glittering emerald green, a small area of greyish-white on lower belly, undertail-coverts metallic green edged with dark grey. Female metallic green to bronze-green above; tail dark bronze-green basally, blue-black distally, outer rectrices

tipped greyish-white; below mostly greyish-white to dull white, sides of throat and breast extensively bronze-green, some bright green flecking across lower throat. Immature male lacks glittering blue or green on head and underparts; face and crown dull bluish-green, throat and breast bronzy-green, belly greyish-white, tail dusky grey at tip; immature female duller, more bronzy above and below. Race *humboldtii* has bill shorter on average, wings and tail longer. In male *humboldtii*, deep blue restricted to forehead and centre of throat, shading through blue-green to glittering green on chest, sides of neck, and malar area; sides green, most of belly and undertail-coverts white, the white typically extending forwards as a broad median stripe that ends abruptly on lower breast; crown dark dull blue-green, rest of upperparts metallic green to bronze-green, tail dark metallic green to blue, the outer rectrices more or less tipped dusky grey and narrow. Female

humboldtii averages much whiter below than nominate, heavily flecked with bright green on sides of throat and breast; crown bluer; tail metallic green to bronze-green, shading to dusky grey distally on lateral rectrices, which are more or less tipped pale grey. Immature male *humboldtii* more extensively white below than adults; medial throat and breast greyish flecked bronze, passing to bronze-green laterally; crown and face dull dark bluish-green.

Habitat. Nominat race occurs in dry scrub and woodland edges in dry, rain-shadow valleys of Pacific slope, also in cultivated areas, light woodland and forest borders in Andes, mostly at c. 500-2000, rarely 2600 m; *humboldtii* found along Pacific coast in mangroves and adjacent wet second growth, forest edges, mostly below 50 m, being commonest in areas where Pacific mangrove (*Pelliciera rhizophorae*) abundant. Few records of either race from intervening areas.

Food and Feeding. Nominat visits flowers of a variety of shrubs and trees, sometimes many gather in crowns of flowering trees where notably aggressive, sometimes defending feeding territories. Favourite flower of *humboldtii* is that of *Pelliciera*, but at times (perhaps seasonally) visits flowers of various shrubs, trees and large herbs like *Heliconia* in areas adjacent to mangroves. Both forms hawk flying insects from perches adjoining open areas or water, and glean small arthropods off foliage.

Breeding. Birds in breeding condition recorded Nov-Apr (*grayi*), Jan-May (*humboldtii*); nest undescribed. No further information.

Movements. Marked seasonal movements reported for *grayi*, which is erratic in most areas, but details lacking; no information for *humboldtii*.

Status and Conservation. Not globally threatened. CITES II. Cutting of mangroves for shrimp farming or firewood has doubtless resulted in much habitat loss for race *humboldtii* in some areas. Race *grayi* seems able to use more or less extensively altered, open or cultivated areas, though in Colombia, probably no longer occurs regularly in much of Cauca Valley, which has been converted to extensive rice and sunflower plantations; also, in Patía Valley, now found mostly in scattered remnants of natural vegetation.

Bibliography. Anon. (1998a), Best *et al.* (1997), Butler (1979), Chapman (1917, 1926), Fjeldsá & Krabbe (1990), Haffer (1986), Hilty & Brown (1986), Meyer de Schauensee (1949, 1982), Miller (1963), Negret (1992), Olog (1968), Ralph & Chaplins (1973), Ridgely & Gwynne (1989), Rutgers & Norris (1972), Stotz *et al.* (1996), Wetmore (1968a).

Genus *CHRYSURONIA* Bonaparte, 1850

128. Golden-tailed Sapphire

Chrysuronia oenone

French: Saphir oenone **German:** Bronzeschwanz-Saphirkolibri **Spanish:** Zafiro Colidorado

Taxonomy. *Ornismya aenone* Lesson, 1832, Trinidad; probably error = north-east Venezuela.

Monotypic genus, sometimes merged into *Hylocharis* because of similarity in plumage, but lacks swollen base of bill and enlarged nasal operculum of that genus. Proposed type locality of Trinidad seems unlikely, as there are apparently no definite records with specific localities, and the species is not mentioned in any work on Trinidad birds during present century. Race *alleni* may not be adequately separable from *josephinae*. Several other races proposed: *longirostris* from E Colombia differs from nominate only in average bill length; *azurea*, supposedly from W Ecuador but no definite records thence (in fact, probably from E Ecuador), has characters of a subadult male of *oenone*; *peruviana* doubtfully distinct from *josephinae*; and *intermedia* of upper Amazonia probably of hybrid origin. "Thalurania lerchii", known from Bogotá trade skins, is apparently a hybrid between present species and *Thalurania furcata*. Three subspecies currently recognized.

Subspecies and Distribution.

C. o. oenone (Lesson, 1832) - N & E Venezuela, E Colombia, E Ecuador, extreme NE Peru and adjacent extreme W Brazil.

C. o. josephinae (Bourcier & Mulsant, 1848) - most of E Peru.

C. o. alleni (Elliot, 1888) - N Bolivia.

Descriptive notes. 9.5-10 cm; male 4-7 g, female 4-3 g. Upper mandible black, lower red with black tip. Male has entire head and throat violet-blue, breast glittering green passing to bronzy-green on belly, undertail-coverts bronze edged with whitish; back bright green, shading through bronze-green to brilliant coppery upperside-coverts and copper-bronze tail. Female has crown blue, shading to green on back and copper-bronze on upperside-coverts and tail; below mostly whitish, heavily flecked with blue-green on sides of throat and neck, and green on sides and across chest, bronze-green on flanks; undertail-coverts with bronzy

centres. Immature male has crown dull green, throat dusky grey with dull buffy feather fringes and chest duller green; the first generation of blue feathers on the head and throat are more blue, less violet than in adult male; immature female has the green spotting below duller and more bronzy, less bluish than in adults. In race *josephinae*, male has throat mostly green, rump green contrasting more with coppery tail-coverts; *alleni* has no blue on throat and little or none on malar area, with rump more or less coppery in both sexes.

Habitat. Humid forest, especially at gaps and along edges, old second growth, gallery forest, semi-open areas like shaded cacao and coffee plantations, gardens and deciduous forest (Venezuela); mainly in foothills and adjacent lowlands, from sea-level to 1500 m (Colombia & Venezuela).

Food and Feeding. Visits mostly flowering trees (*Erythrina*, *Inga*) and shrubs (*Aphelandra*, *Palicourea*) for nectar; many may gather in quarrelsome assemblages at flowering trees, female more often trap-lines dispersed flowers in forest; male occasionally defends territories at flowers when more aggressive species like *Thalurania furcata* are absent; flycatches from perches at forest edge or gaps, and gleans arthropods from foliage.

Breeding. Birds in breeding condition Jun-Nov in E Colombia. During breeding season males usually in leks of 5-10, occasionally solitary. No further information.

Movements. Little information available; movements across Portachuelo Pass reported at Rancho Grande, Venezuela; presumably moves locally in response to shifts in flowering.

Status and Conservation. Not globally threatened. CITES II. Fairly common, at least locally, in foothill areas of Colombia and Venezuela, but relatively rare in Amazonian lowlands far from the Andes. In Colombia, known to use disturbed and fragmented forests.

Bibliography. Best *et al.* (1997), Blake (1962), Bloch *et al.* (1991), Bond & Meyer de Schauensee (1943), Butler (1979), Cotton (1998a), Donahue (1994), Grantsau (1988), Hilty & Brown (1986), Meyer de Schauensee & Phelps (1978), Mobbs (1972c), Parker *et al.* (1982), Remsen & Traylor (1989), Ruschi (1953a, 1986), Salaman & Mazariegos (1998a, 1998b), Schäfer & Phelps (1954), Sick (1993, 1997), Stotz *et al.* (1996), Terborgh *et al.* (1984), Wetmore (1939), Williams & Tobias (1994), Zimmer (1930, 1950c).

Genus *LEUCOCHLORIS* Reichenbach, 1854

129. White-throated Hummingbird

Leucochloris albicollis

French: Colibri à gorge blanche **German:** Weißkehlkolibri **Spanish:** Colibri Gargantilla
Other common names: Brazilian White-throated Hummingbird

Taxonomy. *Trochilus albicollis* Vieillot, 1818, São Paulo, Brazil.

"*L. malvina*", known only by type specimen from Rio de Janeiro, may be hybrid of present species and *Chlorostilbon aureoventris*. Monotypic.

Distribution. E Bolivia, E Paraguay, N Argentina and SE Brazil (Minas Gerais to Rio Grande do Sul); possibly also N Uruguay.

Descriptive notes. 10-11.5 cm; male 5.0 g, female 4.5 g. Male has bill straight, medium-sized, upper mandible blackish, lower flesh red with dark tip; upperparts golden to bronze-green; chin and throat brilliant green with white feather margins; cheeks and breast brilliant green to golden green; throat patch oval, white; flanks and belly golden to bronze-green; centre of belly white; undertail-coverts white, basally with bronze-green to brownish centres; uppertail-coverts and inner rectrices golden to brilliant green, lateral rectrices becoming blackish-green with white terminal bands. Female similar to male, but less glittering in plumage.

Immature has underparts more greyish-brown, less white; rectrices tipped brownish.

Habitat. Found along forest edges and in marshy habitats; also in open areas with scrub, or parks and gardens; from near sea-level to 1000 m.

Food and Feeding. Forages for nectar at various native and introduced plant species; often seen at Leguminosae (*Dahlstedtia*, *Inga*, *Dioclea*), Apocynaceae (*Mandevilla*), Acanthaceae (*Mendoncia*), Rubiaceae (*Manettia*), Lobeliaceae (*Lobelia*), Heliconiaceae, Agavaceae (*Phormium*), Bromeliaceae (*Nidularium*, *Vriesea*); also visits introduced plants, including *Citrus*, *Malvaviscus*, *Abutilon* and *Salvia*. Insects are caught by hawking.

Breeding. Oct-Mar. Nest cup-shaped, and consists of plant down and moss, externally decorated with lichens fixed with cobweb; built on horizontal branches of smaller trees and bushes. Clutch size 2; incubation 14 days, by female; fledging period 20-25 days.

Movements. Some local dispersal.

Status and Conservation. Not globally threatened. CITES II. Especially common in SE parts of range where widely adapted to man-made habitats. Range extension at SW limits of distribution; recent spread has been proven for Argentina, where now regularly occurs as breeder in provinces of Buenos Aires, Córdoba and Mar del Plata; additional records from E Bolivia. Current status and southern limits in Uruguay remain unclear.

Bibliography. de Almeida & Ruschi (1976), Belton (1984), Berlioz (1934, 1938), Berry (1989), Bo & Darrieu (1988), Brooks *et al.* (1993), Canevari *et al.* (1991), Contreras & Contreras (1990), Contreras *et al.* (1990), De Lucca (1990), Grantsau (1988), Hayes (1995), Lowen, Bartrina, Clay & Tobias (1996), Maragliano (1994), Montaldo (1984, 1995a), Narosky (1983), Narosky & Yzurietta (1993), Núñez (1992), Olrog (1963a), Oniki (1996), de la Peña (1994), Pereyra (1965), Pinto (1938, 1978), Roitman & Neumann (1995), do Rosário (1996), Ruschi (1949a, 1981-1982, 1982a, 1986), Rutgers & Norris (1972), Saibene *et al.* (1996), Sazima, I. *et al.* (1996), Sazima, M. *et al.* (1994), Sick (1993, 1997), Simon & Hellmayr (1908), Snow & Snow (1986), Snow & Teixeira (1982), Storer (1989), Stotz *et al.* (1996), Todd (1938), Wittmann (1982).

Genus *POLYTMUS* Brisson, 1760

130. White-tailed Goldenthrout

Polytmus guainumbi

French: Colibri guainumbi **German:** Bronzerücken-Glanzkehlchen **Spanish:** Colibri Guainumbi
Other common names: White-tailed Hummingbird(?)

Taxonomy. *Trochilus guainumbi* Pallas, 1764, Cape of Good Hope; error = Surinam.

Genus probably constitutes an old Guianan and C Brazilian element with close morphological and behavioural affinities with *Leucochloris* and *Leucippus*. In past, genus was considered monospecific, comprising present species only. Forms a superspecies with *P. milleri*. Name *andinus* was thought to be preoccupied and this taxon was thus renamed "*doctus*", but renaming unjustified. Three subspecies recognized.

Subspecies and Distribution.

P. g. andinus Simon, 1921 - E Colombia (S to Meta and Vichada).

P. g. guainumbi (Pallas, 1764) - Venezuela and Trinidad to the Guianas and N Brazil.

P. g. thaumantias (Linnaeus, 1766) - E Bolivia, E Paraguay and C & E Brazil (S Maranhão and Bahia to Mato Grosso do Sul, São Paulo and N Paraná) to NE Argentina.

Descriptive notes. 9.7-10 cm (including bill of 2.5 cm); 4.5-5 g. Male has long bill, decurved, upper mandible dull reddish to black, lower reddish, tipped black; upperparts shining golden to bronzy-green, dusky grey eye patch bordered above and below by long white streak; underparts

iridescent golden green; tail rounded, long, green, tipped white, broad white edges on outer 3 rectrices. Female similar to male but with buffy facial streaks; chin whitish, rest of underparts buff, throat and breast spotted green. Immature like adult female, head feathers fringed buff. Race *andinus* has more white on inner rectrices; *thaumantias* similar to nominate but bill shorter, upperparts reddish-golden, less white on outer tail feathers.

Habitat. Waterlogged grassland, shrubby savanna, *cerrado*, freshwater swamps, from sea-level to 600 m. Forages very close to ground; solitary.

Food and Feeding. Nectar of flowering garden plants such as *Lagerstroemia*, low-growing shrubs like *Russelia*, clumps of *Heliconia*, Leguminosae, Malvaceae, or Rubiaceae. Insects are caught in the air by hawking, spiders are gleaned from the surfaces of vegetation.

Breeding. Mar-Aug (Trinidad, Surinam), Feb-Apr and Jul-Sept (French Guiana), Oct-Nov (Venezuela), Oct-Mar (Brazil). Nest is cone-shaped cup of plant down (usually from *Typha*) decorated with lichen or seed, built in fork of small shrub, exposed, c. 0.5-1 m above ground, often over water; nests sometimes in close vicinity to each other. Clutch size 2; incubation 14-15 days, by female; chick black with sparse buffy dorsal down; fledging period 20-22 days.

Movements. Mostly sedentary; in Trinidad seasonal dispersal following reproduction.

Status and Conservation. Not globally threatened. CITES II. Common to locally abundant throughout most of range; rather uncommon and local on Trinidad. Habitats in many parts of range are not seriously threatened. Regularly recorded in Das Emas National Park, Goiás, and also in Pantanal of Mato Grosso (Brazil).

Bibliography. Baldo *et al.* (1995), Canevari *et al.* (1991), Cintra & Yamashita (1990), Contreras & Contreras (1990), Contreras *et al.* (1990), Costa & Bornschein (1995), Davis (1993), Esteban (1947), French (1991), Friedmann & Smith (1950), Gilliard (1941), Grantsau (1988), Hartert (1899b), Haverschmidt & Mees (1994), Hayes (1995), Herklots (1961), Hilty & Brown (1986), Lowen, Bartrina, Clay & Tobias (1996), Meyer de Schauensee & Phelps (1978), Oniki (1996), de la Peña (1994), Perry (1994), Remsen & Traylor (1989), Remsen, Traylor & Parkes (1986), Rovira & Beltzer (1992), Ruschi (1981-1982, 1982a, 1986), Saibene *et al.* (1996), Salaman & Mazariegos (1998a), Short (1971, 1975), Sick (1993, 1997), Snyder (1966), Stotz *et al.* (1996), Thomas, B.T. (1979), Todd (1942), Tostain *et al.* (1992), Zimmer (1950f).

131. Tepui Goldenthrout

Polytmus milleri

French: Colibri des tépuis **German:** Tepuiglänzkehlchen **Spanish:** Colibri de Tepui

Taxonomy. *Waldronia milleri* Chapman, 1929, Mount Duida, 4700 feet [c. 1450 m], Venezuela.

Genus probably constitutes an old Guianan and C Brazilian element with close morphological and behavioural affinities with *Leucochloris* and *Leucippus*. Formerly separated in monotypic genus *Waldronia*. Forms a superspecies with *P. guainumbi*. Monotypic.

Distribution. Table mountains in Venezuela (Duida, Jauna, Auyán Tepui, Parítepui, Roraima and Serra de Pacaraima) and N Brazil (Roraima).

Descriptive notes. 11-12 cm (including bill of 2.5 cm); male 5.6-1 g, female 4.1-4.8 g. Male similar to *P. guainumbi* but no white at eye; long, slightly decurved bill is black; upperparts bronzy-green; below glittering green; central pair of rectrices bronze-green above, iridescent green below, all other tail feathers green, broadly white at base, more narrowly tipped white. Female like male but smaller; mainly dull white below, heavily dotted golden green, densest on breast; more lightly coloured underneath. Immature like adult but with buffy fringes to head feathers.

Habitat. Cloudforest edge, scrub with scattered trees at 1300-2200 m. Forages low down at periphery of vegetation; solitary.

Food and Feeding. Nectar of flowering terrestrial Bromeliaceae, Gesneriaceae, Ericaceae, or Myrtaceae. Insects are caught in the air by hawking, spiders are gleaned from rock cavities and vegetation.

Breeding. May-Jun. Cone-shaped nest, lined with fine plant fibre, decorated with lichen and fragments of leaf, is saddled in fork of shrub, rather exposed, at 0.5-1 m above ground. Clutch size 2; incubation 15-16 days, by female.

Movements. Sedentary, with some altitudinal dispersal after breeding.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species; present in Tepuis EBA. A little-known tepui endemic. Uncommon to locally common along cloudforest ridges of table mountains. Frequently recorded in La Escalera area, in E Bolívar (Venezuela).

Bibliography. Forrester (1993), Gilliard (1941), Grantsau (1988), Mayr & Phelps (1967), Meyer de Schauensee (1982), Meyer de Schauensee & Phelps (1978), Olrog (1968), Renjifo *et al.* (1997), Ruschi (1981-1982, 1982a, 1986), Sick (1993, 1997), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Zimmer (1950f).

132. Green-tailed Goldenthrout

Polytmus theresiae

French: Colibri tout-vert **German:** Grünschwanz-Glanzkehlchen **Spanish:** Colibri de Teresa
Other common names: Green Goldenthrout

Taxonomy. *Ornismya theresiae*, Da Silva Maia, 1843, Pará, Brazil.

Genus probably constitutes an old Guianan and C Brazilian element with close morphological and behavioural affinities with *Leucochloris* and *Leucippus*. Formerly separated in monospecific genus *Smaragditus*. Two subspecies recognized.

Subspecies and Distribution.

P. t. theresiae (Da Silva Maia, 1843) - the Guianas and NC Brazil (Amazonas, Pará, Amapá).

P. t. leucorrhous P.L. Selater & Salvin, 1867 - E Colombia and S Venezuela (Bolívar, Amazonas) to NW Brazil (R Negro) and NE Peru (Loreto).

Descriptive notes. 8.9-9.9 cm (including bill 2.5 cm); 3.5-3.9 g. Male has long bill, slightly decurved, upper mandible black, lower flesh-coloured, tipped black; upperparts and underparts shining green,

small white postocular spot; tail roundish, central rectrices green, others green, basally white. Female similar to male, smaller; throat and breast whitish, thickly spotted with green; outer rectrices with narrow white tips. Immature like adult female but with head feathers fringed buff. Race *leucorrhous* generally very similar but vent and undertail-coverts extensively white with green discs.

Habitat. Forest edge and sandy savanna with scattered stands of bushes and small trees from 100 to 300 m altitude.

Food and Feeding. Nectar of flowering Melastomataceae. Arthropods are gleaned

from leaves or caught in the air by hawking. Male occasionally occupies feeding territories; usually both sexes forage by trap-lining.

Breeding. Mar-Apr and Aug-Oct (the Guianas), Oct-Nov (Venezuela), Nov-Mar (Brazil). Small cup-shaped nest of fine, buff-coloured plant fibre and cobweb is built, rather visibly, in fork of low shrub, often Melastomataceae such as *Rhynchanthera* or *Tibouchina*. Clutch size 2; incubation 14 days, by female; chick black with two rows of buff dorsal down; fledging period 20 days, sometimes up to 28 days.

Movements. Sedentary, but some wandering is known in Surinam, where species may occur at coastal mangrove areas in Jan-Feb.

Status and Conservation. Not globally threatened. CITES II. A common and locally very abundant savanna bird at table mountain borders in La Gran Sabana, S Venezuela, and similar habitats in Surinam and French Guiana.

Bibliography. Best *et al.* (1997), Butler (1979), Chubb (1916), Friedmann (1948), Grantsau (1988), Haverschmidt & Mees (1994), Hilty & Brown (1986), Meyer de Schauensee & Phelps (1978), Parker *et al.* (1982), Ruschi (1953a, 1981-1982, 1982a, 1986), Sick (1993, 1997), Snyder (1966), Stotz *et al.* (1996), Thomas, B.T. (1979), Tostain *et al.* (1992), Zimmer (1950f).

Genus *LEUCIPPUS* Bonaparte, 1850

133. Buffy Hummingbird

Leucippus fallax

French: Colibri trompeur

German: Zimbrustkolibri

Spanish: Colibrí Ante

Taxonomy. *Trochilus fallax* Bourcier, 1843, Caracas, Venezuela.

Proposed races *cervina* (NE Colombia), *occidentalis* (NW Venezuela) and *richmondi* (Margarita I and Tortuga I, off NC Venezuela) are doubtfully distinct; differences apparently represent individual variation. Monotypic.

Distribution. Coastal area of Colombia and Venezuela and adjacent offshore islands.

Descriptive notes. 8.5-9 cm. Male has straight bill, upper mandible black, lower fleshy tipped black; upperparts faded dull green, postocular spot white; underparts pale cinnamon-buff, lower belly white, undertail-coverts white; tail slightly rounded, dull green with dusky grey subterminal bar, tipped white. Much individual variation in overall tone of coloration, from paler to brighter birds, in past forming basis of proposed races. Female similar to male, but tends to be generally duller. Immature resembles adult female.

Habitat. Xeric areas, arid thorny scrub and mangroves, from sea-level up to 550 m. For-

ages at low to medium level in bushes and trees.

Food and Feeding. Feeds on nectar of flowering *Agave*, *Hibiscus*, *Lemairocereus*, *Melocactus* and *Opuntia*. Has been reported to feed on juice of fruits of *Lemairocereus*. Catches insects in the air by hawking.

Breeding. Nests have been found in May and Nov, suggesting breeding period in the rainy season (May-Nov/Dec); one fledgling fed by female in early Dec (Venezuela). Cup-shaped nest is small, made from soft fibres of *Gossypium arboreum* fruits, exterior is decorated with bark, pieces of leaves and lichens; saddled on horizontal branch or in fork of twig, 1.5-2 m above ground. Clutch size 2; no data on incubation and fledging periods available.

Movements. Some seasonal dispersal; during dry season (Dec-Apr) is more abundant in thorn forest and almost absent in the more arid thorn scrubs.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species; present in Caribbean Colombia and Venezuela EBA. Common, and most abundant hummingbird species within its rather specialized habitat. Accepts man-made environments like flowering gardens, and is common in suburbs. Parts of habitat are under threat of destruction resulting from rapidly growing tourism in Venezuela; range is partly protected by several national parks, e.g. Henri Pittier National Park (Venezuela).

Bibliography. Berlepsch (1908), Cory (1915), Deignan (1961), Friedmann & Smith (1955), Harrison (1982), Hilty (1994), Hilty & Brown (1986), McNeil & Rodríguez (1985), Meyer de Schauensee (1982), Meyer de Schauensee & Phelps (1978), Olrog (1968), Phelps & Phelps (1949a, 1958), Robinson & Richmond (1895), Salaman & Mazariegos (1998a), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Todd & Carriger (1922).

134. Tumbes Hummingbird

Leucippus baeri

French: Colibri de Tumbes

German: Baerkolibri

Spanish: Colibrí de Tumbés

Taxonomy. *Leucippus Baeri* Simon, 1901, Tumbes, Peru. Monotypic.

Distribution. Extreme SW Ecuador (Loja) and extreme NW Peru (Tumbes, Piura, Lambayeque).

Descriptive notes. 9-10 cm; 4.3-4.6 g. Male has bill straight or slightly decurved, entirely blackish; upperparts light golden green, feathers bordered dark grey; underparts pale cinnamon to greyish-coloured, becoming whitish towards belly; tail light green, inner rectrices with bronzy tips, outer rectrices with dusky grey subterminal band and whitish terminal patch. Female has more greyish tips in outer rectrices. Immature plumage unknown.

Habitat. Desert scrub, dry forest of the littoral, arid tropical zone, also deciduous forest and scrub; from sea-level to 1300 m.

Food and Feeding. Forages for nectar in xerophytic vegetation, for instance at Cactaceae; diet includes small insects.

Breeding. No information available.

Movements. Presumably sedentary.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species; present in Tumbesian Region EBA. Fairly common inhabitant of the littoral region. However, considering the extremely limited range and unknown population size, species is potentially threatened by habitat alterations. Precise limits of range remain uncertain.

Bibliography. Best & Clarke (1991), Best & Kessler (1995), Best *et al.* (1997), Cook (1996), Cory (1918), Greenway (1978), Meyer de Schauensee (1966, 1982), Olrog (1968), Parker *et al.* (1982), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Williams & Tobias (1994), Zimmer (1950f).

135. Spot-throated Hummingbird

Leucippus taczanowskii

French: Colibri de Taczanowski

German: Taczanowskikolibri

Spanish: Colibrí de Taczanowski

Other common names: Taczanowski's White-throat

Taxonomy. *Thaumasius taczanowskii* P. L. Sclater, 1879, Guajungo, Cajamarca, Peru.

Formerly placed in monospecific genus *Thaumasius*, or with *L. chlorocercus* and sometimes *L. hypostictus* in *Talaphorus*. Proposed race *fractus*, from Huancabamba (N Peru), doubtfully distinct. Monotypic.

Distribution. W slope of C Andes in N & C Peru.

Descriptive notes. 11.5-12.5 cm; male 7-7 g, female 6-9 g. Male has bill slightly decurved, long, almost blackish; bronze crown; upperparts greyish golden-green to bronze-green; uppertail-coverts bronze, fringed greyish; underparts light drab grey, with glittering golden green spots on chin, throat and flanks; undertail-coverts with light brown centres, whitish edges; inner rectrices entirely greyish-green to bronze-green, outer rectrices becoming more greyish with subterminal bronze patch. Female very similar to male. Immature plumage unknown.

Habitat. Inhabits dry forest and desert scrub with Cactaceae, and plantations. Regularly found between 350 and 1000 m, occasionally up to 3000 m.

Food and Feeding. Nectar of various native and introduced plants such as *Agave* and banana (*Musa*). Insects are caught in the air by hawking.

Breeding. No information available.

Movements. No information available.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species; present in Marañón Valley EBA and Peruvian High Andes EBA. Considered to be locally fairly common within the arid tropical zone. Occurs in the Trujillo-Chiclayo area.

Bibliography. Bangs & Noble (1918), Cory (1918), Davies *et al.* (1994, 1997), Koepcke (1961), Meyer de Schauensee (1982), Moynihan (1979), Olrog (1968), Parker *et al.* (1982), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Taczanowski (1884), Zimmer (1950f).

136. Olive-spotted Hummingbird

Leucippus chlorocercus

French: Colibri à queue verte

German: Fleckenkolibri

Spanish: Colibrí Blanquioliva

Taxonomy. *Leucippus chlorocercus* Gould, 1866, upper River Ucayali, eastern Peru.

Formerly placed in genus *Talaphorus*, alone or with *L. taczanowskii*, sometimes also with *L. hypostictus*. Monotypic.

Distribution. Extreme SE Colombia, E Ecuador, NE Peru and extreme NW Brazil.

Descriptive notes. 12 cm; 6.0 g. Male has straight, medium-sized, blackish bill; crown and neck bronze; rest of upperparts greyish-green to bronze-green; underparts whitish; throat with olive green, at certain light angles glittering golden green spots; tail pale greyish-green to olive green; greyish tips to median rectrices, extending to the outer webs in lateral rectrices; dark subterminal bar in outer rectrices. Female similar to male, bill slightly longer. Immature with more greyish-brown on underparts.

Habitat. Evergreen tropical forests and glades of upper Amazon Basin and tributaries; occurs

below 150 m.

Food and Feeding. Forages for nectar at species of diverse plant families, including Leguminosae, Lorantaceae, Vochysiaceae, Bromeliaceae, Rutaceae, Bombacaceae, Malvaceae, Rubiaceae, Myrtaceae, Passifloraceae. Gleans insects from leaf surfaces.

Breeding. Breeding season unknown. Nest cup-shaped, made of soft plant material, fibres, cobweb, externally decorated with lichen; placed on horizontal branch at height of 2-10 m. Clutch size 2; incubation 14-15 days, by female; fledging at 20 days.

Movements. Some local dispersal.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species; present in Upper Amazon-Napo Lowlands EBA. Fairly common to rare resident along riversides. Potentially threatened by deforestation, caused for example by burning. Range limits unclear; current distribution in Ecuador and NW Brazil needs further clarification.

Bibliography. Anon. (1972), Best *et al.* (1997), Butler (1979), Forrester (1993), Grantsau (1988), Hilty & Brown (1986), Meyer de Schauensee (1982), Olrog (1968), Parker *et al.* (1982), Romero (1978), Ruschi (1986), Sclater & Salvin (1866), Sick (1993, 1997), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Taczanowski (1884), Zimmer (1950f).

137. White-bellied Hummingbird

Leucippus chionogaster

French: Ariane à ventre blanc **German:** Weißbauchamazilie **Spanish:** Colibrí Ventrínveo

Taxonomy. *Trochilus chionogaster* Tschudi, 1845, Peru.

Has been included by most modern taxonomists in genus *Amazilia*, but separation from *Leucippus* cannot be maintained, for reasons of morphology, behaviour and biogeography. In past, alternatively placed in genus *Chionogaster*, along with *L. viridicauda*; sympatric with that species in Urubamba Valley (C Peru), but hybridization not yet demonstrated. Formerly listed as *L. pallidus*. Proposed race *longirostris*, described from Salta, Argentina, doubtfully distinct from *hypoleucus*; differences in morphometry (e.g. bill length) and plumage characters of subpopulation concerned appear not to be significant. "*L. nigriristris*" generally considered synonym of present species, though may be better considered unidentifiable. Two subspecies recognized.

Subspecies and Distribution.

L. c. chionogaster (Tschudi, 1844) - N & C Peru.

L. c. hypoleucus (Gould, 1846) - SE Peru, Bolivia and NW Argentina; possibly also EC Brazil (Mato Grosso) and Paraguay.

Descriptive notes. 9-12 cm; male 5-5 g, female 4-5 g. Male has straight, medium-sized bill, upper mandible blackish, lower reddish with dark tip; upperparts, sides of chest and flanks golden to light brilliant green; underparts centrally whitish, sparsely spotted golden green on chin and sides of throat; undertail-coverts whitish, sometimes basally golden green; inner rectrices greyish brilliant green to golden green; outer rectrices with white coloration extending to inner webs. Female has chin and throat lightly cream-coloured, the latter more heavily spotted green. Immature shows cream-coloured parts extending to belly;

generally more greener below. Race *hypoleucus* has generally more cream-coloured tinge to underparts; extension of white parts of outermost rectrices covers only the basal half of inner webs; female with characteristic white terminal patch in outer three rectrices.

Habitat. Inhabits forest edges, second growth, wooded ravines, shrub, *cerrado*, plantations, gardens; prefers fairly dry, bushy areas of with Cactaceae, *Agave*, groves of *Alnus* or *Eucalyptus*. Mainly found in the sub-montane, humid temperate to upper tropical zone between 450 and 2000 m; occasionally up to 2800 m.

Food and Feeding. Feeds on nectar of various plants of different families, such as Leguminosae, Vochysiaceae, Malvaceae, Lorantaceae, Bignoniaceae, Bombacaceae, Passifloraceae, Musaceae. Diet also includes small insects.

Breeding. Jan-Mar. Nest cup-shaped, made of plant wool and moss, covered with lichens; located in shrubs or on lower branches of small trees, 2-5 m above ground. Clutch size 2; incubation 14-15 days, by female; fledging period 19-22 days.

Movements. Sedentary; some local dispersal in Argentina.

Status and Conservation. Not globally threatened. CITES II. Locally common. May suffer from destruction of habitat by burning or grazing, especially in areas of relatively arid, open to semi-open vegetation, as in Gran Chaco of SE Bolivia and N Argentina. Common in Calilegua National Park, Jujuy (Argentina).

Bibliography. Babarskas *et al.* (1995), Bond & Meyer de Schauensee (1943), Canevari *et al.* (1991), Contreras *et al.* (1990), Cory (1918), Esteban (1953), Fjeldså & Krabbe (1990), Flores & Capriles (1998), Forrester (1993), Grantsau (1988), Meyer de Schauensee (1982), Narosky & Yzurieta (1993), Parker *et al.* (1982), de la Peña (1994), Pinto (1938), Remsen & Traylor (1989), Ruschi (1986), Schmitt *et al.* (1997), Short (1975), Sick (1993, 1997), Stotz *et al.* (1996), Taczanowski (1884), Wetmore (1926), Zimmer (1930, 1950f).

138. Green-and-white Hummingbird

Leucippus viridicauda

French: Ariane du Pérou **German:** Grünweißamazilie **Spanish:** Colibrí Blanquiverde

Taxonomy. *Leucippus viridicauda* Berlepsch, 1883, Huyro, 4800 feet [c. 1470 m], Peru. Often placed in genus *Amazilia*, but separation from *Leucippus* cannot be maintained, for reasons of morphology, behaviour and biogeography. In past, alternatively placed in genus *Chionogaster*, along with *L. chionogaster*; sympatric with that species in Urubamba Valley (C Peru), but hybridization not yet demonstrated. Monotypic.

Distribution. E slope of Andes in C Peru.

Descriptive notes. 10-11 cm; male 6-0 g, female 5-5 g. Male has straight, medium-sized bill, upper mandible blackish, lower reddish with dark tip; upperparts and flanks brilliant to bronze-green; centre of underparts whitish, spotted greenish on sides of chin and throat; undertail-coverts whitish, sometimes basally golden green; rectrices greyish-green to golden green without white basal portions. Differs from rather similar *L. chionogaster* by duller, more olive tone to green of upperparts. Female has chin and throat light cream-coloured, the latter more heavily spotted green. Immature has cream-coloured parts extending to belly.

Habitat. Forest edges, clearings and second growth in the humid subtropical zone between 1000 and 2500 m.

Food and Feeding. Nectar of various plant species, also small arthropods.

Breeding. Poorly known. Breeding has been observed in Jan, possibly representing the seasonal peak; additionally, nest-building was recorded in Jul. Nest cup-like, with moss, plant wool, lichen and cobweb; often placed on horizontal branches of smaller trees. Clutch size 2; incubation by female; no data exist on incubation and fledging periods.

Movements. Probably some local dispersal.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species; present in Peruvian East Andean Foothills EBA. Fairly common breeder in Pasco, and around Machu Picchu in Cuzco. In view of its limited distribution and the scant information available about its biology and ecological requirements, further field studies are needed to clarify the type of conservation measures required for this species.

Bibliography. Fjeldså & Krabbe (1990), Meyer de Schauensee (1982), Olrog (1968), Parker *et al.* (1982), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Taczanowski (1884), Terborgh *et al.* (1984), Zimmer (1950f).

139. Many-spotted Hummingbird

Leucippus hypostictus

French: Colibrí grivelé **German:** Tropfenkolibri **Spanish:** Colibrí Moteado

Taxonomy. *Aphantochroa hyposticta* Gould, 1862, Ecuador.

Sometimes placed in monospecific genus *Tuphrospilus*; alternatively, in past, sometimes placed with *L. taczanowskii* and *L. chloroceryx* in *Talaphorus*. Proposed race *peruvianus* fits well into overall pattern of variation within the species, so subspecific status cannot be maintained. Monotypic.

Distribution. E Andes in E Ecuador, E Peru and C & SE Bolivia to SW Brazil (W Mato Grosso) and NW Argentina.

Descriptive notes. 10.5-11.4 cm; 6-7-7.2 g. Male has slightly curved, medium-sized black bill; upperparts grass green to coppery bronze, white postocular spot; underparts white, heavily spotted green except on central belly; tail blue-green, tipped dusky grey. Female similar to male but lighter underneath. Immature like adult, but has buffy fringes to head feathers.

Habitat. Forest and forest edges along small ravines of Andean foothills at 400-1000 m. Most numerous around 600 m. Forages from low to mid-strata, usually inside vegetation.

Food and Feeding. Nectar of flowering shrubs, terrestrial bromeliads, vines, trees, including *Palicourea*, *Centropogon*, *Pitcairnia*, *Passiflora* and *Inga*. Insects are taken in the air by hawking, often in clearings or above small streams.

Breeding. Probably Jan-May; one active nest from Apr. Bulky cup-shaped nest of fine rootlets and moss is built low (c. 0-5 m) on tree trunk. Clutch size 2; incubation 14-15 days, by female; fledging at 20-22 days.

Movements. Sedentary.

Status and Conservation. Not globally threatened. CITES II. Common throughout range. A little-studied species which seems to tolerate secondary growth. Occurs between Tena and Coca (NE Ecuador), and between Cuzco and Manu (Peru).

Bibliography. Albuja & De Vries (1977), Best *et al.* (1997), Butler (1979), Fjeldså & Krabbe (1990), Forrester (1993), Grantsau (1988), Meyer de Schauensee (1982), Olrog (1968), Parker *et al.* (1982), Remsen & Traylor (1989), Ruschi (1982a, 1986), Stotz *et al.* (1996), Todd (1942), Zimmer (1950f).

Genus *AMAZILIA* Lesson, 1843

140. Rufous-tailed Hummingbird

Amazilia tzacatl

French: Ariane à ventre gris **German:** Braunschwanzamazilie **Spanish:** Amazilia Tzacatl
Other common names: Rieffer's Hummingbird; Escudo Hummingbird (*handleyi*)

Taxonomy. *Trochilus Tzacatl* De la Llave, 1833, Mexico.

Forms a superspecies with *A. castaneiventris*, but not, as sometimes suggested, with *A. rutila* and *A. yucatanensis*, given considerable distributional overlap with former in Central America. Race *handleyi* has been treated as a distinct species, due mainly to its much larger size, but this is untenable due to zone of morphometric intergradation with nominate in Bocas del Toro Archipelago. Validity of race *fuscaudata* has been questioned, but supported by morphometric characters. "*A. bangsi*" is a hybrid of present species and *A. rutila*. Four subspecies recognized.

Subspecies and Distribution.

A. t. tzacatl (De la Llave, 1833) - CE (possibly NE) Mexico to C Panama.

A. t. handleyi Wetmore, 1963 - I Escudo de Veraguas (off NW Panama).

A. t. fuscaudata (Fraser, 1840) - N & W Colombia and W Venezuela.

A. t. jucunda (Heine, 1863) - SW Colombia and W Ecuador.

Descriptive notes. 8-11 cm; male 5.5 g, female 5.2 g, race *handleyi* (unsexed) 7.0 g. Male has bill straight, medium-sized, fleshy red with dark tip, or upper mandible blackish; upperparts, flanks and belly golden green to bronze-green; throat glittering golden green, sometimes with a turquoise gleam in certain lights; belly ashy grey to greyish-brown; tail rufous, rectrices with bronze-green to copperish margins. Female similar to male, but has greyish subterminal bars on throat feathers, and white belly. Immature darker greyish towards belly. Race *handleyi* considerably larger and heavier, slightly darker bronze-green above; *fuscaudata* is smaller in all

measurements; *jucunda* has longer bill in relation to size, and narrowed margins in outer rectrices.

Habitat. Edges of humid evergreen forest, clearings, plantations of bananas or coffee, human habitations; usually not inside dense forest. Often in second growth and semi-open, thicket-rich areas; in South America, partially in gallery forest and mangrove. Ranges in Costa Rica and Panama through the subtropical belt occasionally into lower montane zones, from sea-level up to 1200 m. On islands of Panama and in Colombia, inhabits primary forest as well as bushy coastal habitats, even beaches; in northern Andes, found up to 2500 m, occasionally higher. In SW Colombia, race *jucunda* ranges from lowlands into the subtropical zone with wet, open forest elements, up to 2500 m.

Food and Feeding. Nectar and arthropods. Found in all strata from near the ground to the more open sides of tree crowns; frequently gathers in some numbers with conspecifics or congeners such as *A. amazilia* and *A. rutila*. Generalist forager; feeding has been observed at a wide variety of plants, including *Antigonon*, *Callistemon*, *Clitoria*, *Costus*, *Iseria*, *Hamelia*, *Heliconia*, *Stachytarpheta*, *Tabebuia*, *Lantana*, and diverse cultivated tree species, especially banana and coffee; sometimes along roadsides. Occasionally perches at the end of the petals of larger flowers, or on adjacent blossoms. In Colombia, use of holes in corollae of *Thunbergia* flowers previously pierced by Bananquits (*Coereba flaveola*) observed. Gleans insects and small spiders from leaves and branches. Mainly territorial, also when associated in groups; intruders, even larger trochilids, Hesperidae butterflies, and euglossine bees are sometimes attacked in "diving" flight.

Breeding. Almost all year round. In northern parts of Central America, nesting records Dec-Sept; in Mexico, mainly Mar-Aug, correlated with moulting period Sept-Dec. In Costa Rica, breeding period peaks Jan-May, according to dry season; birds on Pacific slope breed May-Nov, on Caribbean slope Oct-Jun; in Panama and South America, Jan-Apr. Favourite nest-sites are horizontal branches in smaller trees or shrubs, mostly 2-5 m (<1.7 m) above ground; sometimes nest placed in fork. Nest material varies, and includes plant down, yellowish-brown to greyish-brown fibres, cobweb, pieces of dead leaves, and lichens in the form of a compact cup. Clutch size 2; incubation 15-16 days, by female; chick blackish, with buff down; fledging at 18-22 days. May form very loose "colonies", where stealing of nesting material has been observed. After loss of a nest, construction of a new one may start within one week.

Movements. In humid regions generally more sedentary than in arid areas; more or less all year round inhabitant of tropical wet forests. Northernmost population probably winters along Pacific and Caribbean coast of Mexico, i.e. Guerrero and Yucatán. Vagrants may occur farther north of the range limit and have been recorded from S Texas in summer and autumn. Migrational trends not known in other parts of Central America; race *handleyi* probably sedentary. Seasonal movements are known from Colombia and Ecuador since altitudinal distribution varies with flowering periods of food plants, though to what extent remains to be studied.

Status and Conservation. Not globally threatened. CITES II. Common to very common in most of range, e.g. Canal Zone of Panama. Less abundant in regions with tropical dry forest, dense rainforest and lower montane forest. Readily accepts man-made habitats, thus one of the most frequent trochilids in areas of habitation and cultivation. Race *handleyi*, with tiny range, may require monitoring.

Bibliography. Andrie (1967), Bangs (1930), Bent (1940), Berg (1994), Binford (1989), Blake & Loiselle (1991), Bloch *et al.* (1991), Borrero (1965, 1972, 1975), Boyden (1978), Brosset (1964), Brown & Bowers (1985), Butler (1932a, 1932b), Carriker (1910), Chapman (1917), Darlington (1931), Deignan (1936), Edwards & Tashian (1959), Eisenmann (1957), Fairchild *et al.* (1977), Feinsinger (1976, 1977, 1980), Fjeldså & Krabbe (1990), Friedmann *et al.* (1950), Fritsch & Schuchmann (1988), Gray (1958), Hartert (1898), Hartman & Lessler (1963), Heath (1932), Heine (1863), Hilty (1985, 1997), Hilty & Brown (1986), Howell, S.N.G. & Webb (1995a), Howell, T.R. 141. Chestnut-bellied Hummingbird

Amazilia castaneiventris

French: Ariane à ventre roux **German:** Braunbauchamazilie **Spanish:** Amazilia Ventricastaña

Taxonomy. *Amazilia castaneiventris* Gould, 1856, Santa Fé de Bogotá, Colombia.

Forms a superspecies with *A. tzacatl*, but not, as sometimes suggested, with *A. rutila* and *A. yucatanensis*. Monotypic.

Distribution. W slope of E Andes of NC Colombia.

Descriptive notes. 9 cm. Male has straight, medium-sized, blackish bill with fleshy red base to lower mandible; upperparts bronze-green; throat and upper breast glittering golden green; lower belly, undertail-coverts and rectrices chestnut-coloured, latter with greenish borders. Female similar to male, but with white subterminal bars on upper throat feathers, and slightly paler belly. Immature has rufous feather borders on neck and rump.

Habitat. Inhabits bushy canyons and edges of lower montane humid forest. Mainly found between 500 and 1500 m, rarely up to 2000 m; one lowland record at 120 m.

Food and Feeding. Forages for nectar at various plant species, including *Salvia* and *Trichanthera*; diet also includes small arthropods.

Breeding. Breeding condition of specimens suggests season from Aug to Dec. Clutch size 2; incubation by female; no data on incubation or fledging periods.

Movements. May occur at lower altitude after breeding season.

Status and Conservation. ENDANGERED. CITES II. Restricted-range species; present in Nechi Lowlands EBA and Colombian East Andes EBA. By far the rarest representative of the genus; current status and population size unknown, and species has not been observed during the past two decades; formerly locally common in Santander. Due to insufficient information on distribution and biology, especially habitat requirements, suitable protection measures have yet to be proposed or enforced; has presumably suffered from the extensive deforestation within its range.

Bibliography. Berlioz (1962), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Feinsinger, Tiebout, Young & Murray (1991), Hilty (1985), Hilty & Brown (1983, 1986), Linhart *et al.* (1987), Meyer de Schauensee (1982), Olrog (1968), Paynter & Taylor (1981), Renjifo *et al.* (1997), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Warren (1966), Wege & Long (1995).

142. Amazilia Hummingbird

Amazilia amazilia

French: Ariane de Lesson **German:** Rostbauchamazilie **Spanish:** Amazilia Costeña

Taxonomy. *Orthorhynchus* [sic] *Amazilia* Lesson, 1826, Callao de Lima, Peru.

Forms a superspecies with *A. alticola*, with which formerly considered conspecific; differs in coloration, song repertoire and habitat requirements, with no hybridization yet reported where the two are probably parapatric in S Ecuador. Race *leucophaea* frequently misspelt as *leucophaea*. Four subspecies recognized.

Subspecies and Distribution.

A. a. dumerilii (Lesson, 1832) - W of Andes from W Ecuador to N Peru; E slope in SE Ecuador (upper Zamora Valley).

A. a. leucophaea Reichenbach, 1854 - NW Peru.

A. a. amazilia (Lesson, 1826) - W Peru.

A. a. caeruleigularis Carriker, 1933 - SW Peru (Nazca Valley).

Descriptive notes. 9-11 cm; male 5.0 g, female 4.5 g. Male has straight, medium-sized, flesh red bill with dark tip; golden green upperparts; throat glittering golden to turquoise green, normally without white patch; lower breast and belly rufous; uppertail-coverts and tail rufous, rectrices laterally bronze-green. Female strongly resembles male, but sometimes has more conspicuous white subterminal bars on chin and throat feathers; lighter rufous on belly. Immature has brownish borders on feathers of upperparts. Races *dumerilii* and *leucophaea* smaller, with white chin feathers, throat patch and centre of belly, and *leucophaea*

is bronze-green above; birds of race *dumerilii* from W Ecuador show greyish-green rectrices; *caeruleigularis* distinguished by glittering violet-blue throat patch.

Habitat. In contrast to other members of genus, prefers semi-arid to arid open, partially coastal, habitats with scrub, thorn forest, xerophytic steppe and desert areas. Rarer in forested areas, mainly in the tropical zone along the Pacific coast. The races *dumerilii* and *leucophaea* reach sub-montane, sub-tropical zones. Also common in cultivation and habitations, even parks and gardens within cities such as Lima. Ranges mostly from sea-level to 1000 m (races *amazilia*, *dumerilii*). Race *leucophaea* shows greatest altitudinal tolerance of all subspecies, reaching montane elevations of up to 2700 m in Cajamarca;

On following pages: 143. Loja Hummingbird (*Amazilia alticola*); 144. Buff-bellied Hummingbird (*Amazilia yucatanensis*); 145. Cinnamon Hummingbird (*Amazilia rutila*); 146. White-chested Emerald (*Agyrtia brevirostris*); 150. Andean Emerald (*Agyrtia franciae*); 151. White-bellied Emerald (*Agyrtia candida*); 152. Azure-crowned Hummingbird (*Agyrtia cyanocephala*); 153. Violet-crowned Hummingbird (*Agyrtia violiceps*); 154. Green-fronted Hummingbird (*Agyrtia viridifrons*).

however, mainly restricted to sub-montane elevations at 500–1500 m. Race *caeruleigularis* apparently restricted to desert-like, sub-montane habitats between 600 and 700 m.

Food and Feeding. Feeds on nectar of flowering *Erythrina*, *Psittacanthus*. Catches small insects and spiders. Male establishes territory; interspecific competition with other trochilids like *Leucippus baeri* and *Myrmia micrura* has been observed.

Breeding. Breeds all year round. Nest cup-like, 3 cm high, made of plant wool, brown fibres, white seed pappi, fixed with cobweb. Nest-sites include tops of overhanging and flat branches, sometimes ends of horizontal branches, c. 1–2.5 m above ground. In Ecuador, nests were found in cypress and porotillo bushes; during rainy season often in scrub with dense foliage. Clutch size 2; incubation 16–18 days, by female; chick blackish, with buff down; fledging period 17–25 days.

Movements. Some altitudinal dispersal after main breeding season.

Status and Conservation. Not globally threatened. CITES II. Common to uncommon along the Pacific coast and some Andean valleys of the Pacific slope; the commonest trochilid regionally. Race *dumerilii*, mainly of W Andes, known on E Andean slope only from upper Zamora Valley (SE Ecuador), where probably isolated from western populations. Southernmost race *caeruleigularis* is extremely local and occurs only in the Nazca Valley; probably still common there. Although no special measures for its protection have been taken, this race may profit from the geohistorical importance of the area, which contains unique Inca cultural monuments.

Bibliography. Baron (1897), Becker & López (1997), Berg (1994), Berlioz (1932c), Best & Clarke (1991), Best *et al.* (1997), Butler (1979), Carriker (1933), Chapman (1926), Elgar (1986, 1987), Fjeldså & Krabbe (1990), Koepecke (1970), Landman (1991), Lanyon (1975), Marchant (1959, 1960), Mischler (1986), Parker, Parker & Plenge (1982), Parker, Schulenberg *et al.* (1995), Pople *et al.* (1997), Schulenberg & Parker (1981), Stotz *et al.* (1996), Williams & Tobias (1994), Zimmer (1930, 1950f).

143. Loja Hummingbird

Amazilia alticola

French: Ariane alticole

German: Lojaamazilie

Spanish: Amazilia de Loja

Taxonomy. *Amazilia alticola* Gould, 1860, Puna district, Peru; error = Loja, Ecuador.

Forms a superspecies with *A. amazilia*, of which formerly considered a race; differs in coloration, song repertoire and habitat requirements, and probably parapatric with *A. amazilia dumerilii* in Casanga Valley (C Loja), where no interbreeding yet observed. Monotypic.

Distribution. Andes of S Ecuador; doubtfully N Peru.

Descriptive notes. 10–11 cm; male 6–5 g, female 5–5 g. Male has straight, medium-sized bill, fleshy red with dark tip; upperparts golden green; underparts mainly whitish, with green spots on chin and upper throat; cinnamon-rufous more reduced on breast than in *A. amazilia*; nearly all rectrices rufous, except for the innermost which show greenish traces; colour of undertail-coverts varies from pure white to rufous. Female has more whitish on chin; mostly lacks rufous sides. Immature has brownish borders on neck, lower back and rump feathers.

Habitat. Inhabits edges of cloudforest, clearings, semi-open to open scrub, and bushy savanna of the sub-montane zone. Recorded between 1000 and 2200 m but commonest above 1500 m.

Food and Feeding. Poorly known. Forages for nectar at flower corollas of medium length, where occasionally territorial. Feeds on small arthropods in the air and gleans them from leaves.

Breeding. Nov–Mar. Nest is an open cup, saddled on horizontal branch to which it is fixed with cobweb; made of plant down and decorated on the outside with lichens. Clutch size 2; incubation by female; chick blackish, with some buff dorsal down; no data exist on duration of incubation or fledging.

Movements. Unknown in detail; probably sedentary. May occur at lower altitudes after reproduction. **Status and Conservation.** Not globally threatened. CITES II. Restricted-range species; present in Southern Central Andes EBA. Common to locally common in suitable habitats; however, probably threatened by habitat destruction, in particular deforestation. As a result of this, the preferred cloudforest habitats are becoming more and more isolated from each other, which explains the species' increasingly rather patchy distribution.

Bibliography. Best *et al.* (1997), Bloch *et al.* (1991), Chapman (1926), Hüning (1999), Williams & Tobias (1994), Zimmer (1950f).

144. Buff-bellied Hummingbird

Amazilia yucatanensis

French: Ariane du Yucatan

German: Fahlbauchamazilie

Spanish: Amazilia Yucateca

Other common names: Fawn-breasted/Yucatan Hummingbird

Taxonomy. *Trochilus yucatanensis* Cabot, 1845, Yucatán, Mexico.

Forms a superspecies with *A. rutila*, but not, as sometimes suggested, with *A. tzacatl* and *A. alticola*. Race *cerviniventris* formerly treated as a distinct species, including race *chalconota*. Three subspecies recognized.

Subspecies and Distribution.

A. y. chalconota Oberholser, 1898 - extreme S USA (Texas) to NE Mexico (S to San Luis Potosí).

A. y. cerviniventris (Gould, 1856) - E Mexico (Veracruz, Puebla, Chiapas).

A. y. yucatanensis (Cabot, 1845) - SE Mexico (Tabasco, Campeche, Yucatán), N Belize and NW Guatemala; erroneously reported from Honduras.

Descriptive notes. 10–11 cm; male 4–5 g, female 4–0 g. Male has straight, medium-sized bill, fleshy red with dark tip; upperparts golden to bronze-green; throat glittering golden green; belly and undertail-coverts chestnut; tail slightly forked; central rectrices and upperpart-coverts greenish, or chestnut as outer rectrices, with bronze margins, narrowed towards tips. Female has dark upper mandible, whitish subterminal bars on throat feathers, and paler belly and undertail-coverts. Immature has duller crown, brownish borders on neck and rump feathers and less forked tail. Coloration of belly reflects intergradation between races, darkest in nominate race, becoming successively paler in *cerviniventris* and *chalconota*; *chalconota* has silky gloss on throat; *cerviniventris* has shorter wings and tail.

Habitat. Race *chalconota* prefers rather open habitats, like pine-oak forests, semi-arid coastal shrub, second growth, sometimes along ravines or smaller streams; in Texas, also inhabits patches

Breeding. On Yucatán Peninsula, Jan–Apr; in NE part of range, regularly Feb–Jul, with peak Mar–Jun; in Texas, mid Apr–mid Aug. Nest cup-shaped, small or relatively large and heavy, saddled on small branch or fork of twig, 1–3 m above ground; consists of vegetation fibres, pieces of herb stem, plant down, often of *Gossypium*; covered with lichens, dried blossoms, plant fibres, or pieces of bark, fixed with spiders' webs. Nest-sites are usually located in smaller trees and bushes like willow, hackberry, *Cordia*, or *Pithecellobium*; sometimes built beside a forest path or road. Clutch size 2; incubation by female; no data exist on incubation and fledging periods; chick buff with black dorsal down.

Movements. Partially migratory. Generally in lower numbers in breeding range Oct–Apr. Individuals of race *chalconota* migrate irregularly in autumn or winter NE along Gulf of Mexico coast, reaching Louisiana, Mississippi and Florida; rarely even farther north; southward-directed migration recorded in Mexico as far as Veracruz. Race *cerviniventris* has been recorded in late summer from SW Campeche (Yucatán Peninsula). Nominate birds are presumed to winter further south within Mexico in Tabasco and Chiapas. Not reported in winter on the Pacific slope.

Status and Conservation. Not globally threatened. CITES II. Usually, an abundant to common breeder, at least locally. Race *chalconota* has become a rare breeder in Rio Grande delta, due to rapid destruction of breeding habitat by spread of agriculture and pastures, use of biocides, and road construction. Race *yucatanensis* becomes uncommon to rare along its southern limits in Petén, Guatemala. Status for Honduras, either as migrant or breeding species, is questionable; in view of specimens supposedly of present species that were subsequently identified as hybrids of *A. tzacatl* x *A. rutila*, possible sightings require conclusive confirmation, particularly if no clear indication of regular occurrence is given.

Bibliography. Andrie (1967), Baicich & Harrison (1997), Bendire (1896), Bent (1940), Binford (1989), Bjelland & Ray (1977), Brewer (1878), Chávez-Ramírez & Moreno (1999), Davis (1952), DeGraaf & Rappole (1995), Ford (1938), Friedmann *et al.* (1950), Gehlbach *et al.* (1976), Griscom & Crosby (1926), Hamilton (1978), Howell & Webb (1995a), Johnsgard (1997), Kale (1985), Kaufman (1996), Land (1970), Lowery (1974), Lowery & Dalquest (1951), Luckner (1992), Lynch (1992), Martins *et al.* (1954), Mayr & Short (1970), Merrill (1877), Monroe (1968), Muth (1988), Newfield (1984), Oberholser (1974), Ogden (1990), Paynter (1955), Pickens (1935b), Purrington (1981, 1988), Ridgway (1911), Russell (1964), Sargent & Sargent (1996b), Stevenson (1953), Stotz *et al.* (1996), Sutton & Burleigh (1940), Sutton & Pettingill (1942), Todd (1942), Waide & Hailman (1977), Warner & Mengel (1951), Wauer (1998), Zimmerman (1957a).

145. Cinnamon Hummingbird

Amazilia rutila

French: Ariane cannelle

German: Zimtbauchamazilie

Spanish: Amazilia Canela

Taxonomy. *Ornismya rutila* DeLatre, 1843, Acapulco, Guerrero, Mexico.

Forms a superspecies with *A. yucatanensis*, but not, as sometimes suggested, with *A. tzacatl* and *A. alticola*, given extensive sympatry with former. Formerly listed as *A. cinnamomea*, but this name was unavailable. Race *graysoni* has sometimes been considered a separate species. Validity of race *diluta* has been doubted because of intergradation towards nominate birds. Name *saturata* is synonym of *corallirostris*. "*A. bangsi*", known from a single Costa Rican specimen, is hybrid of present species and *A. tzacatl*. Populations from Yucatán, Honduras, Nicaragua and Costa Rica, formerly attributed to nominate, are more appropriately placed in *corallirostris* on basis of morphology and biogeography. Four subspecies recognized.

Subspecies and Distribution.

A. r. diluta van Rossem, 1938 - NW Mexico (Sinaloa, Nayarit).

A. r. graysoni Lawrence, 1867 - Is Tres Marias (off W Mexico).

A. r. rutila (Lesson, 1842) - W & SW Mexico (Jalisco to Oaxaca).

A. r. corallirostris (Bourcier & Mulsant, 1846) - S & SE Mexico (from Chiapas and Yucatán) to Costa Rica.

Descriptive notes. 10 cm; male 5–0 g, female 4–5 g. Male has straight, medium-sized bill, fleshy red with dark tip; upperparts golden to bronze or copper-green above; underparts entirely rufous, chin feathers fringed greyish; tail and parts of upperpart-coverts rufous, tips of rectrices bronze-green to purplish. Female has blackish upper mandible, darker chin, and less rufous below. Immature has feathers of upperparts bordered with rufous. Race *diluta* has paler underparts; *graysoni* is considerably larger in all morphometric characters, bill slightly decurved; *corallirostris* has darker underparts, with chin more conspicuously spotted

white, bill in some individuals more coral red.

Habitat. Deciduous and semi-deciduous forests, thorn forests, forest edges, bushy savannas, second growth and around human habitation; mainly in the arid tropical zone. May occur in dense forest but avoids closed gallery forest. On islands such as offshore cays of Belize, found in low coastal scrub vegetation and coconut groves. Ranges from sea-level to 1700 m.

Food and Feeding. Nectar and insects. Often gathers around flowering trees or bushes, sometimes with congeners like *A. tzacatl*. Feeds on *Genipa*, *Luehea*, *Tabebuia* and other trees, shrubs like *Helicteres*, various herbs such as *Lamorouxia*, and vines such as *Combretum*. Perches relatively low down, but shows less feeding height preferences than other associated trochilid species; thus found both in lower and taller trees, usually feeding 6–15 m from ground; otherwise, less than 5 m in lower vegetation. Male defends territory that is normally established on the exterior of a tree crown, and defended against other hummingbirds like *Saucerottia saucerrottei* or *Campylopterus curvieri*, large bees, but rarely against passerines. Insects are caught in the air by hawking.

Breeding. Almost all year round. In W Mexico, nesting or birds in breeding condition were observed May-Feb; in E Mexico (Yucatán), birds in breeding condition were registered Mar-Apr; in El Salvador, Jul-Oct; in Costa Rica, nesting lasts from Dec to Jun, varying with the start of the dry season. Race *graysoni* seems to have prolonged nesting season, with breeding records from nearly all months except Sept and Dec, due to less restricted flower abundance than in mainland habitats. Nest cup-shaped, of plant down, treefern scales, and cobweb; 1-5 m above ground in shrubs or understorey at forest edges. Clutch size 2; incubation by female. No further information.

Movements. Sedentary in Is Tres Marias, partially migratory on mainland, especially N populations. Wintering birds in W Mexico were recorded from Sinaloa and Durango, in E Mexico from N part of Yucatán Peninsula.

Status and Conservation. Not globally threatened. CITES II. Common to very common in most parts of range, but mainly restricted to lower tropical zones with arid vegetation types. In Costa Rica, occurs in several protected areas, e.g. Santa Rosa, Palo Verde and Barra Honda National Parks. Race *graysoni* is confined to Is Tres Marias, where it is a common resident.

Genus AGYRTRIA Reichenbach, 1854

146. Plain-bellied Emerald

Agyrtia leucogaster

French: Ariane vert-doré **German:** Hellbauchamazilie **Spanish:** Amazilia Ventrianca

Taxonomy. *Trochilus leucogaster* J. F. Gmelin, 1788, Cayenne.

Genus usually merged into *Amazilia*. Race *bahiae* initially described based erroneously on characters of nominate birds; its validity has thus been questioned by later taxonomists. Two subspecies recognized.

Subspecies and Distribution.

A. l. leucogaster (J. F. Gmelin, 1788) - E Venezuela, the Guianas and NE Brazil.

A. l. bahiae Hartert, 1899 - E Brazil from Pernambuco to Bahia.

Descriptive notes. 9-10 cm; male 4-5 g, female 4-3 g. Male has bill straight to slightly decurved, blackish except for fleshy red base of lower mandible; crown and sides of neck glittering golden green, rarely with turquoise reflections; rest of upperparts, flanks and sides of throat golden to bronze-green; centre of throat, underparts and undertail-coverts white; inner rectrices bronze-green to bronze, outer rectrices bluish-black; tail slightly forked. Female very similar to male, but has more greenish spots on sides of throat and greyish-green tail tips. Immature has brownish feather margins on back. Race *bahiae* has longer bill and

wings; generally less bronze in coloration.

Habitat. Mangroves, especially *Avicennia*, forest edges, second growth, *cerrado*, *caatinga*, plantations, parks and gardens. Occurs mainly close to sea-level; in Venezuela occasionally up to 250 m.

Food and Feeding. Forages for nectar at herbs and low down at trees and shrubs; preferred plant families are Leguminosae, Vochysiaceae, Musaceae, Acanthaceae, Heliconiaceae, Bignoniaceae, Malvaceae, Bromeliaceae, Anacardiaceae, Verbenaceae and Passifloraceae. Catches small insects in flight by hawking.

Breeding. Recorded Jul-Aug in the Guianas and NE Brazil. Nest cup-shaped, made of plant wool, and sometimes Bromeliaceae, and leaves and other parts of Bombaceae; outer walls decorated with lichen; placed on horizontal branch or in fork of smaller tree or bush, usually less than 5 m above ground, in mangroves sometimes close to water surface. Clutch size 2; incubation 14 days, by female; fledging at 20-25 days.

Movements. Some local dispersal.

Status and Conservation. Not globally threatened. CITES II. A rather common resident of the coastal Guianas and Brazil, especially in mangrove forests. Status in the Brazilian parts of the range needs further clarification since the range boundaries remain unclear, in particular the limits of distribution of the two races. Records of the species away from the Atlantic coast are rare, for instance at Cerro El Trueno, Bolívar (S Venezuela).

Bibliography. Avelledo (1955), Bangs & Penard (1918), Berlepsch (1908), Chubb (1916), Forrester (1993), Grantsau (1988), Hartert (1899a), Haverschmidt (1955a), Haverschmidt & Mees (1994), Jouanin (1948), Meyer de Schauensee & Phelps (1978), Ruschi (1949a, 1981-1982, 1986), Sánchez (1995), Sargeant (1996), Sick (1993, 1997), Sneathlidge (1928a, 1928b), Snyder (1966), Stotz *et al.* (1996), Tobias *et al.* (1993), Tostain (1980), Tostain *et al.* (1992).

147. Versicolored Emerald

Agyrtia versicolor

French: Ariane versicolore **German:** Glanzamazilie **Spanish:** Amazilia Versicolor
Other common names: Cuyuni Emerald (*hollandi*)

Taxonomy. *Trochilus versicolor* Vieillot, 1818, Brazil.

Genus usually merged into *Amazilia*. Often considered to include *A. rondoniae* as a race, but probably better considered a distinct species, on basis of reported sympatry without interbreeding. Taxonomic confusion has been caused by occurrence of polymorphism within southern parts of range: birds from SE Brazil sometimes divided into two distinct races or even species, a green-throated inland one and a white-throated coastal one, but differences attributable to clinal variation within nominate race, and intermediates exist; coastal birds were listed as *brevirostris*, but this name now

considered to refer to the species formerly known as *A. chionopectus*. Distinctive race *hollandi* sometimes considered a separate species, and *millerii* and *nitidifrons* have also been suggested as constituting two further species. Validity of race *kubicheki* has often been questioned, but it appears justified on basis of morphology and biogeography. Race *viridiceps* of *A. franciae* sometimes placed in present species. Five subspecies recognized.

Subspecies and Distribution.

A. v. millerii (Bourcier, 1847) - tropical Colombia E of Andes, C Venezuela and Amazonian E Peru and N Brazil.

A. v. hollandi Todd, 1913 - SE Venezuela; possibly also W Guyana, where status unclear.

A. v. nitidifrons (Gould, 1860) - NE Brazil.

A. v. versicolor (Vieillot, 1818) - SE Brazil.

A. v. kubicheki (Ruschi, 1959) - NE Bolivia, E Paraguay, extreme NE Argentina and SW Brazil.

Precise limits of distribution very poorly known in Amazonia and NE Brazil.

Descriptive notes. 8-10 cm; male 4-0 g, female 3-5 g. Male has bill straight, medium-sized, upper mandible blackish, lower reddish except for dark tip; crown and cheeks dull bronze-green; upperparts shining golden green to bronze-green; chin and throat variable, pure white in coastal subpopulation, more spotted glittering green to entirely green in western subpopulation; centre of underparts white; sides of chest, flanks and undertail-coverts bronze-green, the latter fringed white; tail bronze-green, dark subterminal band on outer rectrices. Female has grey feather tips on outer rectrices. Immature has rufous borders to

crown, lower back and rump feathers; belly brownish. Race *millerii* has shorter bill, crown glittering turquoise, centre of throat entirely white; *hollandi* has bluish crown and cheeks and white throat; *nitidifrons* has turquoise to golden green glittering crown, cheeks and throat spots; *kubicheki* has significantly shorter bill, throat entirely glittering emerald green with turquoise reflections; females of races *kubicheki* and *nitidifrons* show conspicuous white subterminal bars on chin feathers.

Habitat. In northern parts of range, chiefly found at edges of cloud and rainforest and in gallery forest; ranges altitudinally from 50 m in the Amazon basin to 1250 m in the lower sub-montane zone of the eastern slope of E Andes; rarely above 1000 m in the Pantepui region of NE South America, with upper limit at 1700 m. In E and S Brazil, prefers more open habitats with scrub, *caatinga*, or *campo cerrado*; also found in suburban areas such as parks and gardens; mostly below 900 m.

Food and Feeding. Nectar and arthropods; feeds and perches at all levels. Has been observed to visit a great variety of plant families; prefers flowers with short or no corolla tubes, in particular Loganiaceae (*Buddleja*), Asteraceae (*Piptocarpha*), Bromeliaceae (*Tillandsia*, *Vriesea*), Amaryllidaceae (*Alstroemeria*), Zingiberaceae (*Inga*); also many species of Ranunculaceae, Passifloraceae, Bombaceae, Vochysiaceae, Verbenaceae, Labiataceae and Cactaceae. In orchards or suburban areas, common at flowering bushes or trees of *Heliconia*, *Eucalyptus* or *Citrus*. Small arthropods are taken from leaves or caught in the air by hawking.

Breeding. Almost all year round; in E Brazil, Oct-Mar. Nest cup-shaped, built of plant down and seeds of, among others, *Asclepias*, *Chorisia*, Bromeliaceae, *Typha*, or Graminae that are attached with cobweb; outer walls decorated with pieces of grey-red lichens; placed on a horizontal branch, usually 1-6 m above ground, occasionally up to 10 m. Clutch size 2; incubation 14 days, by female; fledging at 20-26 days, occasionally up to 32 days.

Movements. Generally sedentary, with some local movements.

Status and Conservation. Not globally threatened. CITES II. The southern races *versicolor* and *kubicheki* are more common and widespread than the northern representatives, except *millerii*. In Venezuela, *millerii* occurs almost exclusively south and east of the Orinoco, with only one record to the north in lower Orinoco basin (Monagas). Generally, distribution poorly understood as nearly all races show either unclear range limits or highly scattered distribution; as an example of the latter, race *hollandi* may be confined to a few valleys and tepuis of the SE Venezuelan highlands.

Bibliography. Abe *et al.* (1992), Bangs & Penard (1918), Barrowclough *et al.* (1997), Bech *et al.* (1997), Belton (1984), Berlioz (1934, 1964), Bond & Meyer de Schauensee (1943), Brooks *et al.* (1993), Burton (1971), Canevari *et al.* (1991), Cintra & Yamashita (1990), Friedmann (1948), Grantsau (1988), Griscom & Greenway (1941), Guix *et al.* (1992), Hartert (1899a), Hayes (1995), Hellmayr (1906, 1929), Hilty & Brown (1986), Lowen, Bartrina, Clay & Tobias (1996), Navas & Bo (1993), Nicéforo & Olivares (1967), Meise (1938), Meyer de Schauensee & Phelps (1978), Naumburg (1930), Oniki (1996), de la Peña (1994), do Rosário (1996), Ruschi (1959, 1967a, 1973d, 1981-1982, 1986), Saibene *et al.* (1996), Sánchez (1995), Sick (1993, 1997), Snow & Snow (1986), Stotz *et al.* (1996), Teixeira *et al.* (1987), Todd (1942), Viellard (1983, 1994), Willard *et al.* (1991), Willis (1992), Zimmer (1950f).

148. Blue-green Emerald

Agyrtia rondoniae

French: Ariane du Rondonia **German:** Blaugrünamazilie **Spanish:** Amazilia de Rondonia

Taxonomy. *Amazilia rondoniae* Ruschi, 1982, Porto Velho, Rondônia, Brazil.

Genus usually merged into *Amazilia*. Usually considered a race of *A. versicolor*, but on basis of reported sympatry without interbreeding, probably better considered a distinct species. Monotypic.

Distribution. Known only from right bank of R Madeira in WC Brazil (Rondônia) and N Bolivia.

Descriptive notes. 8.5-9.5 cm. Male has straight, short bill, upper mandible blackish, lower fleshy red with dark tip; crown, cheeks and chin azure blue; upperparts and flanks shining bronze-green; centre of underparts white; tail bronze-green with dark subterminal bars on outer rectrices. Female has more extensive turquoise green on neck sides; chin spotted bluish-green, due to broader white subterminal bars. Immature plumage unknown.

Habitat. Forests, *cerrado*, park-type landscapes along R Madeira at altitude of c. 100 m.

Food and Feeding. Forages for nectar at various trees and bushes like *Inga*; diet also includes tiny insects.

Breeding. No information available.
Movements. no information.

Status and Conservation. Not globally threatened. CITES II. Current status and distribution needs to be studied as population size and extent of range are unclear. Ecological requirements insufficiently known; perhaps threatened by deforestation, a situation that applies in particular to the Brazilian population.

Bibliography. Bahr (1995), Forrester (1993), Grantsau (1988), Hartert (1899a), Ruschi (1981-1982, 1982b, 1986), Sick (1993), Viellard (1994).

149. White-chested Emerald

Agyrtia brevirostris

French: Ariane à poitrine blanche

Spanish: Amazilia Pechiblanca

German: Kurzschnebelamazilie

Other common names: White-breasted Emerald

Taxonomy. *Ornismya brevirostris* Lesson, 1829, Guyana.

Genus usually merged into *Amazilia*. Species has normally been listed as *A. chionopectus*, as name *brevirostris* was believed to refer to *A. versicolor* with an erroneous type locality. With rectification of name and consequent revised type locality, race formerly listed as *whitelyi* becomes nominate, with name *whitelyi* as a synonym. Three subspecies recognized.

Subspecies and Distribution.

A. b. chionopectus (Gould, 1859) - Trinidad.

A. b. brevirostris (Lesson, 1829) - E Venezuela, Guyana, Surinam and extreme NC Brazil.

A. b. orienticola (Todd, 1942) - coastal French Guiana.

Descriptive notes. 9-10 cm; male 4-6 g, female 4-4 g. Male has straight, short, almost blackish bill; crown and cheeks iridescent turquoise green; upperparts shining bronze-green, becoming more copperish towards rump and tail; central underparts white; flanks and sides of chest bronze-green; undertail-coverts with golden green centres and white fringes; lateral tail feathers bronze to copperish, duller on upperside, with blackish subterminal bars below. Female has greyish tips on outer rectrices. Immature similar to female, but with yellowish to reddish base of lower mandible. Race *chionopectus* significantly larger in all

morphometric characters; *orienticola* has upperparts and flanks darker, more markedly bronze-coloured.

Habitat. Inhabits rainforest, semi-deciduous forest, and gallery forest, second growth, scrub, savanna and semi-cultivated land. On Trinidad, prefers more open valleys with plantations. Ranges from sea-level to 500 m; race *orienticola* apparently restricted to coastal habitats.

Food and Feeding. Forages for nectar at larger trees, including *Erythrina* and *Samanea*, smaller trees like *Calliandra*, herbs such as *Pachystachys*, and various species of Malvaceae, Leguminosae, Lorantaceae, Bignoniaceae, Vochysiaceae and Verbenaceae. Hunts for small insects in vegetation, or in the air by hawking.

Breeding. At least Dec-Apr. Nest cup-shaped, made of greyish plant fibres, decorated with lichen; placed on horizontal branch 1-7 m above ground. Clutch size 2; incubation by female; fledging period about 20 days.

Movements. No information available; most populations probably sedentary.

Status and Conservation. Not globally threatened. CITES II. Generally a common resident in semi-open, coastal areas. One of the commonest trochilids on Trinidad; adapts readily to man-made habitats. However, the status of some important mainland populations has not been studied recently, so there is no information on current abundance or potential threats. For example, race *orienticola* is considered to be very rare since only two specimens exist and there have been very few sightings; the most recent possible record was in 1987.

Bibliography. Bangs & Penard (1918), Belcher & Smoother (1936), Berlepsch (1908), Broom (1976), Chubb (1916), Deignan (1961), French (1991), Forrester (1993), Friedmann & Smith (1955), Grantsau (1988), Hartert (1899a), Haverschmidt (1955a), Haverschmidt & Mees (1994), Herklots (1961), Junge & Mees (1961), Meyer de Schauensee & Phelps (1978), Ruschi (1981-1982, 1986), Sargeant (1994a), Shingler (1969), Sick (1993, 1997), Snow & Snow (1972), Snyder (1966), Stotz *et al.* (1996), Tostain *et al.* (1992), Zimmer & Hilty (1997).

150. Andean Emerald

Agyrtia franciae

French: Ariane de Francia

German: Andenamazilie

Spanish: Amazilia Andina

Taxonomy. *Trochilus Franciae* Bourcier and Mulsant, 1846, Bogotá, Colombia.

Genus usually merged into *Amazilia*. Due to different crown colour, race *viridiceps* sometimes regarded as a separate species or treated as race of *A. versicolor*. "*A. veneta*" may be melanistic female of present species. Three subspecies recognized.

Subspecies and Distribution.

A. f. franciae (Bourcier & Mulsant, 1846) - NW & C Colombia.

A. f. viridiceps (Gould, 1860) - SW Colombia and W Ecuador.

A. f. cyanocollis (Gould, 1854) - Andes of N Peru.

Descriptive notes. 9-11 cm; male 5-6 g, female 5-3 g. Male has medium-sized, straight to slightly decurved bill, upper mandible blackish, lower coral red with dark tip; crown glittering violet-blue; cheeks and neck glittering golden to emerald green; rest of upperparts and flanks light to golden green, with more copperish tinge towards uppertail-coverts; centre of underparts white; tail bronze-green to copperish, sometimes with purplish tinge to inner rectrices. Female has crown less glittering, more turquoise blue to greenish. Immature male resembles female in crown coloration, also has brownish feather borders on entire upperparts; greyish

brown on flanks. Race *viridiceps* has green crown and significantly shorter tail; in race *cyanocollis*, crown patch extends to nape.

Habitat. Inhabits wet forest edges, second growth and clearings; in W Peru, also found in more arid, shrubby areas. Ranges in altitude from 600 to 2100 m; commonest above 1000 m, rarely in lowlands.

Food and Feeding. Forages for nectar at various heights, chiefly in middle to upper strata; may form feeding assemblies. Found at flowering herbs such as banana (*Musa*) or *Canna*, climbers like *Psammisia*, shrubs (*Hamelia*, *Cavendishia*), and trees, especially *Eugenia*. Trap-liner; often subordinate to territorial hummingbird species such as *Amazilia tzacatl* and *Saucerottia cyanifrons*. Occasionally hawks for insects in short sallies, close to or within vegetation.

Breeding. Almost all year round; birds in breeding condition have been recorded in Apr, May, Oct, Dec. Nest cup-shaped, fixed with cobweb, covered on outside with lichen. Clutch size 2; incubation by female; chick flesh-coloured, with buff down; no data exist on incubation and fledging periods.

Movements. Seasonal changes in altitude indicated by absence from breeding areas such as Anchicayá (SW Colombia), and by a few lowland records (e.g. in Colombia, at R Zapato).

Status and Conservation. Not globally threatened. CITES II. Fairly common to uncommon, but status of local populations poorly known. Abundance in certain places may vary with flowering season of plants. Present in La Planada Reserve, Nariño (S Colombia).

Bibliography. Becker & López (1997), Berlioz (1937), Best *et al.* (1997), Butler (1979), Chapman (1917, 1926), Davies *et al.* (1994), Grummi (1975), Hartert (1899a), Hilty (1977, 1997), Hilty & Brown (1986), Kirwan & Marlow (1996), Meise (1938), Meyer de Schauensee (1949, 1964, 1982), Miller (1963), Mobbs (1972c), Parker *et al.* (1982), Rutgers & Norris (1972), Salaman & Mazariegos (1998b), Snow & Snow (1980), Stotz *et al.* (1996), Warren (1966), Williams & Tobias (1994), Zimmer (1950f).

151. White-bellied Emerald

Agyrtia candida

French: Ariane candide

German: Bronzekopfamazilie

Spanish: Amazilia Cándida

Taxonomy. *Trochilus candidus* Bourcier and Mulsant, 1846, Cobán, Guatemala.

Genus usually merged into *Amazilia*. Race *genini* has been questioned on the basis of some intergradation with nominate in E Mexico. Three subspecies recognized.

Subspecies and Distribution.

A. c. genini Meise, 1938 - E to S Mexico.

A. c. pacifica Griscom, 1929 - SE Mexico (S Chiapas) and S Guatemala.

A. c. candida (Bourcier & Mulsant, 1846) - SE Mexico (Yucatán Peninsula) and Belize through N Guatemala and Honduras to Nicaragua.

Descriptive notes. 9-11 cm; male 3-8 g, female 3-4 g. Male has straight, short bill, blackish except for pinkish basal part of lower mandible; crown dark bronze-green; upperparts shining golden to bronze-green; throat, centre of underparts, and undertail-coverts white; tail bronze-green, dark subterminal band on outer rectrices. Female differs from male in spotted sides of throat and greyish tips to tail feathers. Immature has grey-brownish belly. Race *genini* has significantly longer, slightly broader bill; *pacifica* has longer, broader bill and longer wings.

Habitat. More confined to forests than most other congeners. Inhabits rainforest and cloudforest, wooded riverbanks, clearings, coffee and banana plantations. Nominates race and *genini* occur from sea-level to 1500 m, but mostly in the lower sub-montane zone below 1000 m; race *pacifica* found between 400 and 1000 m.

Food and Feeding. Diet includes nectar and small insects. Found in all strata; in forest interiors at tree tops, at lower levels outside forests. Food plants include trees like *Inga micheliana*, *Miconia trinervia* and *Trichospermum*, shrubs such as *Cephaelis* or *Hamelia*, and herbs (*Heliconia*); seasonal trap-lining recorded. Sometimes seen in groups with congeners, or together with other species; partially subordinate to *Amazilia tzacatl* among other species.

Breeding. In Mexico, laying has been reported Apr-May. However, breeding probably starts in Feb when singing activity occurs; birds in breeding condition have been observed until Sept. Nest cup-shaped, made of soft plant down and fibres; placed on a horizontal branch. One nest was found 2 m up in a *Guettarda* tree. Clutch size 2; incubation by female; no data exist on duration of incubation or fledging.

Movements. Wintering birds of the northern populations have been recorded from the Pacific slope of Oaxaca and Chiapas (Mexico). Wintering habitats include swamps and semi-deciduous forests. Strong seasonal movements are found in Oaxaca, where breeders occur in large numbers in lowland tropical evergreen forests from mid-Feb to Jul in the Atlantic region, where less common from mid-Jul to Nov, and absent in winter. Race *candida* accidental to Costa Rica; any have bred there in past, but no recent records.

Status and Conservation. Not globally threatened. CITES II. Common in the tropical lowlands along the Caribbean slope. Uncommon to rare at higher elevations and on the Pacific slope. Race *pacifica* restricted to scattered lowland and sub-montane rainforests in SE Mexico and S Guatemala; has suffered from extensive deforestation. Establishment of forest reserves appears necessary to protect remnant populations. Current status in Costa Rica unclear; a few older specimen records may indicate occurrence, at least formerly, as rare breeding species.

Bibliography. Andrie (1967), Atwood *et al.* (1991), Binford (1989), Bjelland & Ray (1977), Blake (1950a), Davis (1972), Dearborn (1907), Edwards & Tashian (1959), Feinsinger (1976), Friedmann *et al.* (1950), Griscom (1934), Hartert (1899a), Howell & Webb (1992a, 1995a), Johnson (1997), Land (1963a, 1963b, 1970), Lowery & Dalquest (1951), Lynch (1992), Meise (1938), Monroe (1968), Noctedal (1981), Paynter (1957), Phillips (1964), Ridgway (1911), Russell (1964), Rutgers & Norris (1972), Slud (1964), Smith & Paynter (1963), Stiles & Skutch (1989), Stotz *et al.* (1996), Sutton & Burleigh (1940), Tashian (1953), Wagner (1957b).

152. Azure-crowned Hummingbird

Agyrtia cyanocephala

French: Ariane à couronne azur

German: Blaukopfamazilie

Spanish: Amazilia Coroniazul

Other common names: Red-billed Azurecrown; Mosquitia Hummingbird (*chlorostephana*)

Taxonomy. *Ornismya cyanocephalus* Lesson, 1829, Brazil; error = Veracruz, Mexico.

Genus usually merged into *Amazilia*. Race *chlorostephana* has been suggested as possibly approaching species status, but nominate (in E of range) shows clinal variation in crown colour to-

wards *chlorostephana*. Birds from Belize S to N Nicaragua formerly separated as race *guatemalensis*, but specimens from C & E Guatemala, including type locality of *guatemalensis*, Dueñas, show strong intergradation with nominate birds from Chiapas (S Mexico). Proposed species "A. *microrhyncha*" (Honduras, Nicaragua), known from two specimens and separated in part on basis of unusually short bill, does not merit even subspecific recognition because characters appear to be based on individual variation or juvenile, probably of nominate. Two subspecies recognized.

Subspecies and Distribution.

A. c. cyanocephala (Lesson, 1829) - E & S Mexico to E Honduras and NC Nicaragua.

A. c. chlorostephana (Howell, 1965) - Mosquito Coast of E Honduras and NE Nicaragua.

Descriptive notes. 10-11 cm; male 5-8 g, female 5-2 g. Male has straight, medium-sized bill, upper mandible blackish, lower reddish with dark tip; crown glittering turquoise to violet-blue; back, rump and flanks golden green to bronze-green; centre of underparts white; undertail-coverts chiefly bronze-green with white fringes; tail greyish-green to bronze-green. Female has more turquoise reflections on crown and neck. Immature has feathers of upperparts tipped rufous; less white on underparts, belly more greyish-brown; immature male strongly resembles female in crown coloration. Race *chlorostephana* has metallic green to turquoise green crown, rarely approaching the turquoise coloration of nominate female; significantly smaller in all measurements.

Habitat. Inhabits pine and pine-oak forest, cloudforest and rainforest, edges of humid forest; also found in gallery forest, savanna, brush, abandoned fields and gardens. Races differ in altitudinal distribution; nominate race occurs regularly between 500 and 1800 m, occasionally up to 2400 m, rarely close to sea-level, for example in N Honduras. Range of race *chlorostephana* below 100 m, since tied to distribution of pine savanna (with *Pinus caribaea*); inhabits stands of pine close to gallery forest and edges of isolated evergreen rainforest.

Food and Feeding. Feeds on nectar, especially at flowering epiphytes. Hovers briefly; feeds in all strata, but mainly at 4-6 m above ground; in gallery forests, forages in streamside vegetation. Sometimes concentrates in groups at flowering *Inga* trees. Hunts aerially for insects.

Breeding. Varies with region; in Mexico, Feb-Aug; in Belize, Jan-Jul; in Guatemala, data on gonadal activity indicate Jul-Sept; in Nicaragua, breeding recorded Feb. Nest an open cup, with moss, plant fibres, pieces of lichen; placed on horizontal branch or fork, up to 15 m above ground. Clutch size 2; incubation by female; no data exist on duration of incubation or fledging.

Movements. Some populations are sedentary, for instance in Veracruz and San Luis Potosí (Mexico), whereas others are migratory. Larger numbers of wintering birds in Mexico occur along the Pacific coast of Oaxaca and Chiapas, also in the Atlantic lowlands of Guatemala and Honduras. Vagrants reach northern parts of Yucatán Peninsula. In general, altitudinal seasonality noted, with breeding ranges at higher elevations and preference for foothills and lowlands in non-breeding season.

Status and Conservation. Not globally threatened. CITES II. Common in pine and pine-oak forests of the highlands of interior Mexico, Guatemala and Honduras, rarer in cloudforest and lowland rainforest. Race *chlorostephana* of lowland pine savanna of Mosquitia, is rather uncommon and local; however, has profited from habitat alteration by man, as the decline of the original low-elevation woodlands enabled the spread of the open savanna type.

Bibliography. Anon. (1998a), Berlioz (1932b), Binford (1989), Bjelland & Ray (1977), Brown & Bowers (1985), Davis (1944, 1952), Dickey & van Rossem (1938), Edwards & Lea (1955), Friedmann *et al.* (1950), González-García (1993), Hartert (1899a), Howell, S.N.G. & Webb (1995a), Howell, T.R. (1965, 1972), Johnsgard (1997), Land (1963a, 1970), Lowery & Dalquest (1951), Martins *et al.* (1954), Monroe (1968), Phillips (1964, 1971), Rand & Traylor (1954), Ridgway (1911), Rowley (1984), Russell (1964), Siotz *et al.* (1996), Thurber *et al.* (1987), Todd (1942), Udvardy (1983), Wagner (1957b), Wetmore (1941).

153. Violet-crowned Hummingbird

Agrytria violiceps

French: Ariane à couronne violette

Spanish: Amazilia Coronivioleta

German: Veilchenscheitelamazilie

Other common names: Azurecrown, Salvin's Hummingbird

Taxonomy. *Cyanomyia violiceps* Gould, 1859, Atlitico, Puebla, Mexico.

Genus usually merged into *Amazilia*. Forms a superspecies with *A. viridifrons*, with which formerly considered conspecific. Species name sometimes given as *verticalis*, but this name refers to *A. cyanocephala*. Proposed race *conjuncta*, of Sonora, indistinguishable from *elliotti*. "*Cyanomyia salvini*", from Nacosari (Sonora), reported to be of hybrid origin with *Cyananthus latirostris*, but is probably an aberrant individual of race *elliotti*. Two subspecies recognized.

Subspecies and Distribution.

A. v. elliotti (Berlepsch, 1888) - extreme SW USA to NW & C Mexico.

A. v. violiceps (Gould, 1859) - SW Mexico.

Descriptive notes. 10 cm; 5.0 g. Male has straight, medium-sized bill, fleshy red except for dark tip; crown violet-blue; upperparts and flanks olive green to bronze-green; undertail-coverts bronze to coppery, sometimes with purplish tinge; underparts entirely white; inner rectrices bronze to purplish. Female has crown and neck more turquoise. Immature crown resembles that of female, but feathers bordered with rufous; bill more blackish above; greyish borders in rump and upperpart-coverts. Race *elliotti* has crown more turquoise bluish, the coloration extending to neck and cheeks; inner rectrices greyish golden-green.

Habitat. Inhabits semi-open to open arid scrubland, thorn forests, open pine and pine-oak forests, forest edges, riparian groves, plantations, parks and gardens. Ranges from near sea-level to 2250 m, but chiefly at 1000-1500 m.

Food and Feeding. Forages for nectar mainly in middle to upper strata; recorded for example at *Agave*. Insects are caught in the air by hawking.

Breeding. Mainly Apr-Aug, but nesting and birds in breeding condition have been observed until Jan. Cup-like nest, consisting of plant material such as cotton-like fibres and green lichen, fixed with cobweb; usually placed on dead twig, horizontal branch or tip of overhanging branch. In Guadalupe Canyon, USA, nests found at heights of 7-12 m in sycamore trees (*Platanus wrightii*); nests in Mexico located in shrubs or small oak trees 1-2 m above ground. Clutch size 2; incubation by female; no data exist on incubation and fledging periods.

Movements. Partially migratory. Northernmost populations probably winter along N Pacific slope from SE Sonora southward, and on Atlantic slope from Guanajuato to Hidalgo; earliest summering birds in Sonora can be observed regularly in Mar, although there are indications of overwintering individuals. Representatives of race *violiceps* mostly occur in winter along the S Pacific slope from Guerrero to Oaxaca; latest summering individuals reported in October. Recent spring and breeding season records from California indicate overwintering birds or even migrational trends that could establish a new breeding population in W USA.

Status and Conservation. Not globally threatened. CITES II. Common to uncommon resident throughout range. Race *elliotti* occurs very locally in SE Arizona and SW New Mexico, where confined to the riparian vegetation of Guadalupe Canyon; rarely found in NE Sonora, more common in southern parts of range. Nominative race is a more frequent breeder in the interior parts of SC Mexico than in the coastal regions.

Bibliography. Anon. (1998a), Baicich & Harrison (1997), Baltosser (1986a, 1989b), Bent (1940), Berlioz (1932a, 1932b), Binford (1989), Bishop (1906), Brewster (1893), Cisneros & Bonilla (1993), Davis (1944), DeGraaf & Rappole (1995), Des Granges & Grant (1980), Edwards & Lea (1955), Eguarte *et al.* (1987), Friedmann *et al.* (1950), Gray (1958), Hartert (1899a), Howell & Webb (1995a), Johnsgard (1997), Johnson, J.A. & Ziegler (1978), Johnson, T.B. (1987), Johnston & Hardy (1959), Kaufman (1996), Lasiewski & Lasiewski (1967), Levy (1958), Ligon (1961), McCaskie (1976, 1987), Phillips (1964), Ridgway (1911), Rising (1965), van Rossem (1945a), Rowley (1966), Selander & Giller (1959), Sheppard (1968), Short (1974), Simon (1911), Storer (1961), Stotz *et al.* (1996), Stresemann (1954), Wagner (1957a), Wetmore (1943), Yee *et al.* (1992), Zimmerman & Levy (1960).

154. Green-fronted Hummingbird

Agrytria viridifrons

French: Ariane à front vert

German: Grünscheitelamazilie

Spanish: Amazilia Freniverde

Other common names: Cinnamon-sided Hummingbird (*wagneri*)

Taxonomy. *Cyanomyia viridifrons* Elliot, 1871, Putla de Guerrero, Mexico.

Genus usually merged into *Amazilia*. Forms a superspecies with *A. violiceps*. Until mid-20th century, holotype of present species was believed to represent an aberrant individual of *A. violiceps*, due to sexual and age-related variation in coloration of crown in both species; in addition, forms described as "*Cyanomyia guerrensis*", "*Uranomitra dermeddei*" and "*U. atricapilla*" all refer to present species but were earlier considered synonyms of *A. violiceps*; when finally recognized as a valid taxon, present species was considered a race of *A. violiceps*; recent morphological and biogeographical studies, however, including discovery of zone of sympatry in Guerrero but no known hybridization, confirm validity of present species. Race *wagneri* sometimes considered a separate species, but morphological differences slight. Birds from C Oaxaca have been awarded race *rowleyi*, but probably not valid, due to strong intergradation of nominate and race *wagneri* in zone of supposed secondary contact. Nominative race shows disjunct distribution, with gap in E Oaxaca. Two subspecies recognized.

Subspecies and Distribution.

A. v. viridifrons (Elliot, 1871) - S Mexico: E Guerrero to W Oaxaca; E Oaxaca to C Chiapas.

A. v. wagneri (Phillips, 1964) - S Mexico: C & S Oaxaca.

Descriptive notes. 10-11.5 cm; 5.5 g. Male has straight, medium-sized bill, flesh red with dark tip; crown dark-coloured, appears blackish from a distance but glittering oily to bluish-green close up; nape, mantle and sides of breast emerald to bronze-green; rump and upperpart-coverts greyish-brown to bronze; chin, throat and centre of belly white; flanks bronze-green, sometimes with pale cinnamon to vinaceous spots; undertail-coverts white, centres often with cinnamon to vinaceous spots or streaks; rectrices coppery to purplish, edged with bronze-green. Female has crown dark green; tail less coppery, bronze to gold-green. Immature shows pale cinnamon feather tips on upperparts and rectrices; immature male has crown coloration similar to female. Race *wagneri* has cinnamon flanks and sides, and cinnamon-rufous bases to secondaries and inner primaries.

Habitat. Resident of temperate arid to semi-arid, open pine-oak forest, oak scrub, thorn forest; sometimes found at edges of humid forest, in riparian woodland, parks and gardens. Western population of the nominate race recorded between 730 and 1400 m, whereas eastern population found down to 60 m; race *wagneri* ranges from 250 to 900 m.

Food and Feeding. Forages for nectar at flowering bushes and trees from middle to upper strata; diet includes small insects which are caught by hawking.

Breeding. Data on nesting and gonadal activity from Oaxacan birds indicate Dec-May, Aug-Oct; for Chiapas, at least Apr-Jun. Nest cup-shaped, made of plant-wool and lichen, fixed with cobweb, 2-3 m above ground. Clutch size 2, eggs often appearing stained due to washing out of nest material by rain; incubation by female; no further information available.

Movements. Generally sedentary with some local movements, as indicated by altitudinal shifts in distribution of post-breeders towards lower elevations. Nominative birds may occasionally occur along the Atlantic coast of Yucatán as indicated by one record from Belize. Status in extreme W Guatemala uncertain, but species may be resident.

Status and Conservation. Not globally threatened. CITES II. Fairly common in the arid tropical zone of the Sierra Madre del Sur and the Sierra Madre de Chiapas. In Guerrero, mainly found in Rio Balsas drainage; in Oaxaca, mostly recorded from Rio Grande drainage, but also found in tributaries of Rio Verde, and S of Sierra de Miahuatlán. Eastern population of nominate *viridifrons* is common resident from Pacific slope foothills of extreme E Oaxaca to interior Chiapas (Grijalva Valley), but apparently absent from Pacific slope of Sierra Madre de Chiapas.

Bibliography. Anon. (1998a), Berlioz (1932b), Binford (1989), Davis (1972), Friedmann *et al.* (1950), Hartert (1899a), Howell (1993c), Howell & Webb (1995a), Johnsgard (1997), Phillips (1964), Ridgway (1911), Rowley (1966, 1984), Schuchmann (1990b), Simon (1911), Stotz *et al.* (1996), Wetmore (1947).

Genus *POLYERATA* Heine, 1863

155. Glittering-throated Emerald

Polyerata fimbriata

French: Ariane de Linné **German:** Glitzerkehlamazilie **Spanish:** Amazilia Listada

Taxonomy. *Trochilus fimbriatus* J. F. Gmelin, 1788, Cayenne.

Genus sometimes lumped into *Agyrtia*; these two usually merged into *Amazilia*. Forms a superspecies with *P. lactea*. Races *fluvialis*, *nigricauda* and *tephrocephala* were all previously treated as distinct species. Several proposed races are invalid due to similar morphology and range overlap with adjacent forms: *obscuricauda* has proved to be identical to *elegantissima*; *maculicauda* and *alia* are inseparable from nominate race. In Táchira, Venezuela, the very local "*Amazilia distans*" is most probably of hybrid origin, present species x *Hylocharis cyanus*. "*P. cyaneotincta*", known only from two skins of uncertain origin, has been suggested to be aberrant form of present species, but this seems unlikely; in plumage pattern more similar to *P. amabilis*. Seven subspecies currently recognized.

Subspecies and Distribution.

P. f. elegantissima (Todd, 1942) - extreme NE Colombia and N & NW Venezuela.

P. f. fimbriata (J. F. Gmelin, 1788) - NE Venezuela from Orinoco basin to the Guianas and N Brazil N of Amazon.

P. f. apicalis (Gould, 1861) - Colombia E of Andes.

P. f. fluvialis (Gould, 1861) - SE Colombia and E Ecuador.

P. f. laeta (Hartert, 1900) - NE Peru.

P. f. nigricauda (Elliot, 1878) - E Bolivia and C Brazil S of Amazon.

P. f. tephrocephala (Vieillot, 1818) - coastal SE Brazil from Espírito Santo to Rio Grande do Sul.

Descriptive notes. 8-12 cm; 4-6 g. Male has straight, medium-sized bill, upper mandible blackish, lower pinkish, tipped dark; upperparts golden to bronze-green; throat and breast glittering golden green, rarely with turquoise sheen; centre of lower breast, belly white; undertail-coverts white with brownish centres; tail dark bronze-green to blackish-bronze. Female with white subterminal bars on throat feathers; outermost rectrices have greenish-grey tips. Immature has whitish on belly reduced, more greyish-brown. Race *elegantissima* has coppery to purplish upperpart-coverts; *apicalis* has significantly longer bill; *fluvialis* and *laeta* show turquoise to bluish sheen on throat, and *fluvialis* has significantly longer bill; *nigricauda* and *tephrocephala* have pure white undertail-coverts and greenish-black to bluish-black tail; *tephrocephala* is slightly heavier, and significantly larger in all morphometric characters.

Habitat. Generally widespread in open to semi-open areas; normally absent from interior of dense forest. Present in a great variety of habitats, including dry and humid forests, forest edges, gallery forest, second growth, open woodland, savanna, scrub, plantations and gardens. In central parts of Brazil, a typical bird of the *caatinga* and *capoeira*; also inhabits mangroves along the Atlantic coast. Ranges from sea-level to 1100 m, mainly below 500 m.

Food and Feeding. Mostly feeds in lower strata of flowering trees, often close to ground, and takes nectar also while perching; trap-liner. Forages for nectar at a great variety of native and introduced plant families and species, among them Bromeliaceae, Leguminosaceae, Passifloraceae, Heliconiaceae, Malvaceae, Proteaceae, Cactaceae and Rubiaceae; in gardens, often at flowering herbs and bushes, such as *Malvaviscus*, *Azibulon*, *Genipa*, or *Stachytarpheta*, trees like *Inga* and *Citrus*, or climbers like *Thunbergia*. Also hunts for insects such as small flies (Diptera) and beetles.

Breeding. Almost all year round; in Guyana and NE Brazil, data indicate Aug-Sept, in Argentina, Paraguay and Uruguay Nov-Dec. Nest cup-shaped, placed on horizontal branch, rarely in fork; consists of plant wool, cobweb, lichen; usually found low down, mostly below 4 m, sometimes less than 1 m, occasionally up to 8 m. One nest of race *nigricauda* was placed in a shrub, and made of *Typha* and Bromeliaceae kopak and compound leaves. Nest-building takes 6-12 days. Clutch size 2; incubation 14-17 days, by female; chick darkish, with sparse buff dorsal down; fledging at 18-22 days. Two broods or more possible per year.

Movements. Race *tephrocephala* migrates regularly southward along Atlantic coast, occasionally reaching Rio Grande do Sul. Other races probably make only very local movements, though not well known.

Status and Conservation. Not globally threatened. CITES II. Common to very common in many parts of the range, especially within northern and eastern regions. Has been erroneously reported once from Trinidad. Current distributional limits of populations E of Andes from Venezuela to Peru poorly known. Race *tephrocephala* is locally common breeder in SE Brazil, but generally uncommon along Atlantic coast; despite its occupation of open areas, species has presumably suffered from destruction of coastal forest. Form "*distans*", probably of hybrid origin, has been classed as Endangered.

Bibliography. 156. Sapphire-spangled Emerald

Polyerata lactea

French: Ariane saphirine **German:** Saphiramazilie **Spanish:** Amazilia Zafirina
Other common names: Tepui Emerald (*zimmeri*); Bartlett's Emerald (*bartletti*)

Taxonomy. *Ornismya lactea* Lesson, 1832, the Guianas and Brazil.

Genus sometimes lumped into *Agyrtia*; these two usually merged into *Amazilia*; present species has alternatively been placed in *Hylocharis*. Forms a superspecies with *P. fimbriata*. The three races show highly disjunct distribution; race *bartletti* sometimes treated as a separate species; *zimmeri* too has been more tentatively suggested as sufficiently distinctive to merit splitting as a further species. Three subspecies currently recognized.

Subspecies and Distribution.

P. l. zimmeri (Gilliard, 1941) - SE Venezuela.

P. l. bartletti (Gould, 1866) - E & SE Peru and N Bolivia; doubtfully extreme E Ecuador.

P. l. lactea (Lesson, 1832) - C & S Brazil from S Bahia to São Paulo.

Descriptive notes. 8-11 cm; male 4-0 g, female 3-6 g. Male has straight, medium-sized bill, upper mandible blackish, lower pinkish to horn-coloured with greyish tip; crown, neck, and flanks bronze-green; rest of upperparts golden to bronze-green; throat, upper breast glittering violet-blue; centre of breast white, belly greyish, undertail-coverts whitish with brown basal streak; median rectrices basally shining green, laterally as outer rectrices bluish-black. Female has throat more greyish, with discs rather glittering turquoise than violet; outermost rectrices with greyish tips. Immature has extended greyish areas on underparts; immature male resembles adult female in throat coloration. Race *zimmeri* is distinguished by reduction of violet patch on throat, with greyish-fringed feathers; *bartletti* is characterized by longer bill and wings, more conspicuous greyish fringing on throat, greenish centre of belly, below greyish, undertail-coverts with prominent brown centres.

Habitat. Inhabits edges of rainforest, gallery forest, second growth and clearings; particularly in south of range often found in open to semi-open habitats such as *capoeiras*, parks, orchards, gardens, etc. Normally occurs below 1000 m, rising to 1400 m in Pantepui area of Venezuela and submontane zone of Peruvian Andes; Brazilian population close to sea-level.

Food and Feeding. Forages for nectar at a great variety of native and introduced plants; some preferred plant families are Leguminosaceae, Malvaceae, Heliconiaceae and Rubiaceae. In parks and suburban areas often found at flowering shrubs and trees, such as *Inga*, *Citrus*, *Eucalyptus*, or *Genipa*. Male establishes feeding territory. Insects are caught in the air by hawking.

Breeding. Southern populations breed Oct-Jan at least; season of Venezuelan birds unknown. Nest cup-shaped, built of plant down, cobweb, outside covered with lichens. One nest in Bolivia constructed 2 m up in papaya tree. Clutch size 2; incubation 14 days, by female; chick darkish, with some buff dorsal down; fledging period 22 days.

Movements. Southern populations are short-distance migrants; nothing is known on movements of northern population.

Status and Conservation. Not globally threatened. CITES II. Common to very common in western and eastern parts of range notably in Brazil, where occurs in several protected areas, e.g. Serra dos Órgãos and Itatiaia National Parks (Rio de Janeiro) and Serra do Cipó National Park (Minas Gerais). Current distribution and population size in Venezuela requires confirmation, where race *zimmeri* is very local and disjunct in range and known only from three collecting sites in Bolívar, the northernmost, Auyán Tepui, is located in Canaima National Park.

Bibliography. dos Anjos *et al.* (1997), Berlepsch & Stolzmann (1902), Berlioz (1965), Bond & Meyer de Schauensee (1943), Boucard (1892a), Brace *et al.* (1997), Cintra & Yamashita (1990), Donahue (1994), Gilliard (1941), Grantsau (1988), Gyldenstolpe (1945b), Meyer de Schauensee (1966), Meyer de Schauensee & Phelps (1978), Niethammer (1953), Oniki (1996), Parker *et al.* (1982), Remsen & T aylor (1989), do Rosário (1996), Ruschi (1949a, 1953b, 1981-1982, 1986), Sánchez (1995), Sick (1993, 1997), da Silva (1996), Snow & Teixeira (1982), Stotz *et al.* (1996), Terborgh *et al.* (1984), Willis (1992), Zimmer (1950f).

157. Blue-chested Hummingbird

Polyerata amabilis

French: Ariane aimable **German:** Blaubrustamazilie **Spanish:** Amazilia Amable
Other common names: Blue-breasted/Beryl-crowned/Lovely Hummingbird; Charming Hummingbird (*decora*)

Taxonomy. *Trochilus* (—?) *amabilis* Gould, 1853, Colombia.

Genus sometimes lumped into *Agyrtia*; these two usually merged into *Amazilia*. Race *decora* sometimes considered a separate species, on grounds mainly of morphological differences, combined with distribution. Proposed race *costaricensis* (Nicaragua to Panama) inseparable from nominate. Two subspecies recognized.

Subspecies and Distribution.

P. a. amabilis (Gould, 1853) - NE Nicaragua to NC Colombia and Ecuador W of Andes; possibly SE Honduras.

P. a. decora Salvin, 1891 - Pacific slope from SW Costa Rica to W Panama.

Precise limits of range uncertain in NE Nicaragua and S Ecuador, and perhaps elsewhere.

Descriptive notes. 7-11 cm; male 4-1 g, female 3-8 g. Male has straight, medium-sized, blackish bill, lower mandible basally reddish; crown and malar area glittering green with slight bluish tinge; upperparts and flanks dull green to bronze-green; chin centrally bronzy; lower throat and breast with violet-blue patch and greyish-edged discs; lower belly greyish-brown; undertail-coverts with brownish centres; upperpart-coverts and tail bronze-green, rarely dull green, with some purplish reflections in the tail-coverts and median rectrices; outer rectrices becoming blackish. Female lacks glittering crown; instead of distinct throat patch has scattered turquoise to bluish feathers with

On following pages: 158. Purple-chested Hummingbird (*Polyerata rosenbergi*); 159. Mangrove Hummingbird (*Polyerata boucardi*); 160. Honduran Emerald (*Polyerata luciae*); 161. Steely-vented Hummingbird (*Saucerottia saucerottiei*); 162. Indigo-capped Hummingbird (*Saucerottia cyanifrons*); 163. Snowy-breasted Hummingbird (*Saucerottia edwardi*); 164. Blue-tailed Hummingbird (*Saucerottia cyanura*); 165. Berylline Hummingbird (*Saucerottia beryllina*); 166. Green-bellied Hummingbird (*Saucerottia viridigaster*); 167. Copper-tailed Hummingbird (*Saucerottia cupreicauda*); 168. Copper-rumped Hummingbird (*Saucerottia tobaci*).

broad whitish margins; belly paler; rectrices with greyish tips. Immature resembles female in throat coloration but more greyish in underparts. Race *decora* has longer bill and wings; glittering green of crown extends further back towards nape, upperparts average duller.

Habitat. Inhabits forest edges, open woodland, thickets, second growth, clearings, riparian vegetation, plantations, etc.; visits gardens with flowering trees. Generally commoner in open areas; avoids interior of dense forest. Occurs from sea-level to 1400 m; nominate race normally below 500 m and infrequent above 1000

m; race *decora* prefers lowlands as well as sub-montane zones of the slopes of Cordillera de Talamanca and Cordillera Central, and is encountered more often at medium elevations than nominate.

Food and Feeding. Forages for nectar, usually in lower strata at herbs such as *Heliconia* and shrubs; occasionally higher up in middle strata. In Colombia, recorded at diverse tree species, including *Inga*, *Bravasia* and *Hamelia*. Feeds by trap-lining or defends feeding territories that are different from those established during courtship.

Breeding. In Costa Rica, nesting starts with dry season from Dec to May; similar season assumed for Panama and Colombia. Cup-shaped nest on horizontal, leafy branch, in bush or small tree 2-5 m above ground; fixed with light-coloured plant fibres and cobweb; inside sometimes covered with seed-down and brown fern scales, outside with lichen and moss. Clutch size 2; incubation by female; chick flesh-coloured, with sparse buff dorsal down; no data exist on incubation and fledging periods.

Movements. Short-distance migrant; movements partially correlated with flowering period. Seasonal movements appear erratic, as individuals suddenly appear or disappear in certain places. May occur at higher altitudes after breeding season.

Status and Conservation. Not globally threatened. CITES II. Relatively common, at least locally, in most parts of range. One of the commonest trochilids in the Canal Zone. Race *decora* sometimes considered full species and classified as restricted range species: present in South Central American Pacific Slope EBA; in Costa Rica, this race occurs in several protected areas, e.g. Manuel Antonio and Corcovado National Parks and Golfito National Wildlife Refuge.

Bibliography. Bertin & Wilzbach (1979), Blake & Loisel (1991), Brosset (1964), Butler (1932a, 1932b), Eudes-Deslongchamps (1881), Gill *et al.* (1982), Gray (1958), Haffer (1975), Hartert (1898), Hilty (1985), Hilty & Brown (1986), Howell (1957), Karr (1977), Marcus (1983), Ridgely & Gwynne (1989), Rutgers & Norris (1972), Salaman & Mazariegos (1998b), Skutch (1958, 1966, 1972), Slud (1964), Stiles (1980, 1995b), Stiles & Skutch (1989), Stotz *et al.* (1996), Wetmore (1968a), Williams & Tobias (1994), Willis & Eisenmann (1979).

158. Purple-chested Hummingbird

Polyerata rosenbergi

French: Ariane de Rosenberg **German:** Rosenbergamazilie **Spanish:** Amazilia de Rosenberg
Other common names: Rosenberg's Emerald

Taxonomy. *Polyerata rosenbergi* Boucard, 1895, Río Dagua, Colombia.

Genus sometimes lumped into *Agyrtia*; these two usually merged into *Amazilia*. Proposed race *reini* (NW Ecuador) separated on basis of extent of breast patch, different throat coloration and longer bill, but these traits are attributable to individual variation. Monotypic.

Distribution. W Colombia and NW Ecuador.

Descriptive notes. 8-10 cm; male 4.0 g, female 3.5 g. Male has straight, medium-sized bill, upper mandible blackish, lower fleshy red except for dark tip; upperparts golden to dark golden green; uppertail-coverts bronze-green to purplish; underparts golden green, with violet-blue patch on upper breast; belly brownish, undertail-coverts pure white; central rectrices bronze to purple-green, outer rectrices more blackish-green. Female lacks the breast patch but exhibits an indistinct band of turquoise to bluish feathers with whitish margins; belly paler greyish; rectrices tipped white. Immature resembles female in throat-patch coloration.

Habitat. Rainforest, forest edges, second growth and clearings; occurs from near sea-level to 200 m. **Food and Feeding.** Forages for nectar at a great variety of plants, and feeding has been recorded from *Costus*, *Heliconia*, Ericaceae (*Macleania*, *Psammisia*), Gesneriaceae (*Allopectus*, *Besleria*, *Drymonia*, *Gasteranthus*) and Loranthaceae (*Tristerix*).

Breeding. Jan-Apr. Nest tiny, cup-shaped, made of soft plant fibres and lichen; built in low trees and vines, 2-4 m above ground. Clutch size 2; incubation 15-17 days, by female; chick darkish, with some buff dorsal down; fledging at 20-24 days.

Movements. Some local dispersal, but movements poorly understood.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species: present in Chocó EBA. Locally common resident. In coastal SW Colombia, recorded density of at least 2-3 pairs/km². Present in Río Nambi Reserve, Colombia.

Bibliography. Best *et al.* (1997), Butler (1979), Chapman (1917, 1926), Hartert (1898), Hellmayr (1911), Hilty & Brown (1986), Meyer de Schauensee (1982), Olrog (1968), Salaman & Mazariegos (1998b), Stotz *et al.* (1996).

159. Mangrove Hummingbird

Polyerata boucardi

French: Ariane de Boucard **German:** Mangrovenamazilie **Spanish:** Amazilia de Manglar
Other common names: Boucard's Hummingbird

Taxonomy. *Arena Boucardi* Mulsant, 1877, Puntarenas, Costa Rica.

Genus sometimes lumped into *Agyrtia*; these two usually merged into *Amazilia*; species alternatively placed in *Lepidopyga*. Forms a superspecies with *P. luciae*. Monotypic.

Distribution. Pacific coast of Costa Rica from Gulf of Nicoya to Gulf of Dulce.

Descriptive notes. 10-11 cm; 4-5 g. Male has slightly decurved, medium-sized bill, upper mandible blackish, lower reddish, distally dusky grey; upperparts and flanks golden to bronze-green; throat and breast glittering bluish-green, feathers towards chin with prominent white subterminal

bars; belly whitish, with bronze-green sides; undertail-coverts white; tail slightly forked, with almost blackish lateral and terminal portions on outer rectrices. Female white below, sides of throat spangled with some bluish-green spots; outermost rectrices with greyish tips. Immature male resembles female in throat coloration; more greyish below than adult.

Habitat. Chiefly mangroves with extensive stands of Pacific mangrove (*Pelliciera rhizophorae*), and sometimes in neighbouring second growth, often on sandbars; exclusively at or close to sea-level.

Food and Feeding. Nectar of various native and introduced plants; in addition to *Pelliciera*, visits adjoining vegetation including trees like *Lonchocarpus*, epiphytes and vines. Hunts aerially for mosquitoes.

Breeding. Oct-Feb. Nest has form of a small cup; consists of balsa floss, plant down, cobweb, with lichens on outside wall; usually placed on mangrove twigs, overhanging water, 1-4 m up. Clutch size 2; incubation by female; no data exist on duration of incubation or fledging.

Movements. Sedentary.

Status and Conservation. VULNERABLE. CITES II. Restricted-range species: present in South Central American Pacific Slope EBA. Still locally common. Recent decline caused by destruction of mangrove habitat by establishment of salinas and shrimp ponds, road construction and illegal wood cutting. For survival or recovery of remnant populations suitable areas should be protected and existing reserves extended. Generally, still insufficiently protected; for example, the Biological Reserve of Tivives contains only a relatively small amount of *Pelliciera*. Other localities where species occurs include mangroves between the mouths of the rivers Pirris and Palo Seco, Carara Biological Reserve and Golfito Faunal Refuge. Survey of abundance in presumed but still unexplored breeding habitats is necessary to evaluate the current status of the species.

Bibliography. Alfaro (1935), Anon. (1998a), Boucard (1878), Carraker (1910), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Cory (1918), Slud (1964, 1980), Stattersfield *et al.* (1998), Stiles (1985c), Stiles & Skutch (1989), Stotz *et al.* (1996), Wege & Long (1995).

160. Honduran Emerald

Polyerata luciae

French: Ariane de Lucy **German:** Hondurasamazilie **Spanish:** Amazilia Hondureña
Other common names: Honduras/Lucy's Emerald

Taxonomy. *Thaumatias Luciae* Lawrence, 1867, Honduras.

Genus sometimes lumped into *Agyrtia*; these two usually merged into *Amazilia*. Forms a superspecies with *P. boucardi*. Monotypic.

Distribution. Arid interior valleys of N & C Honduras.

Descriptive notes. 9-10 cm. Male has straight, medium-sized bill, upper mandible blackish, lower reddish, distally dusky; upperparts golden green, towards tail-coverts more bronze; throat and breast glittering turquoise to blue-green; flanks greenish, belly with greyish centre; undertail-coverts with white borders and brownish centre; tail slightly forked, light bronze-green, with purplish-black subterminal band on the outer rectrices. Female has throat less intensely turquoise with more greyish areas; grey tips to outer rectrices. Immature resembles female in throat coloration, but has more buff-coloured rectrice tips.

Habitat. Inhabits arid thorn forest, scrub and open woodland, from 75 m to 300 m.

Food and Feeding. Perches and feeds in low to fairly high strata, at 0.5-10 m above ground. Forages for nectar at various flowering plants, such as *Pithecellobium*, *Aechmea*, *Pedilanthus* and Cactaceae. Hunts aerially for insects.

Breeding. Birds in breeding condition observed in June; nesting unknown. Clutch size 2; incubation by female; no data exist on incubation and fledging periods.

Movements. No information available.

Status and Conservation. CRITICALLY ENDANGERED. CITES II. One of the most threatened trochilids. Until its rediscovery in 1988, biology and status were almost unknown, and the taxon was even believed to be extinct. Apparently still locally common; most of recently recorded localities are restricted to upper Aguán Valley; population discovered in Agalta Valley in 1996, where present species was commonest hummingbird, but already threatened by active destruction of habitat for agriculture and grazing. As with *P. boucardi*, the major threat is rapidly increasing habitat destruction; particularly areas with thorn forest have been widely cleared, to be either converted into plantations, especially of pineapples, or used as pasture. Nevertheless, the species seems to tolerate some disturbance, such as grazing, as long as its preferred habitat still survives. Current status of relict populations requires more intensive study, in terms of both population size and range. Conservation measures, chiefly protection of suitable habitats, are urgently required to ensure survival of this species.

Bibliography. Anderson *et al.* (1998), Anon. (1989a, 1998a), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Greenway (1978), Howell & Webb (1989, 1992a, 1995a), Monroe (1968), Moore (1938), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Wege & Long (1995).

Genus SAUCEROTTIA Bonaparte, 1850

161. Steely-vented Hummingbird

Saucerottia saucerrottei

French: Ariane de Sophie **German:** Stahlgrüne Amazilie **Spanish:** Amazilia Verdiazul
Other common names: Saucerotte's/Blue-vented Hummingbird

Taxonomy. *Trochilus saucerrottei* DeLattre and Bourcier, 1846, Cali, Colombia.

Genus usually merged into *Amazilia*. Forms a superspecies with *S. cyanifrons*. Proposed race *australis* described from small series of specimens from Guaitara Valley (SW Colombia) on basis of morphometric differences from nominate; however, strong clinal variation within larger series of nominate birds indicates that it should not be retained. Remarkably isolated race *hoffmanni* sometimes considered to represent a distinct species on basis of behaviour and voice, in addition to distribution; this taxon formerly listed as *S. sophiae*. Four subspecies recognized.

Subspecies and Distribution.

S. s. hoffmanni (Cabanis & Heine, 1860) - W Nicaragua and W & C Costa Rica.

S. s. warszewiczi (Cabanis & Heine, 1860) - N Colombia and extreme NW Venezuela.

S. s. braccata (Heine, 1863) - W Venezuela (Andes of Mérida and Trujillo).

S. s. saucerrottei (DeLattre & Bourcier, 1846) - NW, N & W Colombia.

Descriptive notes. 8-11 cm; male 5.0 g, female 4.5 g. Male has straight, medium-sized bill, upper mandible blackish, lower coral red with dark tip; upperparts golden green; underparts glittering dark golden green; undertail-coverts greenish to steel blue; uppertail-coverts and rectrices blue-black; tail slightly forked. Female similar but differs in white subterminal bars on throat feathers, more greyish-brown undertail-coverts, less forked tail. Immature shows dull green, partially dark grey throat; brownish borders to feathers on back and rump; greyish-brown belly. Race *hoffmanni* has rump and uppertail-coverts coppery to purplish,

rectrices lighter, steel blue; *warszewiczi* has purplish to bluish tinge in uppertail-coverts, smaller in all morphometric characters than all other races; *braccata* often has rump feathers tipped purplish, uppertail-coverts violet-blue to bluish.

Habitat. In general, inhabits open to semi-open, scrubby areas, savannas, forest edges, second growth, plantations, gardens, etc. Normally found in relatively arid habitats, for example N Colombian and Caribbean dry forests, but in dry season also prefers wetter areas like edges of gallery forest. Ranges from sea-level to at most 1500 m; Venezuelan race *braccata* mainly around 2000m, rarely up to 3000 m.

Food and Feeding. Forages at nectar-producing flowers in low bushes and trees, where often becomes territorial. Recorded at great variety of plants, including trees such as *Inga*, *Tabebuia*, or *Genipa*, shrubs like *Hamelia* and *Stachytarpheta*, herbs (*Lobelia*), vines and epiphytes. Feeds also on insects that are sometimes taken from water surface.

Breeding. Almost all year round. In Colombia, birds in breeding condition or nests have been found Jan-Oct; in Costa Rica, Dec-Apr. Small, cup-like nest, made of light-coloured plant down and cobweb, decorated on outside with lichen; built on branch or twig of smaller tree, 2-8 m above ground. Clutch size 2; incubation by female; no further information available.

Movements. Some local dispersal; seasonally abundant in areas with flowering plants.

Status and Conservation. Not globally threatened, CITES II. Fairly common to locally common in more arid regions. Costa Rican population of *hoffmanni* has apparently profited from deforestation and spread of plantations as indicated by recent invasion into the valleys of the central plateau; nevertheless, still uncommon to rare along the Caribbean slope; this race occurs in several protected areas such as Santa Rosa, Palo Verde and Barra Honda National Parks, Costa Rica.

Bibliography. Borrero (1972), Cory (1918), Darlington (1931), Feinsinger (1976, 1977, 1980), Feinsinger & Colwell (1978), Fjeldså & Krabbe (1990), Hellmayr (1913), Hilty & Brown (1986), Meyer de Schauensee (1951), Meyer de Schauensee & Phelps (1978), Miller (1963), Sánchez (1995), Slud (1964, 1980), Stiles (1985b), Stiles & Skutch (1989), Stiles & Wolf (1970), Stotz *et al.* (1996), Tiebout (1989, 1991a, 1991b, 1992, 1993, 1996), Tiebout & Nagy (1991), Trombulak (1983, 1990), Wolf (1970).

162. Indigo-capped Hummingbird

Saucerottia cyanifrons

French: Ariane à front bleu **German:** Blaukappenamazilie **Spanish:** Amazilia Capiazul
Other common names: Blue-capped/Blue-fronted Hummingbird

Taxonomy. *Trochilus cyanifrons* Bourcier, 1843, Ibagué, Colombia.

Genus usually merged into *Amazilia*. Forms a superspecies with *S. saucerrottei*. A certain amount of taxonomic confusion has resulted mainly from occurrence of differing phenotypes. The status of *S. alfarouana* from Volcán de Miravalles (Costa Rica) has been the subject of controversy due to its unusual turquoise blue cap, among other features; since a hybrid origin is most unlikely for phenotypical reasons, more recent opinion suggests that the unique type represents a race of present species; however, other morphological characters, including size, place *alfarouana* close to *S. saucerrottei* as well, so specific status should not be rejected; nevertheless, considering the lack of recent records, *S. alfarouana* should probably be regarded as extinct. A melanistic variety formerly called "Eriocnemis incultus" or "S. nunezi" refers to present species; the specimens concerned have also been erroneously considered aberrant individuals of *S. viridigaster*. Monotypic.

Distribution. N & C Colombia.

Descriptive notes. 7-10 cm; 5.0 g. The only member of the genus that shows a contrasting cap. Male has straight, medium-sized, blackish bill, with basal third of lower mandible fleshy red; crown indigo blue; upperparts shining green with bronze to coppery gloss on rump; underparts glittering golden green; undertail-coverts bordered whitish, coloration of feather centres varying from bronze-green to dark brownish or bluish; uppertail-coverts with bronze or copper tinge, becoming dark blue to bluish-black towards tail; tail slightly forked, rectrices glittering deep steel blue. Female fairly similar but crown more turquoise blue towards the neck;

throat feathers with greyish subterminal bars. Immature resembles female in crown; belly greyer.

Habitat. Edges of subtropical wet forest as well as drier, open habitats with bushes; also found in plantations and gardens. Commonest between 1000 and 2000 m, but down to 400 m in breeding season; rarely up to 3000 m. Post-breeding birds occur occasionally in tropical lowlands at sea-level.

Food and Feeding. Forages for nectar and small arthropods at various heights, but usually in upper strata. Sometimes gathers in some numbers at flowering trees. Recorded feeding plants are trees

and shrubs such as *Eugenia* and *Hamelia* and epiphytes like *Guzmania*; prefers solitary trees. Hunts for insects in the more open canopy region by sallying from perches; rarely gleans arthropods from leaves. Territorial, defending feeding places against other trochilids or nectarivorous species like Bananaquit (*Coereba flaveola*); dominance over *Agyrtia franciae* has been observed.

Breeding. Data on gonadal activity indicate season probably Apr-Jul; nest-building also recorded until Aug. Nest resembles that of congeners; cup-like, made of moss, lichens and cobweb. Clutch size 2; incubation by female; no data exist on duration of incubation or fledging.

Movements. Occasional occurrence in the Pacific lowlands suggests altitudinal migration tied to seasonal availability of food plants.

Status and Conservation. Not globally threatened, CITES II. Generally uncommon to locally common resident of semi-open woodland. Status not well known, but wide altitudinal range, combined with apparent adaptability to man-made habitats, suggests species relatively secure at present.

Bibliography. Berlioz (1937), Cory (1918), Elliot (1889), Furness (1979), Greenway (1978), Hilty & Brown (1986), Meyer de Schauensee (1982), Munves (1975), Olrog (1968), Schuchmann (1979e), Slud (1964), Snow & Snow (1980), Stiles & Skutch (1989), Stotz *et al.* (1996), Underwood (1896).

163. Snowy-breasted Hummingbird

Saucerottia edward

French: Ariane d'Edward **German:** Edwardamazilie **Spanish:** Amazilia de Edward
Other common names: White-bellied(ly)/Snowy-bellied Hummingbird (*niveoverter*); Edward's Hummingbird (*edward*)

Taxonomy. *Trochilus edward* DeLattre and Bourcier, 1846, Isthmus of Panama.

Genus usually merged into *Amazilia*. Race *niveoverter* has been considered a distinct species, based mainly on tail coloration and, in this character, lack of intergradation with other races due to strictly allopatric distribution. Individuals with intermediate characters of races *edward* and *margaritarum* have been reported from contact zone in E Panama. Two questionable races were described from the mainland of Panama: the form *croshyi* of Darién (E Panama) was separated by tail coloration from race *margaritarum*, but is indistinguishable from it, as the characters of most individuals of the type series can be accounted for by juvenile plumage; *ludibunda*, described from a single specimen from Pesé in Azuero Peninsula (C Panama), was collected within the eastern range of *niveoverter* and represents an aberrant example of this race. Four subspecies recognized.

Subspecies and Distribution.

S. e. niveoverter (Gould, 1851) - SW Costa Rica to W & C Panama, including Coiba I.

S. e. edward (DeLattre & Bourcier, 1846) - Panama, from Canal Zone to W Darién.

S. e. collata (Wetmore, 1952) - C Panama.

S. e. margaritarum Griscom, 1927 - N Gulf of Panama, in Pearl Is and on Urabá I, Taboga I and Taboguilla I; E Panama to SW Darién.

Doubtfully recorded in Ecuador (Santo Domingo), perhaps race *margaritarum*.

Descriptive notes. 8-11 cm; male 5.0 g, female 4.4 g. Blackish, straight bill, with reddish base to lower mandible. Male has upperparts bronze-green to coppery, especially on back and rump; throat and chest glittering golden green, belly with V-shaped white centre; undertail-coverts rufous, rectrices bronze to coppery, sometimes with purple sheen. Female similar but normally has less intense coloration on upperparts; more whitish on throat and in undertail-coverts; light green tips on outer rectrices. Immature has greyish-brown sides instead of the pure white belly of adults. Race *niveoverter* slightly larger, with tail blue-

ish-black to purplish-black; *collata* has less contrasted back, brownish undertail-coverts; *margaritarum* can be differentiated by paler undertail-coverts and bronze to bronze-green tail.

Habitat. Varies with distribution; in Costa Rica and the western parts of Panama prefers semi-open habitats and savannas with scrub and scattered trees, open woodland, clearings, forest edges, second growth, coffee plantations, flowery thickets, gardens and roadsides. Race *niveoverter* has widest altitudinal tolerance, from near sea-level to 1600 m in Chiriquí, W Panama. Race *collata* is found around El Valle in areas with low, woody-stemmed herbs as well as abandoned fields with low bushes at 500-850 m. Race *margaritarum* shows disjunct range; island populations occur in semi-open to open habitats, abandoned fields, mangrove swamps, and along small streams; mainland population also inhabits rainforest, between sea-level and 700 m.

Food and Feeding. Forages and perches at varying heights, mainly between 3 and 6 m. Usually solitary, but may gather in numbers at flowering trees. Food plants include tree species (*Inga*, *Calliandra*, *Vochysia*, *Quassia*), shrubs (*Palicourea*, *Stachytarpheta*) and a variety of introduced plants. Sometimes feeding territories are defended, even against larger trochilids like *Florisuga mellivora* which can be vigorously pursued. Arthropod diet includes small spiders, flies (Diptera) and Hymenoptera, caught by hawking, often over water, or gleaned from leaves.

Breeding. For western populations, breeding has been recorded between Oct and Jan, with peak Dec-Jan during onset of dry season. Nest is placed on horizontal branch beside vertical stem, or in fork, 1.5-9 m above ground; compact, downy cup of brown fibres, covered on outside with red and green lichens and sometimes green moss. Favourite nesting spots are bushes and smaller trees, often in open areas such as fields or roadsides. Clutch size 2; incubation by female; no information on incubation and fledging periods.

Movements. Western populations at least show local movements. Probably remains in more arid areas during wet season, retreating to the headwaters of rivers during dry season. In Buena Vista Valley, Costa Rica, disappearance of race *niveoverter* correlated with absence of flowering from Feb-Mar to Apr-May; individuals of that race may also migrate along the Atlantic coast as indicated by specimen records from Bocas del Toro, NW Panama.

Status and Conservation. Not globally threatened, CITES II. One of the commonest trochilids in the Canal Zone of Panama; locally common in SW Costa Rica and W Panama in the upper tropical to subtropical zone. Race *collata*, although more restricted in altitude and range than the other races, apparently abundant in open, shrubby habitat; *margaritarum* is relatively common resident in Pearl Is and adjacent islands; within mainland range, becomes uncommon in NW Darién and eastern parts of Panama such as Chucanti and Ultima.

Bibliography. Anon. (1998a), Blake (1958), Carraker (1910), Cory (1918), Deignan (1961), Hartman (1957), Oberholser (1902), Olson (1997), Ridgely & Gwynne (1989), Roubik *et al.* (1985), Skutch (1961a, 1972), Slud (1964), Stiles (1985c), Stiles & Skutch (1989), Stone (1918), Stotz *et al.* (1996), Todd (1942), Wetmore (1946, 1952, 1957a, 1968a), Willis & Eisenmann (1979).

164. Blue-tailed Hummingbird

Saucerottia cyanura

French: Ariane à queue bleue German: Blauschwanzamazilie Spanish: Amazilia Coliazul

Taxonomy. *Amazilia cyanura* Gould, 1859, Realejo, Nicaragua.

Genus usually merged into *Amazilia*. Forms a superspecies with *S. beryllina*; reports of hybridization in a small zone of sympatry in Guatemala and El Salvador seem to be unproven, and may be erroneously based on variable tail coloration of that species. In recent literature only two races have been recognized, with *impatiens* from Costa Rica ignored, perhaps because only two specimens exist; however, morphological characters indicate that it should be considered valid. Races show highly disjunct distribution. Three subspecies recognized.

Subspecies and Distribution.*S. c. guatemalae* Dearborn, 1907 - SE Mexico (SE Chiapas) to S Guatemala.*S. c. cyanura* (Gould, 1859) - S Honduras, E El Salvador and NW Nicaragua.*S. c. impatiens* Bangs, 1906 - NW & C Costa Rica.

Descriptive notes. 9-10 cm; 4.0 g. Male has straight, medium-sized, blackish bill, except for reddish base of lower mandible; crown, nape and back golden to bronze-green; rump with copper to purplish reflections; base of outer secondaries and inner primaries broadly rufous; underparts glittering golden green; uppertail-coverts purple-violet to deep blue, rectrices deep blue, undertail-coverts bluish with grey to rufous edges. Female similar but has reduced wing patch; more greyish areas on throat and belly; edges of undertail-coverts broader greyish. Immature has dull green throat feathers, more greyish to rufous belly and margins of undertail-coverts. Race *guatemalae* shows more copper to purplish back and rump, rufous in wings less extensive; *impatiens* has extended rufous in wings, undertail-coverts broader and darker, edged with rufous.

Habitat. Found in humid and arid forests with pine or oak, second growth, clearings, semi-open to open areas with scrub; also in man-made habitats such as coffee plantations. In Honduras, inhabits arid areas on Pacific slope but also more humid deciduous forest habitats on Caribbean side. Mainly below 1000 m; nominate *cyanura* has altitudinal distribution from near sea-level to 1200 m; *guatemalae* from 150 to 1800 m. Recent localities of race *impatiens* indicate primary forest as original habitat at 500-1000 m.

Food and Feeding. Forages for nectar at various heights; often seen at flowering *Inga* trees. Hawks for insects in the air.

Breeding. No information available.

Movements. Chiefly sedentary, although altitudinal distribution may vary with season.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species; present in North Central American Pacific Slope EBA. Status differs over range. Generally, common in the Pacific lowlands but uncommon on the Caribbean slope of Honduras. Race *guatemalae* locally abundant in SE Mexico and SW Guatemala. Current status of race *impatiens* in Costa Rica unknown; not recorded since 1958, and may be at least close to extinction; the only records, all from this century, amount to two specimens, as well as one possible sighting, although the individuals concerned have often been regarded as northern vagrants; remnant populations, if they still exist, would most likely be found in relatively undisturbed, shrubby woodland habitats within the NW part of the volcanic belt.

Bibliography. Anon. (1998a), Dearborn (1907), Dickey & van Rossem (1938), Friedmann *et al.* (1950), Howell & Webb (1995a), Land (1970), Monroe (1968), Rand & Traylor (1954), Slud (1960, 1964), Stattersfield *et al.* (1998), Stiles (1980), Stiles & Skutch (1989), Stotz *et al.* (1996), Thurber *et al.* (1987), Warren (1966).

165. Berylline Hummingbird

Saucerottia beryllina

French: Ariane beryl German: Beryllamazilie Spanish: Amazilia Berilina

Taxonomy. *Trochilus beryllinus* Lichtenstein, 1830, Mexico.

Genus usually merged into *Amazilia*. Forms a superspecies with *S. cyanura*; reports of hybridization in a small zone of sympatry in Guatemala and El Salvador seem to be unproven, and may be erroneously based on variable tail coloration of present species. Race *sumichrasti*, long ignored, has proved to represent a well-marked race. Individuals of westernmost subpopulation of nominate race show intergradation towards *viola* in belly coloration. Proposed race *motaguae* from E Guatemala is invalid, as main distinguishing characters can be ascribed to juvenile or female plumage. Five subspecies recognized.

Subspecies and Distribution.*S. b. viola* (W. deW. Miller, 1905) - NW & W Mexico, rarely SW USA.*S. b. beryllina* (Lichtenstein, 1830) - C Mexico.*S. b. lichtensteini* R. T. Moore, 1950 - S Mexico (W Chiapas).*S. b. sumichrasti* (Salvin, 1891) - S Mexico (C & S Chiapas).*S. b. devillei* (Bourcier & Mulsant, 1848) - S Guatemala and El Salvador to C Honduras.

Descriptive notes. 8-10 cm; male 4-4 g, female 4-0 g. Male has straight, medium-sized, blackish bill, except for fleshy-coloured basal half of lower mandible; bronze-green to coppery on head, back and rump; base of primaries and secondaries chestnut; underparts glittering golden green; uppertail-coverts and tail variable, often coppery to rufous. Female similar but has throat and belly paler, more greyish. Immature is similar to female but with less iridescence on throat; belly greyish-cinnamon. Race *viola* has greyish tinge on back and rump, belly fawn to cinnamon, uppertail-coverts and rectrices dark violet-blue; *lichtensteini* is generally lighter green, wing band paler, rectrices silvery-coloured; *sumichrasti* has somewhat purplish gloss to tail. Female with silvery to purple inner rectrices; *devillei* shows stronger bronze to coppery on back and rump, wing band paler, tail purplish to bronzy-chestnut.

Habitat. Inhabits edges of tropical lowland or sub-montane evergreen forest, second growth, clearings, scrub and plantations. Found from foothills to highlands, from 200 m to 2100 m, but chiefly between 400 and 1700 m.

Food and Feeding. Feeds for nectar throughout foliage strata, often congregating with other hummingbird species at flowering trees; catches small insects at spider webs or by hawking. Depending on habitat, feeds on both native and introduced plants, including *Malvaviscus*, *Psittacanthus* and *Calliandra*, also succulents like *Ceiba* and *Lemnaireocereus*. Generalist forager, often occupying feeding territories. On the whole relatively dominant although subdominance was registered where sympatric with *Lampornis amethystinus*.

Breeding. Chiefly Jun-Oct, in Oaxaca with peak in Sept. Nest-sites from low down to 15 m above ground in shrubs and trees such as *Wigandia*, pine and oak, in Arizona also in sycamore (*Platanus*). Nest rather solid, on horizontal branch, made of grass, plant fibres, cotton, and often with a conspicuous streak of grass blades near the bottom that are fixed with cobweb; outside decorated with light-coloured lichens; measures 40-50 mm both in outside diameter and depth, inside depth of c. 15 mm and width of c. 26 mm. Clutch size 2; incubation by female; fledging at about 20 days.

Movements. Sedentary in many parts of the range, except for the extreme north where regular migrant, mainly southward. Occasionally occurs as wanderer or rare breeder in southern Arizona, USA, where records date from mid-Jun to late Sept. Some altitudinal movements observed where birds occur at lower elevations after breeding.

Status and Conservation. Not globally threatened. CITES II. Very local and rare in SW USA, where apparently confined to Huachuca Mts and Chiricahua Mts of Arizona. Few records exist for the E slope of northern Sierra Madre Occidental, with southward distribution at least as far as Barranca del Cobre National Park. Common resident along the Pacific slope and interior highlands from NW Mexico to Guatemala. Uncommon in arid Motagua Valley of NE Guatemala; less common along Atlantic slope from Mexico to C Honduras. Race *lichtensteini* has most restricted range, confined to Cerro Brujo, W Chiapas (Mexico).

Bibliography. Anderson & Monson (1981), Baicich & Harrison (1997), Berlioz (1932b), Binford (1989), Carraker & Meyer de Schauensee (1935), Davis (1953), Des Granges (1979), Des Granges & Grant (1980), Friedmann *et al.* (1950), Hartert & Hartert (1894), Hejl *et al.* (1995), Hernández & Toledo (1980), Howell & Webb (1995a), Johnsgard (1997), Kaufman (1996), Land (1962, 1970), Lasley & Sexton (1992), Lowery & Dalquest (1951), Martínez del Río & Eguiarte (1987), Monroe (1968), Moore (1950b), Ridgway (1911), van Rossem (1945a), Rowley (1962, 1966, 1984), Schaldach (1963), Sheppard (1968), Sitzeman *et al.* (1976), Stager (1954), Stotz *et al.* (1996), Sutton (1952), Tashian (1953), Wagner (1957b), Webster (1959), Weller (1998), Williams (1993), Zimmerman & Harry (1951).

166. Green-bellied Hummingbird

Saucerottia viridigaster

French: Ariane à ventre vert German: Grünbauchamazilie Spanish: Amazilia Colimorada

Taxonomy. *Trochilus viridigaster* Bourcier, 1843, Fusagasuga, Colombia.

Genus usually merged into *Amazilia*. Forms a superspecies with *S. cupreicauda* and *S. tobaci*; normally considered conspecific with former, but morphological differences, in addition to highly disjunct ranges, support their separation as two distinct species. Race *iodura* has generally been overlooked or rejected in recent literature; however, on the basis of morphology, in combination with distribution, it appears to be a valid race; intergradation of the two races may occur south of Táchira depression. Proposed race *melanura* is now regarded as an aberrant form of nominate race. Two subspecies recognized.

Subspecies and Distribution.*S. v. viridigaster* (Bourcier, 1843) - E slope of E Andes of Colombia (S to Sierra Macarena); doubtfully W slope as indicated by the type locality.*S. v. iodura* Reichenbach, 1854 - Andes of Táchira (W Venezuela).

Descriptive notes. 8-9 cm; 4-5 g. Male has straight, medium-sized bill; upper mandible black, lower mostly pinkish with dark tip; head and back golden green; rump and tail-coverts olive green to buff or brownish; uppertail-coverts sometimes with purplish tinge; underparts darker shining green; tail slightly forked, deep blue to violet-blue. Female similar but has throat feathers fringed white; rectrices edged with bronze to brownish. Immature has more brown on rump; belly greyish-brown. Race *iodura* has tail relatively unicoloured coppery to purple in both sexes.

Habitat. Inhabits edges of tropical lowland or sub-montane evergreen forest, second growth, clearings, scrub and plantations. Found from foothills to highlands, from 200 m to 2100 m, but chiefly between 400 and 1700 m.

Food and Feeding. Forages for nectar and small insects in understorey and middle strata. Assembles at flowering trees like *Erythrina*.

Breeding. Poorly known. Birds in breeding condition were found in Oct, Dec, Jan. Clutch size 2; incubation by female; no data exist on duration of incubation or fledging.

Movements. No information available; probably performs some local movements.

Status and Conservation. Not globally threatened. CITES II. Fairly common to uncommon resident of the sub-montane tropical zone of E slope of Andes in Colombia, where occurs southwards at least as far as Macarena Mts. In Venezuela, only recorded in Andes of Táchira, but northern distributional limits require confirmation.

Bibliography. Berlioz (1933a), Blake (1962), Chapman (1917, 1931), Hilty & Brown (1986), Meyer de Schauensee (1949, 1964, 1982), Meyer de Schauensee & Phelps (1978), Nicéforo (1940), Olivares (1963), Olrog (1968), Sánchez (1995), Simon (1921), Stotz *et al.* (1996), Todd (1942).

167. Copper-tailed Hummingbird

Saucerottia cupreicauda

French: Ariane à queue cuivrée German: Kupferschwanzamazilie Spanish: Amazilia Colicobrizza

Taxonomy. *Amazilia cupreicauda* Salvin and Godman, 1884, Mount Roraima, Guyana.

Genus usually merged into *Amazilia*. Forms a superspecies with *S. viridigaster* and *S. tobaci*; normally considered conspecific with former, but morphological differences, especially in coloration

of rump, uppertail-coverts and rectrices, in addition to disjunct ranges, support their separation as two distinct species. Three subspecies recognized.

Subspecies and Distribution.

S. c. cupreicauda (Salvin & Godman, 1884) - highlands and *tepui*s of E Venezuela, Guyana and extreme N Brazil (Roraima).

S. c. duidae Chapman, 1929 - S Venezuela.

S. c. laireti (Phelps, Jr. & Aveledo, 1988) - extreme S Venezuela; possibly N Brazil.

Descriptive notes. 9-10 cm; male 3-9 g, female 3-5 g. Male has straight, medium-sized bill, upper mandible blackish, lower fleshy red with dark tip; crown golden green, nape, back and rump golden green to bronze or coppery, the latter sometimes with purplish reflections; underparts glittering golden green; tail-coverts, base and centre of tail feathers rufous to chestnut; rectrices more or less bicoloured, broadly edged bronze to purple. Female similar but has more prominent white bases to chin feathers; back and tail often less contrasted. Immature has dark grey lower belly to abdomen. Race *duidae* has more coppery lower back and rump,

rectrices bronze to purplish, basally lacking rufous; *laireti* is slightly darker green, with uppertail-coverts and rectrices uniformly golden bronze to copper.

Habitat. Mainly found along forest edges, in clearings and scrub. Ranges from foothills to highlands, inhabiting slopes as well as tops of *tepui*s. Nominant race mostly found between 500 and 1300 m, rarely below though once recorded at 85 m in Kanuku Mts, Guyana. Race *duidae* is a bird of primary forest edges, with an upper altitudinal limit of c. 1400 m. By contrast, *laireti* prefers open to semi-open shrubland with vegetation dominated by bromeliads and terrestrial orchids, mainly in the subtropical zone between 750 and 1850 m.

Food and Feeding. Poorly known; diet includes nectar as well as small insects and spiders. Race *laireti* recorded feeding on epiphytes.

Breeding. Season not well known but at least Jan-May. One nest, found in Feb in Kanuku Mts, contained two nestlings: it was situated in a small tree, 3 m above ground, placed at the end of a branch and fixed between twigs with cobweb; outside was covered with moss, lichens, cobweb, inside lined with thick, tawny plant down. Clutch size 2; incubation by female; no data exist on incubation and fledging periods.

Movements. Chiefly sedentary; seasonal altitudinal movements may occur.

Status and Conservation. Not globally threatened. CITES II. Fairly common to uncommon, but different populations isolated. Distribution of race *cupreicauda* apparently concentrated in La Gran Sabana region and Mt Roraima National Park, along the Venezuelan-Guyanese border. Race *duidae* most common in Duida-Marahuaca National Park. Southernmost race *laireti* has been recorded from only two localities but seems to be locally abundant in Serranía de la Neblina National Park. Presumably, current extent of distribution of the southern races exceeds known ranges due to collecting gaps in the SE highlands of Venezuela and adjacent areas such as Roraima, Brazil.

Bibliography. Barrowclough *et al.* (1995), Berlioz (1933a), Chapman (1929, 1931), Chubb (1916), Cory (1918), Forrester (1993), Grantsau (1988), Haverschmidt & Mees (1994), Mayr & Phelps (1967), Meyer de Schauensee (1982), Meyer de Schauensee & Phelps (1978), Novas (1965), Phelps (1972), Phelps & Aveledo (1988), Ruschi (1981-1982, 1986), Sánchez (1995), Sick (1993, 1997), Snow & Snow (1974), Snyder (1966), Willard *et al.* (1991).

168. Copper-rumped Hummingbird

Saucerottia tobaci

French: Ariane de Félicie **German:** Kupferbüzelamazilie **Spanish:** Amazilia de Tobago
Other common names: Common Emerald

Taxonomy. *Trochilus Tobaci* J. F. Gmelin, 1788, Tobago.

Genus usually merged into *Amazilia*. Forms a superspecies with *S. viridigaster* and *S. cupreicauda*. Proposed race *apurensis* most probably falls within individual variation of race *feliciae*. A specimen said to have been taken on Grenada, and described as "*S. wellsii*", has alternatively been

treated as a vagrant of nominate race; however, its true origin appears dubious. Seven subspecies recognized.

Subspecies and Distribution.

S. t. tobaci (J. F. Gmelin, 1788) - Tobago.

S. t. erythronotos (Lesson, 1829) - Trinidad.

S. t. aliciae (Richmond, 1895) - I Margarita, Venezuela.

S. t. monticola Todd, 1913 - NW Venezuela.

S. t. feliciae (Lesson, 1840) - NC Venezuela.

S. t. caudata (Zimmer & Phelps, 1949) - NE Venezuela.

S. t. caurensis Berlepsch & Hartert, 1902 - E & SE Venezuela.

Descriptive notes. 9-11 cm; male 4-6 g, female 4-2 g. Male has straight, medium-sized, blackish bill, except for pinkish base of lower mandible; upperparts bronze-green; underparts glittering dark golden green; uppertail-coverts purple-red; undertail-coverts reddish-brown; rectrices purplish-black. Female similar but coloration of back normally less intense; whitish on chin and upper throat. Immature has throat and belly partially greyish-brown. Other races differ morphometrically from nominate, which is by far the largest; *erythronotos* slightly darker below, with centres of uppertail-coverts dark purplish; *monticola* is generally darker,

less contrasted, with rectrices steel-blue to violet-blue, undertail-coverts reddish-brown; *feliciae* has back more glittering golden to bronze-green, tail bluish-black, undertail-coverts reddish-brown; *caudata* has tail dark blue, *aliciae* has more copper in upperparts and tail blue-black, both with undertail-coverts cinnamon-rufous; *caurensis* is greyer on rump and uppertail-coverts, tail less bifurcated, dark purplish, undertail-coverts bluish black.

Habitat. Inhabits nearly all types of forest, including gallery forest, cloudforest and rainforest, and also second growth and clearings; island races *erythronotos* and *tobaci* also occur in open country with savanna-like vegetation, plantations and gardens. Ranges mainly between sea-level and 1000 m; some mainland races like *monticola* and *feliciae* reach 1500-2000 m. In contrast to other island races, *aliciae* of Margarita I seems to prefer mountainous areas.

Food and Feeding. Feeds mainly on nectar of a great variety of plants; more than 40 species of trees, particularly *Erythrina* and *Calliandra*, shrubs (*Palicourea*), vines (*Gurania*), herbs (*Pachystachys*) and various introduced plants (*Hibiscus*, *Russelia*) were recorded for Trinidad and Tobago. Forages for insects in vegetation, or hawks over fallen fruits for small flies. Extremely territorial; dominates other hummingbirds, even larger species. Attacks any intruders within the feeding area, either directly or sometimes in pendulum-like flight if intruder perched. Insects are caught in the air by hawking.

Breeding. Poorly known in mainland races. On Trinidad, breeding recorded from all months except Sept-Oct, with main season Jan-Mar. On Tobago, nesting noted Nov-Jun. Saddle-type nest, usually placed in fork or on branch of small tree or bush, 1-3 m above ground, sometimes up to 6 m; nests occasionally found on wires, clothes-lines(!), etc. Cup is made of silky plant down, sometimes with coconut fibres or scales of fern fronds, decorated with pieces of lichen and cobweb. Clutch size 2; incubation 16-19 days, by female; fledging period 19-23 days. 2-3 broods per season, at intervals of 1 week to 1 month.

Movements. Insular races generally sedentary, though claimed record from Grenada could refer to a vagrant; some birds of mainland races perform local movements.

Status and Conservation. Not globally threatened. CITES II. Common to very common on the islands of Trinidad and Tobago, where frequently found even in urban areas. Race *feliciae* represents the commonest of the mainland races, occurring in city parks in Caracas, etc. Race *caudata* also common, frequently occurring in gardens and other man-made habitats. Distribution of other Venezuelan races, *caurensis* for example, appears more scattered, possibly due in part to a lack of collecting sites.

Bibliography. Allen (1961), Anon. (1985a), Barrowclough *et al.* (1997), Belcher & Smooker (1936), Berlioz (1933a), Clark, A.H. (1902), Dinsmore & French (1969), Feinsinger (1980), Feinsinger & Swann (1982), French (1991), Friedmann (1948), Friedmann & Smith (1950), Gilliard (1941), Hayes & Samad (1998), Herklots (1961), Jouanin (1946), Junge & Mees (1961), Meyer de Schauensee & Phelps (1978), Muir & Butler (1925a), Rieckels (1968), Sánchez (1995), Stotz *et al.* (1996), Thomas (1993), Todd (1942), Wetmore (1939), Zimmer & Phelps (1949).

inches 2
cm 5

Genus *MICROCHERA* Gould, 1858

169. Snowcap

Microchera albocoronata

French: Colibri à coiffe blanche **German:** Schneekappenkolibri **Spanish:** Colibri Coroniblanco
Other common names: White-crowned Hummingbird

Taxonomy. *Mellisuga albo-coronata* Lawrence, 1855, Belén, Veraguas, Panama.

Two subspecies recognized.

Subspecies and Distribution.

M. a. parvirostris (Lawrence, 1865) - Caribbean slope of S Honduras, Nicaragua, Costa Rica and probably extreme W Panama.

M. a. albocoronata (Lawrence, 1855) - both slopes of WC Panama.

Descriptive notes. 6-6.5 cm; male 2.5 g, female 2-6 g. Bill and feet black. Male has entire crown glistening white, throat glossed green, rest of head and underparts purplish-black; remainder of upperparts metallic reddish-purple, passing to metallic bronze on central rectrices, lateral rectrices with basal half or more white, rather sharply set off from black terminal band. Female metallic green above, greyish-white below, uppertail-coverts and central rectrices bronze; lateral rectrices with basal half or more white, rather sharply set off from black subterminal band. Immature of both sexes resembles adult female but greyer below, with greyish-buff to rusty feather fringes over much of upperparts; lower upperparts of young male more bronzy, less purplish; purple feathers on underparts of young male first appear along mid-line, producing striking dark medial stripe. In race *parvirostris*, male is reddish-purple above and below, generally brighter than nominate; throat dusky brown, underparts bright reddish-purple; in both sexes the lateral rectrices are extensively clouded with dusky grey proximal to the dark band.

Habitat. Wet forest, forest edges, adjacent semi-open and second growth in foothills and lowlands; male more in subcanopy and canopy, coming down lower along edges and in second growth; female frequents understorey and middle strata in forest, often higher in semi-open habitat. In Costa Rica, breeds at 300-800 m, rarely 1000 m; after breeding descends to lowlands; occurs at 600-1650 m in Panama.

Food and Feeding. Visits mostly small flowers of trees (*Warscewiczia*, *Sickingia*, *Inga*, *Pithecellobium*), shrubs (*Sabicea*, *Besleria*, *Hamelia*, *Cephaelis*, *Psychotria*), vines (*Gurania*) and epiphytes (*Columnea*, *Norantea*, *Cavendishia*) in forest, often frequenting hedges of *Stachytarpheta* in adjacent gardens. Male may defend feeding territories against other conspecifics but is displaced by most other species. Gleans insects and spiders from foliage; male often sallies for flies and gnats.

Breeding. Dry to early wet seasons (Jan-May) in Costa Rica. During breeding season male sings a soft, sputtering warble from exposed twigs 4-8 m up at forest edge, usually in small leks of 3-6. Nest a tiny cup of treefern scales, plant down and cobweb, lightly decorated with green moss and with a few bits of lichen around the rim, 1-5.3 m up on lower twig of tree, or vine hanging from tree. No further information.

Movements. Descends to lowlands (regularly to 50-100 m, occasionally to sea-level) following breeding.

Status and Conservation. Not globally threatened. CITES II. While deforestation is severe in many parts of range in Costa Rica, species remains locally common in others, such as the lower part of Braulio Carrillo National Park and Rara Avis Reserve, although its preferred foothill elevations are below the limits of most protected areas.

Bibliography. Anon. (1998a), Carriker (1910), Fogden (1993), Howell, S.N.G. & Webb (1995a), Howell, T.R. (1957), Marin & Schmitt (1991), Monroe (1968), Ridgely & Gwynne (1989), Ridgway (1911), Slud (1964), Stiles (1980, 1985b, 1985c), Stiles & Clark (1989), Stiles & Skutch (1989), Stotz *et al.* (1996), Wetmore (1968a).

Genus *ANTHOCEPHALA* Cabanis & Heine, 1860

170. Blossomcrown

Anthocephala floriceps

French: Colibri à tête rose **German:** Blaustrirnkolibri **Spanish:** Colibrí Florido

Taxonomy. *Trochilus* (—?) *floriceps* Gould, 1854, Sierra de Santa Marta, Colombia.

Systematic relationships uncertain; perhaps closely related to *Microchera*; sometimes alternatively considered close to *Adelomyia*, and possibly even congeneric. Two subspecies recognized.

Subspecies and Distribution.

A. f. floriceps (Gould, 1854) - Santa Marta Mts (NE Colombia).

A. f. berlepschi Salvin, 1893 - Magdalena Valley, on E slope of C Andes (C Colombia).

Descriptive notes. c. 8-4 cm. Male has straight, black bill; forecrown buffy white, hindcrown rufous chestnut, rest of upperparts shining green, postocular spot white; underparts greyish-buff, tail squared, bronzy-green, tipped pale buffy, black subterminal bar, lacking on central pair of rectrices. Female similar to male, crown brownish. Immature resembles adult female. Race *berlepschi* differs in having largely white tips to tail.

Habitat. Humid forest and older second growth. Generally found at 1200-2300 m; in Santa Marta, normally at 600-1700 m, but one nesting record at 2400 m.

Food and Feeding. No specific food plants have been recorded, except for flowering banana. Usually forages at low levels in understorey.

Breeding. Birds in breeding condition Sept-Oct, Santa Marta. No further information available.

Movements. Sedentary.

Status and Conservation. Not globally threatened. CITES II. Currently considered Near-threatened. Restricted-range species: present in Santa Marta Mountains EBA and Colombian Inter-Andean Slopes EBA. Generally rare, but locally abundant in parts of Santa Marta. In conjunction with small range, species may be

vulnerable to habitat destruction; not known to accept man-made habitats.

Bibliography. Fjeldså & Krabbe (1990), Hilty (1985), Hilty & Brown (1986), Meyer de Schauensee (1982), Olrog (1968), Renjifo *et al.* (1997), Ridgely & Gaulin (1980), Salaman & Mazariegos (1998a), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Todd & Carriker (1922).

Genus *CHALYBURA* Reichenbach, 1854

171. White-vented Plumeleteer

Chalybura buffonii

French: Colibri de Buffon **German:** Blauschwanz-Buffonkolibri **Spanish:** Colibrí de Buffon
Other common names: Buffon's Hummingbird; Blue-bellied Plumeleteer (*caeruleogaster*)

Taxonomy. *Trochilus Buffonii* Lesson, 1832, Brazil; error = Bogotá region, Colombia.

Type specimen has sometimes been ascribed to populations from Panama and W Colombia, with consequent reshuffling of subspecific nomenclature; under that arrangement, birds currently listed as nominate become race *interior*, whereas those of current race *micans* become nominate. Another variation occasionally adopted, under present arrangement with type locality of Bogotá region, involves population around L Maracaibo basin being split as a separate race, for which name *interior* is likewise available; however, these differences are slight, and subspecific separation of Maracaibo birds unjustified. In past, race *caeruleogaster* often considered a separate species. Race *intermedia* of *C. urochrysis*, from SW Ecuador, sometimes ascribed to present species, but its largely pinkish mandible supports treatment in that species; nevertheless, it might be better considered a separate species; more study required. Four subspecies recognized.

Subspecies and Distribution.

C. b. micans Bangs & Barbour, 1922 - C & E Panama and W Colombia (Pacific slope, Cauca Valley and head of Magdalena Valley).

C. b. buffonii (Lesson, 1832) - C Colombia (upper and middle Magdalena Valley) to S & W parts of L Maracaibo basin and adjacent slopes in extreme NE Colombia and NW Venezuela.

C. b. aeneicauda Lawrence, 1865 - N Colombia (lower Magdalena Valley and Santa Marta region) to W & NC Venezuela (along S slope of Andes and on coastal slope).

C. b. caeruleogaster (Gould, 1847) - N & C Colombia (E slope of E Andes).

Descriptive notes. 10-5-12 cm; male 6-9-7.3 g, female 5-9-6.2 g. Bill always completely black, feet black. Male of nominate dark metallic green above, crown and hindneck more bronzy, uppertail-coverts more coppery-bronze; below bright metallic green, bluish on upper breast, lower belly whitish, undertail-coverts elongated, fluffy, white; tail blue-black, the central rectrices glossed bronzy. Female is grey below, rather heavily speckled with green laterally and sometimes across chest, lateral rectrices tipped dull grey. Immature male duller green below; both sexes with some buffy fringes on crown, nape and rump feathers. Race

micans larger, central rectrices deeper blue, female clearer grey below; male of *aeneicauda* often more golden green below, central rectrices bright bronze-green to copper-bronze. Female pale grey below with sparse green flecking; race *caeruleogaster* larger, male with throat and belly bluish-green, breast blue, female clear grey below, immature male with little or no blue below.

Habitat. Dry, moist and wet forests, forest edges, semi-open and second growth; in wetter areas where sympatric with *C. urochrysis* prefers more open, scrubby places rather than forest; only *caeruleogaster* and to a lesser extent *buffonii* occur regularly inside wet forest. Found from sea-level locally to 2000 m.

Food and Feeding. Takes nectar from flowers of a variety of trees (*Inga*, *Calliandra*, *Trichanthera*, *Erythrina*), shrubs (*Aphelandra*, *Malvaviscus*, *Hibiscus*, *Hamelia*, *Palicourea*) and large herbs (*Heliconia*); very aggressive and dominant at flowers, supplanting other hummingbirds in aggregations at flowering trees, male often territorial at rich patches of flowers; may pierce flowers with long corollas. Frequently flycatches, sallies from perch or during prolonged bouts of hovering and darting, usually in open or along edges; also sometimes gleans arthropods from foliage or spiders' webs.

Breeding. Mar-Jul or Aug (*buffonii*, Magdalena Valley); Jun-Nov (*caeruleogaster*). Nest is a neat cup of plant down and cobweb, decorated with pieces of lichen and bits of moss; one nest of *caeruleogaster* 2.5 m above ground in guava tree in garden adjoining forest. No further information.

Movements. No information available.

Status and Conservation. Not globally threatened. CITES II. Uncommon to fairly common in most areas, and seems able to tolerate considerable disturbance, taking advantage of forest clearance in wetter areas over most of range. Only race *caeruleogaster* seems likely to have declined, due to deforestation of lower Andean slopes and adjacent lowlands over much of range, though it

remains at least locally common in some areas. In Venezuela, species occurs in several protected areas such as Cueva del Guácharo and Henri Pittier National Parks.

Bibliography. Anon. (1998a), Hilty & Brown (1986), Meyer de Schauensee & Phelps (1978), Olrog (1968), Parker *et al.* (1995), Phelps & Phelps (1958), Ridgely & Gwynne (1989), Stotz *et al.* (1996), Todd (1942), Wetmore (1968a), Wiedenfeld *et al.* (1985), Willis & Eisenmann (1979).

172. Bronze-tailed Plumeleteer

Chalybura urochrysis

French: Colibri à queue bronzée

Spanish: Colibrí Pátrirjo

German: Bronzeschwanz-Buffonkolibri

Other common names: Red-footed Plumeleteer; Black-vented/Dusky Plumeleteer (*melanorrhoea*); Ecuadorian Plumeleteer (*intermedia*)

Taxonomy. *Hypoprottila urochrysis* Gould, 1861, western Colombia.

Race *melanorrhoea* long considered a separate species, but intergrades with *isaurae* along border of Costa Rica with Panama. Geographically isolated race *intermedia* often placed in *C. buffoni*, but its largely pinkish mandible supports treatment in present species; nevertheless, it might be better considered a separate species; more study required. Proposed race *incognita* probably best treated as a synonym of *isaurae*. Four subspecies recognized.

Subspecies and Distribution.

C. u. melanorrhoea Salvin, 1865 - Caribbean slope of Nicaragua and Costa Rica.

C. u. isaurae (Gould, 1861) - Caribbean slope of Panama to extreme NW Colombia; locally on Pacific slope in W & C Panama, and extensively in E Panama.

C. u. urochrysis (Gould, 1861) - extreme SE Panama, NC & W Colombia, and extreme NW Ecuador.

C. u. intermedia E. Hartert & C. Hartert, 1894 - subtropical zone of SW Ecuador.

Descriptive notes. 10.5-12 cm; male 7-1 g, female 6-1 g. Conspicuous red or pink feet (no definite information for *intermedia*); bill black with basal half or more of mandible pinkish. Male of nominate metallic green above, glittering green below with tail bronze-green, undertail-coverts fluffy, white, elongated. Female is grey below, flecked with green laterally, the undertail-coverts greyish-white, the lateral rectrices tipped grey. Immature male typically duller below than adults; young of both sexes with buffy to cinnamon fringes on crown, nape and rump feathers. Male *melanorrhoea* glittering dark green below, belly

dusky bronze, undertail-coverts sooty blackish, less elongated; dark bronzy-green above, uppertail-coverts purplish-bronze, tail purplish-black; female darker grey below, more heavily flecked green than in other races, tail as male but lateral rectrices grey-tipped. In race *isaurae*, male is glittering bluish-green below with blue throat and breast, tail brighter bronze; female paler, more immaculate grey below. Birds from near Colombia-Panama border ("*incognita*") intermediate, most like nominate; male of *intermedia* has breast greenish-blue, belly grey, tail dark blue.

Habitat. Understorey and middle strata of humid forest, forest borders, adjacent tall second growth and semi-open habitats (cacao plantations, shaded gardens, etc.); avoids open areas. Occurs from sea-level to 700 m in Costa Rica, 900 m in Colombia.

Food and Feeding. Both sexes visit mainly flowers of large herbs (*Renalemia*, *Costus* and especially *Heliconia*) and shrubs (*Cephaelis*, *Malvaviscus*, *Acanthaceae*), as well as epiphytes of forest middle strata and subcanopy (*Ericaceae*, *Gesneriaceae*, bromeliads), and trees of the understorey or low along borders and gaps (*Inga*, *Symphonia*, *Hamelia*). Very aggressive and dominant at flowers, male in particular often defending territories at the richest clumps, especially of *Heliconia*. Flycatches frequently, mostly in sallies from perch in upper understorey; also makes sallies to glean arthropods from foliage, and less often hovers to glean (especially female); arthropods taken include mostly flies and tiny wasps with small numbers of ants, homopterans, spiders and other taxa.

Breeding. In Costa Rica, Dec or (more often) Feb-May; Feb-Apr in W Colombia. Breeding male often defends flower-centred territories which are visited by females. Nest a deep, compact cup of light-coloured plant down and fibres, and spiders' webs, heavily decorated on outside with green moss and a few bits of lichen. 0.5-1.5 m above ground in shrub near stream or trail in forest understorey (*melanorrhoea*). No further information.

Movements. In *melanorrhoea*, mainly local movements in response to seasonal shifts in flowering; no data for other races.

Status and Conservation. Not globally threatened, CITES II. In some parts of range such as Costa Rica and N Colombia, species has suffered considerable loss of forest habitat, but it remains locally common at some sites. Has been recorded at Finca La Selva and Cahuita National Park (Costa Rica) and at El Placer (Ecuador). Status of race *intermedia* requires investigation.

Bibliography. Best *et al.* (1997), Butler (1979), Chapman (1917, 1926), Eisenmann & Howell (1962), Haffer (1967), Hilty & Brown (1986), Howell, S.N.G. & Webb (1995a), Howell, T.R. (1957), Parker *et al.* (1982), Ridgely & Gwynne (1989), Ridgway (1911), Slud (1964), Stiles (1975, 1980, 1995a, 1995b), Stiles & Skutch (1989), Stotz *et al.* (1996), Weathers & Stiles (1989), Wetmore (1968a), Wiedenfeld *et al.* (1985), Williams & Tobias (1994).

Genus LAMPORNIS Swainson, 1827

173. Blue-throated Hummingbird

Lampornis clemenciae

French: Colibri à gorge bleue

German: Blaukehlhympe

Spanish: Colibrí Gorgiazul

Taxonomy. *Ornismya Clemenciae* Lesson, 1829, Mexico.

Probably a sister-species of *L. amethystinus*. Hybridizes with both *Calypte anna* and *C. costae*. Differences between races are weak and require more study. Two subspecies currently recognized.

Subspecies and Distribution.

L. c. bessophilus (Oberholser, 1918) - SW USA (SE Arizona, S New Mexico) to NW Mexico (E Sonora, W Chihuahua).

L. c. clemenciae (Lesson, 1829) - S USA (SW Texas) and NE, C & S Mexico (Sierra Madre Oriental and central plateau S to Oaxaca).

Descriptive notes. c. 13 cm; male c. 8 g, female c. 6-5 g. Male has medium sized, slightly decurved black bill; crown green, postocular stripe white and dusky grey auriculars; back greyish-green; gorget is iridescent blue often bordered by a white "moustache"; underparts dusky grey; tail rounded, blue-black with broad white tips to outer rectrices. Female similar to male except throat is dusky grey. Immature resembles adult female, immature male with some iridescent blue feathers on throat. Race *bessophilus* has shorter bill, plumage above generally duller, below generally paler.

Habitat. In USA and N Mexico found primarily in riparian canyons at altitude of between 1500 and 2500 m. Associated primarily with pine, oak, cypress, sycamore and maple. Will stray from riparian zones to more arid slopes and disturbed areas to feed. In other parts of Mexico has wider altitudinal range (1500-3500 m) and perhaps weaker association with riparian habitats during breeding season. Descends as low as 500 m during winter when food at higher altitude is scarce.

Food and Feeding. Floral nectar from several plant species, including *Lobelia*, *Nicotinia*, *Penstemon* and *Salvia*; also small arthropods, such as Hemiptera, small beetles, flies and wasps. Exclusive access to food is maintained by intense territorial behaviour. Its large size allows easy dominance over other hummingbird species.

Breeding. In USA mainly between May and Jul. In Mexico the breeding period is more variable, possibly corresponding to specific flowering periods. Nests are constructed in places where completely covered from above, including under the eaves of houses. Nest is a cup lined with soft downy plant materials, exterior is covered with lichen, moss, or bark glued in place with spiderweb. Clutch size 2; incubation 15-18 days by female; fledging at 24-29 days. At least one documented case of 3 broods during one breeding season.

Movements. Birds in S Mexico are resident although some engage in altitudinal migration during winter. In N & C Mexico birds migrate north to breeding grounds, arriving in Mar and Apr. Departure on autumn migration is more variable, occurring between Aug and Oct.

Status and Conservation. Not globally threatened, CITES II. In USA, artificial feeders maintain unusually large populations that exceed available natural food resources. Species is susceptible to natural or unnatural disturbances like forest fires because habitat is often restricted to the higher elevations of isolated mountain ranges. Habitat destruction could prove to be a significant concern in the future throughout range.

Bibliography. Baich & Harrison (1997), Baldrige *et al.* (1983), Bené (1947), Bent (1940), Binford (1989), Cottam & Knappen (1939), DeGraaf & Rappole (1995), Des Granges & Grant (1980), Friedmann *et al.* (1950), Hejl *et al.* (1995), Howell & Webb (1995a), Johnson (1997), Kaufman (1996), Kuban & Neill (1978, 1980), Lasiewski & Lasiewski (1967), des Lauriers (1994), Lyon (1976), Lyon & Chadek (1971), Lyon *et al.* (1977), Marshall (1957), Mayr & Short (1970), Miller (1955), Nosedal (1981), Phillips *et al.* (1964), Pimm (1978), Pimm *et al.* (1985), Powers & Conley (1994), Price *et al.* (1995), Rappole *et al.* (1995), Ridgway (1911), Rising (1965), Rowley (1984), Rutgers & Norris (1972), Schuchmann (1985b), Small (1994), Spofford (1980), Stotz *et al.* (1996), Urban (1959), Wagner (1951, 1952, 1957b).

174. Amethyst-throated Hummingbird

Lampornis amethystinus

French: Colibri à gorge améthyste **German:** Rotkehlhympe **Spanish:** Colibrí Amatistino
Other common names: Cazique Hummingbird; Margaret's/Violet-throated Hummingbird (*margaritae*)

Taxonomy. *Lampornis amethystinus* Swainson, 1827, Temascaltepec and Real del Monte, Mexico. Taxonomy somewhat confused, and precise distributions of races not well known. Probably a sister-species of *L. clemenciae*. Race *margaritae* (including *salvini* and *nobilis*) sometimes suggested as possible separate species. Proposed race *brevirostris* doubtfully distinct from *margaritae*. Race *circumventris* known only from type locality. Five subspecies recognized.

Subspecies and Distribution.

L. a. amethystinus Swainson, 1827 - W, C & E Mexico (S Nayarit, S Nuevo León and S Tamaulipas to Veracruz and E Oaxaca).

L. a. margaritae (Salvin & Godman, 1889) - SW Mexico (Michoacan, Guerrero, W Oaxaca).

L. a. circumventris (Phillips, 1966) - S Mexico (San Gabriel Mixtepec, in SW Oaxaca).

L. a. salvini (Ridgway, 1908) - highlands of S Mexico (Chiapas), Guatemala and El Salvador.

L. a. nobilis Griscom, 1932 - highlands of Honduras.

Descriptive notes. 11.5-12.5 cm; male 5-7.8 g, female 5-5.8 g. Male has slightly decurved black bill; crown dark green, auriculars dusky grey, postocular stripe white, rest of upperparts grey, rump bronzy, uppertail-coverts blackish; underparts dusky grey washed green, gorget iridescent rosy pink, undertail-coverts fringed pale buff; tail slightly forked, bluish-black, outer rectrices tipped grey. Female similar, throat pale dusky cinnamon. Immature resembles adult female, immature male with some pink feathers on throat. Male of race *circumventris* differs in pinkish-purple throat and generally paler coloration of underparts;

margaritae is generally darker in plumage coloration, throat violet-purple but extremely variable; *salvini* is darker and smaller, throat reddish; *nobilis* is similar to previous race but smaller and darker, throat reddish.

Habitat. Edges and interior of humid evergreen and pine-oak forest, at 900-3000 m.

Food and Feeding. Feeds on nectar of flowering *Centropogon affinis*, *Fuchsia minutiflora*, *Penstemon kunthii*, *Rigidella orthantha*, *Salvia caciaefolia*, *S. cinnaberrina*, *S. nervata* and *Satureja*. Feeds by trap-lining. Insects are caught in the air by hawking.

Breeding. Oct-Dec, May-Jul. Nest is cup-shaped, made out of moss, decorated with lichens, and attached to pendulous twigs in bushes or young trees 1.2-2.4 m above ground. Clutch size 2, incubation by female. No further information.

Movements. Sedentary.

Status and Conservation. Not globally threatened. CITES II. Generally common, but parts of habitat are under threat of deforestation; not known to accept man-made habitats. Regularly recorded at El Triunfo Biological Reserve and Lagos de Montebello (S Chiapas), Volcán de Fuego (Jalisco), Sierra de Atoyac (Guerrero), Cerro San Felipe (Oaxaca) and near San Cristóbal de las Casas (C Chiapas).

Bibliography. Anon. (1998a), Binford (1989), Contreras-Balderas (1997), Des Granges (1979), Des Granges & Grant (1980), Friedmann *et al.* (1950), Griscom (1932c), Hernández-Baños *et al.* (1995), Howell & Webb (1995a), Johnsgard (1997), Land (1970), Lara & Ornelas (1998), Lyon (1976), Monroe (1968), Phillips (1966), Ridgway (1911), Rowley (1966), Skutch (1967), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Wagner (1946a, 1957b), Wetmore (1941).

175. Green-throated Mountain-gem

Lampornis viridipallens

French: Colibri vert-d'eau **German:** Grünkehlnymphe **Spanish:** Colibrí Gorgiescamoso

Taxonomy. *T[rochilus] viridi-pallens* Bourcier and Mulsant, 1846, Cobán, Vera Paz, Guatemala. Forms a superspecies with *L. sybillae*, with which has been considered conspecific. Races *ovandensis* and *nubivagus* doubtfully valid, as differences weak; perhaps best treated as synonyms of nominate. Proposed race *connectens*, known by single specimen from N El Salvador, falls within normal range of variation of nominate. Four subspecies currently recognized.

Subspecies and Distribution.

L. v. amadoni Rowley, 1968 - Cerro Baul in Oaxaca (S Mexico); known only from type locality.
L. v. ovandensis (Brodkorb, 1939) - highlands of S Mexico (Chiapas) and NW Guatemala.
L. v. viridipallens (Bourcier & Mulsant, 1846) - highlands of Guatemala, extreme N El Salvador and W Honduras.
L. v. nubivagus Dickey & van Rossem, 1929 - El Salvador.

Descriptive notes. 11-12 cm; c. 5.4 g. Male has straight black bill; upperparts green, bronzy on rump, postocular stripe white, auriculars darkish, uppertail-coverts bluish-black; throat white with bluish-green iridescent discs, breast white, rest of underparts greyish, mottled green on sides and flanks, undertail-coverts dusky grey; tail slightly forked, central rectrices black, remainder pale grey. Female similar to male, upperparts generally emerald green, throat white. Immature resembles adult female, but throat pale buffy. Race *amadoni* is darker, less bronzy on rump, central rectrices black; *ovandensis* differs in having less green areas

on sides of breast and flanks; in *nubivagus* upperparts are dark green, rump intense bronze.
Habitat. Edge and interior of humid evergreen and pine-oak forest, at 900-2700 m. Forages from low to higher strata.

Food and Feeding. No specific food plants have been recorded. Presumably feeds on nectar of similar flowering plants as *L. amethystinus*, like Campanulaceae, Onagraceae, or *Salvia*. Insects are caught in the air by hawking.

Breeding. Mar-Apr, Jun-Jul. No further data available.

Movements. Sedentary.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species; present in North Central American Highlands EBA. Generally common, though parts of habitat are under threat of deforestation; not known to tolerate man-made habitats. Regularly recorded at El Triunfo Biological Reserve and Lagos de Montebello (S Chiapas).

Bibliography. Anon. (1998a), Berlioz (1938), Binford (1989), Dickey & van Rossem (1929), Edwards & Lea (1955), Friedmann *et al.* (1950), González-García (1993), Hernández-Baños *et al.* (1995), Howell & Webb (1995a), Land (1970), Monroe (1963, 1968), Paynter (1957), Rowley (1966, 1968), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Wagner (1957b).

176. Green-breasted Mountain-gem

Lampornis sybillae

French: Colibrí de Sybil **German:** Grünbrustnymphe **Spanish:** Colibrí de Sibila

Taxonomy. *Delatratia sybillae* Salvin and Godman, 1892, Matagalpa, Nicaragua. Forms a superspecies with *L. viridipallens*, with which has been considered conspecific. Monotypic.
Distribution. Highlands of E Honduras and NC Nicaragua.

Descriptive notes. 11-12 cm. Male has straight black bill, whitish postocular stripe and dark auriculars, upperparts green, rump bronzy; glittering green gorget with extensive green underparts; tail fairly long and broad, squared to slightly forked, outer rectrices contrasting white. Female similar to male, gorget not clearly defined, throat washed buff. Immature male resembles female but throat whitish, only faintly washed buff.

Habitat. Highland humid evergreen forest, forest edges, oak woodland, brush and thickets, at 1400-2200 m.

Food and Feeding. No information available.

Presumably feeds on similar flowers to *L. viridipallens*.

Breeding. No information available.

Movements. No reliable information available. Presumably sedentary.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species; present in North Central American Highlands EBA. Common to fairly common throughout much of its limited range. Species very poorly known; extensive research required.

Bibliography. Anon. (1998a), Berlioz (1938), Hernández-Baños *et al.* (1995), Howell & Webb (1995a), Monroe (1963, 1968), Stattersfield *et al.* (1998), Stotz *et al.* (1996).

PLATE 60

177. White-bellied Mountain-gem

Lampornis hemileucus

French: Colibri à gorge lilas German: Veilchenkehlnympe Spanish: Colibrí Gorgivioleta

Taxonomy. *Oreopyra hemileuca* Salvin, 1865, Turrialba, Costa Rica. Monotypic.

Distribution. Highlands on Caribbean slope from NC Costa Rica to W Panama.

Descriptive notes. 10-11 cm; male 6-2 g, female 5-1 g. Bill black, feet dark flesh-coloured. Adult male has crown and face glittering green, postocular stripe white, rest of upperparts bronzy-green, uppertail-coverts and tail bronzy, lateral rectrices with a dusky grey subterminal band; centre of throat blue-violet, remainder of underparts white, speckled laterally with green. Female similar but crown less glittering green and lacks blue-violet on throat; lateral rectrices tipped grey. Immature male lacks glittering green on head, violet of adult throat replaced by dull bronze; young of both sexes with rusty fringes on feathers of head, back, rump and sides.

Habitat. Canopy and edge of cool, very wet subtropical forest, descending to shrub level along borders, gaps and areas of open understorey; infrequent in adjacent second growth and semi-open vegetation. Breeds at 700-1400 m in Costa Rica.

Food and Feeding. Visits flowers of trees (*Calliandra*, *Clusia*, *Inga*) and shrubs (*Acanthaceae*, *Besleria*, *Cephaelis*), but especially fond of those of epiphytes (*Ericaceae*, *Columnnea*). Notably aggressive when feeding, dominating other species at flowering trees; male often defends rich clumps of flowers of large epiphytes (*Cavendishia*, *Thibaudia*). Frequently flycatches by sallying from perch in canopy or along edge, less often (mostly females) glean arthropods from foliage.

Breeding. Aug or Sept-Mar in Costa Rica. Breeding male often advertises flower-centred territories by complex, warbling song. Nest undescribed.

Movements. Following breeding, at least part of population descends to lower elevations, regularly to 400-600 m.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species: present in Costa Rica and Panama Highlands EBA. Locally very common. Large areas of its wet subtropical forest habitat remain, including tracts in several protected areas such as Braulio Carrillo, Tapanti and Amistad National Parks in Costa Rica.

Bibliography. Anon. (1998a), Fogden (1993), Hernández-Baños *et al.* (1995), Monroe (1963), Renjifo *et al.* (1997), Ridgely & Gwynne (1989), Slud (1964), Stattersfield *et al.* (1998), Stiles (1985b, 1985c), Stiles & Skutch (1989), Stotz *et al.* (1996), Wetmore (1968a).

178. Variable Mountain-gem

Lampornis castaneiventris

French: Colibri à ventre châtain German: Weißkehlnympe Spanish: Colibrí Variable
Other common names: Chestnut-bellied Mountain-gem; Purple-throated Mountain-gem (*calolaemus*); Grey-tailed Mountain-gem (*cinereicauda*); White-throated Mountain-gem (*castaneiventris*)

Taxonomy. *Trochilus* (—?) *castaneiventris* Gould, 1851, Cordillera de Chiriquí, 6000 feet [c. 1830 m], Panama.

Classification much disputed: three essentially parapatric groups with distinct male plumages hybridize to uncertain extent, probably very limited, where their ranges abut; many previous reports of hybrids may refer to young birds. The groups are: purple-throated, blue-tailed *calolaemus* (with *pectoralis* and *homogenes*); white-throated, grey-tailed *cinereicauda*; and white-throated, blue-tailed *castaneiventris*. Racial allocation of purple-throated birds of the Pacific coastal range of S Costa Rica (*calolaemus* or *homogenes*) is uncertain at present. Where white- and purple-throated forms occur on the same slopes, the former tend to occupy higher elevations. Different authors have advocated recognizing one, two (white-throated as opposed to purple-throated races), or three species. Females of all groups are very similar. More study of this complex is needed. Five subspecies recognized.

Subspecies and Distribution.

L. c. pectoralis (Salvin, 1891) - extreme S Nicaragua to NC Costa Rica.

L. c. calolaemus (Salvin, 1865) - Cordillera Central and extreme N Cordillera de Talamanca (C Costa Rica).

L. c. cinereicauda (Lawrence, 1867) - Cordillera de Talamanca (S Costa Rica).

L. c. homogenes Wetmore, 1967 - Pacific slope of S Costa Rica (probably) and W Panama.

L. c. castaneiventris (Gould, 1851) - extreme W Panama.

Descriptive notes. 10-11.5 cm; male 5-7-6-2 g, female 4-7-5-1 g. Bill medium-length, straight and black. Male of nominate has crown glittering pale blue-green, gorget white with a few blue or purple feathers along lower margin; conspicuous white postocular stripe; rest of upperparts bright bronzy-green; chest glittering pale green, belly grey, notched tail blue-black. Female lacks bright crown and gorget, entirely cinnamon-rufous below; tail green with blue-black subterminal band and white tips on lateral rectrices. Immature male has crown, throat and chest dull dusky green; young female with rusty fringes on crown and face

feathers. Race *pectoralis* is smaller and darkest below of all races, male with breast glittering dark green; *calolaemus* differs from nominate mainly in purple gorget and turquoise forehead of male; *cinereicauda* similar to nominate but male has forehead turquoise, tail ash grey, and green areas duller and more bronzy in females; *homogenes* is dark below in both sexes. First gorget feathers of

young purple-throated male paler purple to brownish, often with extensive pale bases; of young white-throated male, white to buffy brown, sometimes with faint purplish tinge.

Habitat. Wet subtropical forest (purple-throated races) to colder montane forests, especially of oak (white-throated races). Race *pectoralis* occurs at 800-2000 m; other purple-throated races mostly 1200-2500 m; white-throated races mostly 1850-3000m, in areas where they co-occur, purple-throated and white-throated forms replace each other, more or less abruptly, at elevations below and above c. 2000 m respectively. All forms found mainly in canopy and along edges of mountain forests, with female nesting more in understorey, both sexes occurring down to shrub level at edges and gaps, in adjoining tall second growth, or semi-open and man-made habitats.

Food and Feeding. Male in particular prefers to take nectar at flowers of large epiphytes (*Ericaceae*, *Gesneriaceae*, bromeliads) in middle strata and lower canopy of forest; female more often visits flowers of a variety of shrubs (*Acanthaceae*, *Gesneriaceae*, *Rubiaceae*); both sexes may visit flowers of trees (*Clusia*, *Inga*) or shrubs (*Stachytarpheta*) along edges of coffee plantations or second growth. Aggressive and dominant at flowers, male frequently defending richest clumps. Takes many arthropods, mainly by flycatching, but female in particular often gleans them from foliage, tree trunks, branches and sometimes spiders' webs.

Breeding. Mostly rainy season, Oct-Apr (or June in some forms, notably *pectoralis*). Nest is compact cup of pale or brownish plant down, fine fibres, treefern scales, sprigs of fine liverworts and cobwebs, more or less heavily decorated on outside with bits of moss and lichen, 0.5-3.5 m up in shady forest understorey, usually beside a gap or trail. Clutch size 2; incubation 17-18 days; fledging period 22-23 days.

Movements. Most populations descend to lower elevations following breeding, down to 1200-1500 m (*cinereicauda*) or 300-500 m (*calolaemus*).

Status and Conservation. Not globally threatened. CITES II. Over most parts of range one of the commonest mountain hummingbirds, and protected areas exist in the ranges of all races. The major exceptions are the purple-throated forms of the Pacific slope of S Costa Rica and possibly adjacent Panama, which are poorly known taxonomically and threatened by deforestation; the contact area between *calolaemus* and *cinereicauda* in SC Costa Rica, important for studies on their status, has also been severely deforested. In Costa Rica, has been recorded in several protected areas such as Tapanti National Park and Monteverde Biological Reserve.

Bibliography. Anon. (1998a), Berlioz (1949a), Blake (1958), Feinsinger (1976, 1977, 1980), Feinsinger & Bushy (1987), Feinsinger & Tiebout (1991), Feinsinger, Murray *et al.* (1988), Feinsinger, Tiebout & Young (1991), Feinsinger, Tiebout, Young & Murray (1991), Hartman (1957), Linhart *et al.* (1987), Murray *et al.* (1987), Ridgely & Gwynne (1989), Ridgway (1911), Skutch (1967), Slud (1964), Snow (1977b), Stiles (1985b, 1985c), Stiles & Skutch (1989), Stotz *et al.* (1996), Wetmore (1968a).

Genus BASILINNA Boie, 1831

179. Xantus's Hummingbird

Basilinna xantusii

French: Saphir de Xantus German: Schwarzstirn-Saphirkolibri Spanish: Colibrí de Xantus
Other common names: Black-fronted Hummingbird

Taxonomy. *Amazilia Xantusii* Lawrence, 1860, near Cape San Lucas, Baja California Sur, Mexico. Genus often merged into *Hylocharis*, though external morphology suggests closer relationship to *Lampornis*. Forms a superspecies with *B. leucotis*. Monotypic.

Distribution. S Baja California; also Cerralvo I and perhaps sporadically on San José I (Gulf of California). Recent vagrant to S California (USA), where attempted to nest.

Descriptive notes. 8-9 cm; 3-2-4-0 g. Male has bill straight, moderately long, red with black tip; head blue-black with white postocular stripe above black auriculars, throat glittering green, breast and belly cinnamon-rufous, nape and back green, wings dusky purple; tail squared, purplish-chestnut with central rectrices edged green. Female duller than male, has bill black above, basally red below; crown dull green instead of black, underparts including throat buffy, eyestripe brown instead of black, bordered above by white postocular stripe; tail mostly rufous but central rectrices green and outer rectrices with dark subterminal

markings and paler tips. Adults are in freshest plumage in northern summer and autumn, duller in spring. Immature male resembles female except for some green on throat.

Habitat. In cape region, occurs in several habitats including oak-pine forest (*Quercus devia*, *Pinus cembroides*) from 1800 to 2200 m in Sierra de La Laguna, and cape deciduous forest, a thorny, heavily grazed association of shrubs, trees and columnar cacti. Fond of water, streams and canyons, therefore usually absent from low elevation desert where *Calypte costae* is seasonally common. Occurs on highest mountains of cape in coldest weather; also in orchards and irrigated shrubbery, sometimes along coast (San José del Cabo, Todos Santos, but not xeric La Paz). On Cerralvo island, prefers higher elevations.

Food and Feeding. In pine-oak forest, the small tubular flowers of madrone trees (*Arbutus peninsularis*) are a critical nectar resource during late winter; other food plants are *Castilleja bryantii*, *Lepechinia hastata*, *Behria tenuiflora*, *Lobelia laxiflora*, *Calliandra peninsularis* and *Mirabilis jalapa*. In cape deciduous forest, visits *Fouquieria diguetii*, which flowers for several months. Gleans insects from pines and oaks.

Breeding. In Sierra de la Giganta, from Feb to at least Apr; nests low in various trees (cottonwood, willow, avocado, lemon). In Sierra de La Laguna, nests Jul-Sept, usually in small oaks. Nest is relatively large, composed of fine plant down, dried flower heads, plant fibres, bark strips, lichens from oaks (when available), bound with spider web. Clutch 2 eggs; incubation 15-16 days by female; fledging period 20-22 days.

Movements. Sedentary.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species; present in Baja California EBA. Occurs almost exclusively in Baja California Sur, where only one other hummingbird species, *Calypte costae*, is present as a potential competitor. Rather versatile in habitat use, although not as well adapted to xeric conditions as is *C. costae*. Considered fairly common to common in cape region in appropriate habitat, more local further north.

Bibliography. Anon. (1998a), Arriaga *et al.* (1990), Banks (1963, 1967), Bent (1940), Brewster (1902), Brown & Bowers (1985), Bryant (1889), Cody (1983), Davis, J. (1959), Friedmann *et al.* (1950), Grinnell (1928), Hainebach (1992), Howell & Webb (1995a), Johnsgard (1997), Lamb (1925), Mayr & Short (1970), Ridgway (1911), Small (1994), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Wagner (1946a), Wiggins (1960), Wilbur (1987).

180. White-eared Hummingbird

Basilinna leucotis

French: Saphir à oreilles blanches

Spanish: Colibrí Orejiblanco

German: Purpurstirn-Saphirkolibri

Taxonomy. *Trochilus leucotis* Vieillot, 1818, Brazil; error = Orizaba, Veracruz.

Genus often merged into *Hylocharis*, though external morphology suggests closer relationship to *Lamprolaima*. Forms a superspecies with *B. xantusii*. Three subspecies recognized.

Subspecies and Distribution.

B. l. borealis (Griscom, 1929) - N Mexico (Sonora, Chihuahua, Tamaulipas); rarely to SW USA (SE Arizona).

B. l. leucotis (Vieillot, 1818) - highlands of C & S Mexico to Guatemala.

B. l. pygmaea Simon & Hellmayr, 1908 - highlands of El Salvador, Honduras and Nicaragua.

Descriptive notes. 9-10 cm; male c. 3-6 g, female c. 3-2 g. Male has straight bill, red, tipped black; forehead glittering violet, white postocular stripe, auriculars blackish, rest of upperparts green with lower back and upper-tail-coverts fringed rufous; chin glittering violet, gorget iridescent turquoise green, rest of underparts greyish-green; tail slightly forked, central rectrices green, outer blackish, tipped green. Female has straight bill, upper mandible black, lower red, tipped dark; crown brownish-green, white postocular stripe, auriculars blackish, rest of upperparts green, lower back and uppertail-coverts fringed rufous; throat white with green discs, rest of underparts whitish mottled green; tail centrally green, outer rectrices fringed brown and tipped white. Immature resembles adult female, has rectrices largely tipped white. Race *borealis* is larger, underparts greyer, less green; *pygmaea* is smaller, green gorget smaller, underparts whitish heavily mottled green, tail greenish with rufous fringes.

Habitat. Pine-oak forest, pine-evergreen forest, clearings, at 1200-3500 m. Forages in low to middle strata.

Food and Feeding. Feeds on nectar of flowering *Agave*, *Bidens*, various *Salvia* species, *Penstemon*, *Cuphea* and others. Arthropods are caught in the air by hawking and extracted from flowers. Territorial.

Breeding. Mar-Aug in N & C Mexico; May-Aug and Nov-Feb, possibly all year round, in S Mexico; Aug-Dec for race *pygmaea*. Cup-shaped nest is built out of soft plant down, mainly downy fibres from oak leaves and moss, exteriorly decorated with greyish lichens, placed 1-6-6 m above ground preferably in oak (Mexico) or *Baccharis vacinoides* (Guatemala). Sometimes several nests are built within a short distance of each other; often built on previous year's nest. Clutch size 2; incubation 14-16 days by female; fledging at 23-28 days. Up to 3 broods may be raised in Mexico, 2 in other areas.

Movements. Some migratory activity in northern part of range, where species is most abundant from Apr to Oct, after which not recorded in USA, while in N Mexico less numerous between Nov and Mar. Southern population shows no migratory activity, although some altitudinal dispersal after breeding and following flowering plants may occur.

Status and Conservation. Not globally threatened. CITES II. Common and widespread throughout much of range. No immediate threat recorded; however, parts of its forest habitat are under threat of deforestation; accepts disturbed areas such as clearings.

Bibliography. Amadon & Eckelberry (1955), Arizmendi *et al.* (1996), Baeppler (1962), Baitech & Harrison (1997), Bent (1940), Binford (1989), Cottam & Knappen (1939), Davis (1953), DeGraaf & Rappole (1995), Des Granges (1979), Des Granges & Grant (1980), Desselberger (1932), Dickey & van Rossem (1938), Edwards & Lea (1955), Ely (1962), Friedmann *et al.* (1950), Greenberg *et al.* (1993), Griscom (1934), Hejl *et al.* (1995), Howell & Webb (1995a), Hubbard (1978), Johnsgard (1997), Kaufman (1996), Lea & Edwards (1950), Lyon (1976), Lyon & Chadek (1971), Martínez del Río & Eguarte (1987), Mayr & Short (1970), Monroe (1968), Moore (1939c), Ranta (1986), Ridgway (1911), Rowley (1966, 1984), Russell (1964), Schaldach (1963), Skutch (1935, 1945, 1951, 1972, 1976), Stotz *et al.* (1996), Sutton & Burleigh (1940), Udvardy (1983), Wagner (1942, 1946a, 1957b, 1959).

Genus LAMPROLAIMA Reichenbach, 1854

181. Garnet-throated Hummingbird

Lamprolaima rhami

French: Colibrí à gorge grenat

German: Granatkehlkolibri

Spanish: Colibrí Alicastaño

Taxonomy. *Ornismya Rhami* Lesson, 1838, Mexico.

Possibly belongs in *Basilinna*. Proposed races *occidentalis* (Guerrero) and *saturation* (Honduras and N El Salvador) based on colour and size variation, but both patterns are either age-dependent or clinal in character and thus unsuitable criteria for subspecific recognition. Monotypic.

Distribution. C & S Mexico (Guerrero, Puebla and W Veracruz S through Oaxaca to Chiapas) S to Guatemala, El Salvador and Honduras.

Descriptive notes. 12-12.4 cm; 5-6-7-1 g. Male has short straight black bill; upperparts iridescent green, postocular spot white; throat shining rose pink, breast iridescent violet-blue, rest of under-

parts blackish, mottled green on flanks; remiges rufous, tipped dark brown; tail dark purple, outer rectrices finely tipped grey. Female upperparts like male; below dusky grey, usually pinkish dots on throat; tail duller, with white tips to outer rectrices. Immature female similar to adult female but with buff fringes on head feathers; immature male similar to adult female but with darker underparts, buff fringes to bluish chest feathers, and rufous parts on remiges smaller than in adult male.

Habitat. Upper tropical forest, cloudforest, forest edge, pine-oak forest and scrub, at 1200-3000 m on Atlantic and Pacific slope; most numerous at 1500-2300. In Honduras, does not occur below 1600 m. Forages 1-10 m above the ground.

Food and Feeding. Nectar of flowering shrubs, *Inga* and *Erythrina* trees. Insects are caught in the air by hawking. Male occupies feeding territories.

Breeding. Apr-May (Atlantic slope), Dec-Mar (Pacific slope); nests have also been found in Sept. Bulky cup-shaped nest is composed of moss, parts of leaves, and pine needles, lined with soft plant fibre, attached to roots in banks of washed-out creek beds. Clutch size 2, incubation by female. No further information.

Movements. Sedentary; birds move to higher altitudes (above 1500 m) during reproduction period.

Status and Conservation. Not globally threatened. CITES II. A locally common bird associated with cloudforest and pine-oak forest; readily accepts modification of habitat by man, if patches of forest remain. Frequently recorded in Sierra de Atoyac (Guerrero), Cerro San Felipe (Oaxaca) and Lagos de Montebello (S Chiapas).

Bibliography. Anon. (1998a), Baeppler (1962), Binford (1989), Friedmann *et al.* (1950), Griscom (1932c, 1934), Howell & Webb (1995a), Johnsgard (1997), Land (1970), Monroe (1968), Phillips (1966), Ridgway (1911), Rowley (1966), Stone (1932), Stotz *et al.* (1996), del Toro (1941), Wagner (1957b), Wetmore (1941).

Genus ADELOMYIA Bonaparte, 1854

182. Speckled Hummingbird

Adelomyia melanogenys

French: Colibrí moucheté

German: Schwarzhörlkolibri

Spanish: Colibrí Jaspeado

Other common names: Pipita

Taxonomy. *Trochilus melanogenys* Fraser, 1840, Bogotá, Colombia.

Systematic position poorly understood; the genera *Phlogophilus*, *Anthocephala* and *Urastictes* have been suggested as close relatives, some authors even considering all four to be congeneric; however, because monophyly of these four is doubtful, the monotypic status of *Adelomyia* is maintained. Seven subspecies recognized.

Subspecies and Distribution.

A. m. aeneosticta Simon, 1889 - N & C Venezuela.

A. m. melanogenys (Fraser, 1840) - Andes of W Venezuela (Mérida) and E Colombia S through E Andes to SC Peru.

A. m. cervina Gould, 1872 - W & C Andes of Colombia.

A. m. connectens Meyer de Schauensee, 1945 - Huila (S Colombia).

A. m. maculata Gould, 1861 - Ecuador to N Peru.

A. m. chlorospila Gould, 1872 - SE Peru.

A. m. inornata (Gould, 1846) - Yungas of Bolivia and NW Argentina (Salta, Jujuy).

Descriptive notes. 8.5-9 cm; male 4-9 g, female 4-2 g. Sexes alike. Short straight black bill; blackish cheeks, buffy white streak behind the eye; upperparts bronzy-green; speckled dusky on throat, greenish on breast, rest of underparts dull white or buff; tail slightly forked, bronzy-purple, all but the two central rectrices tipped white or buff. Immature with brown fringes on feathers of head and lower back. Race *cervina* larger than nominate, with bill shorter, throat finely spotted brown, underparts richer buff; *connectens* intermediate between *cervina* and *maculata*, tail with small buff tips; *aeneosticta* smaller than nominate.

paler below, speckles restricted to upper throat; *maculata* with large buffy portions on inner webs of tail feathers; *chlorospila* has throat discs deep green; *inornata* with blue discs on throat.

Habitat. Humid forest, forest borders and along watercourses, at 1000-2500 m, commonest around 2000 m. Forages solitarily and rather low down in dense thickets.

Food and Feeding. Nectar of flowering shrubs and vines, including *Lobelia*, *Fuchsia*, *Psammisia*, *Palicourea* and *Bomarea*. Insects are caught by hawking or gleaned from the surface of leaves.

Breeding. Nests have been found all year round, chiefly from Jan to mid-May. Bulky cup-shaped nest of moss and cobweb, lined with fine plant fibre, is built on moss-covered trunks or on rocky ridges, occasionally at the entrance of caves, at height of 1-3 m. Clutch size 2; incubation 17-18 days, by female; chick is blackish with pale grey dorsal down; fledging period 20-24 days; young remain with adult female for 3-4 weeks. First breeding in second year.

Movements. Mainly sedentary; individuals may disperse to lower altitudes after the breeding period.

Status and Conservation. Not globally threatened. CITES II. A very common hummingbird of moderate elevations in the Andes. Particularly abundant in the W Andes above Cali (SW Colombia), with densities of at least 10-12 pairs/km². Occurs in Calilegua National Park, Argentina. Trapping for wild bird trade in Colombia and Ecuador was significant until the mid-1970's but has now apparently ceased.

Genus *PHLOGOPHILUS* Gould, 1860

183. Ecuadorian Piedtail

Phlogophilus hemileucurus

French: Colibri à queue mi-blanche **Spanish:** Colibrí Colipinto Ecuatoriano
German: Schwarzweißschwanz-Kolibri

Taxonomy. *Phlogophilus hemileucurus* Gould, 1860, banks of Río Napo, east Ecuador. Has occasionally been placed in genus *Adelomyia*; more information required to permit accurate assessment of most appropriate generic placement. Forms a superspecies with *P. harterti*. Monotypic. **Distribution.** S Colombia (W Putumayo) through E Ecuador to NE Peru (San Martín).

Descriptive notes. 7.3-7.6 cm; 2.2-3 g. Sexes alike. Short straight black bill, yellowish at base; crown greenish-brown, postocular spot white, rest of upperparts grass green; throat and breast white, spotted with green, white band across centre of breast, belly whitish; tail roundish, central pair of rectrices blue-green, remainder blue, white at base and broadly tipped white. Immature like adult but with buff fringes on head and neck feathers. **Habitat.** Forest edge and second growth in Andean foothills at 500-1200 m. Forages in low to middle strata, 2-4 m.

Food and Feeding. Nectar of flowering Rubiaceae, Ericaceae (especially *Psanmisia*), Gesneriaceae. When visiting flowers birds cling to corollas. Insects are mainly gleaned from the surface of plants. **Breeding.** Dec-Apr. Tiny cup-shaped nest of fine rootlets and pieces of fern leaf is built 2-3 m above ground in vines or underneath dense thickets overhanging steep roadsides. Clutch size 2; incubation by female. No further information. **Movements.** Sedentary, local altitudinal movements likely. **Status and Conservation.** Not globally threatened. CITES II. Currently considered Near-threatened. Restricted-range species: present in Ecuador-Peru East Andes EBA. Patchily distributed but common. Readily takes to altered habitat as long as forest patches and thickets of secondary growth remain. **Bibliography.** Balchin & Toyne (1998), Best *et al.* (1997), Butler (1979), Elgar (1975), Fitzpatrick & Willard (1982), Hilty & Brown (1986), King (1991), Meyer de Schauensee (1982), Olrog (1968), Parker & Parker (1982), Parker *et al.* (1982), Rahbek *et al.* (1995), Salaman & Mazariegos (1998b), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Williams & Tobias (1994), Zimmer (1951a).

184. Peruvian Piedtail

Phlogophilus harterti

French: Colibri de Hartert **German:** Hartertkolibri **Spanish:** Colibrí Colipinto Peruano

Taxonomy. *Phlogophilus harterti* Berlepsch and Stolzmann, 1901, Huanaypata, Peru. Has occasionally been placed in genus *Adelomyia*; more information required to permit accurate assessment of most appropriate generic placement. Forms a superspecies with *P. hemileucurus*. Monotypic. **Distribution.** C & SE Peru (S Huánuco, Pasco, Cuzco, Puno). **Descriptive notes.** 7.2-7.5 cm; 2.2-2.7 g. Sexes alike. Short straight black bill; upperparts green; throat and centres of breast and belly white, rest pale buff; tail roundish, central rectrices green, broadly tipped black, rest of rectrices buff with broad black diagonal band. Immature similar to adult but with buff fringes on feathers of head and neck. **Habitat.** Forest edge and secondary growth in Andean foothills at 900-1200 m, most numerous around 1000 m.

erally common in Andean foothills. Readily accepts modification of habitat by man, as long as patches of forest and secondary growth remain. A little-studied hummingbird. **Bibliography.** Meyer de Schauensee (1982), Olrog (1968), Parker *et al.* (1982), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Zimmer (1951a).

Genus *CLYTOLAEMA* Gould, 1853

185. Brazilian Ruby

Clytolaema rubricauda

French: Colibri rubis-émeraude **German:** Rubinkolibri **Spanish:** Colibrí Colirrojo

Taxonomy. *Trochilus rubricauda* Boddaert, 1783, Rio de Janeiro, Brazil. Sometimes placed in genus *Heliodoxa*; relationships unclear. Monotypic. **Distribution.** E Brazil, from Goiás through S Minas Gerais and Espírito Santo to Rio de Janeiro, São Paulo, Paraná, Santa Catarina and Rio Grande do Sul.

Descriptive notes. 10.8-11.3 cm; male 8.6-9.2 g, female 5.9-7.1 g. Melanistic individuals frequently occur. Male has medium-sized black bill; forehead and crown iridescent emerald green, nape green, rest of back golden bronze, postocular spot white; chin blackish, throat shining ruby red, breast iridescent emerald green, belly dark grey with green-centred feathers; inner rectrices golden bronze, rest rufous, edged bronze. Female grass green above, postocular spot white; below uniformly cinnamon. Immature similar to female, head feathers with buff fringes. **Habitat.** Forest interior, scrub, parks and banana plantations of the central Brazilian and Atlantic regions from sea-level to 1000 m, most numerous below 500 m. **Food and Feeding.** Nectar of native and introduced flowering shrubs, vines and trees, including *Helicteris*, *Dombeya*, *Citrus*, *Genipa*, *Musa*, *Eucalyptus* and *Inga*. Insects are caught in the air by hawking. Male, and to a lesser extent female defend feeding territories. **Breeding.** Nov-Mar. Cup-shaped nest of soft plant material, externally decorated with grey-green lichen, built on horizontal branch 3-10 m above ground. Clutch size 2; incubation 15-16 days, by female; chick black with sparse buff dorsal down; fledging at 25 days. First breeding in second year. **Movements.** Sedentary, locally with some seasonal altitudinal dispersal. **Status and Conservation.** Not globally threatened. CITES II. Common throughout range, and readily accepts man-made habitats like tree-filled gardens, parks and plantations. Occurs in several protected areas, such as Serra dos Órgãos and Itatiaia National Parks (Rio de Janeiro) and Nova Lombardia Biological Reserve (Espírito Santo). **Bibliography.** Belton (1984), Forrester (1993), Gonzaga *et al.* (1995), Grantsau (1988), Guix *et al.* (1992), Oniki (1996), Parker & Goerck (1997), do Rosário (1996), Ruschi (1949b, 1973d, 1981-1982, 1982a, 1986), Sargeant (1996), Sazima, I. *et al.* (1996), Sazima, M. *et al.* (1994), Scott & Brooke (1985), Sick (1993, 1997), Snow & Snow (1986), Snow & Teixeira (1982), Stotz *et al.* (1996), Tobias *et al.* (1993), Willis (1992).

PLATE 61

inches 2
cm 5

Genus *HELIODOXA* Gould, 1849

186. Gould's Jewelfront

Heliodoxa aurescens

French: Brillant à bandeau bleu

Spanish: Brillante Pechicastaño

German: Rotbrustbrilliantkolibri

Other common names: Jewelfront

Taxonomy. *Trochilus (Lampornis) aurescens* Gould, 1846, locality unclear (N Brazil and E Peru both suggested).

Until recently, often placed in monotypic genus *Polyplancta*, but morphological and behavioural parallels, supported by genetic analysis, suggest that species belongs in *Heliodoxa*; probably closely related to *H. schreibersii*. In past, occasionally placed in *Clytolaema*. Despite fairly extensive range, species shows only slight degree of variation. Monotypic.

Distribution. S Venezuela (S Amazonas, Bolívar) through Amazonian Colombia (W Putumayo, Vaupés, Amazonas), E Ecuador and E Peru (S to Puno) to N Bolivia (Pando, Beni, Cochabamba) and NW Brazil (Amazonas and S Pará possibly to R Madeira and N Mato Grosso).

Descriptive notes. 11-12 cm; c. 6.3 g. Bill straight, dark-coloured. Male with narrow frontlet glittering purplish-blue, upperparts shining grass green; underparts with chin, lores and upper throat velvety black, sides of neck and lower throat glittering golden green, bordered by a broad orange-rufous breast band, rest of underparts shining green; tail forked, central pair of tail feathers bronze-green, rest chestnut-edged and tipped bronze-green. Female similar but with crown green, chin feathers tipped buff; also generally duller in coloration with the throat greyish with green discs; short buff to chestnut malar stripe.

Habitat. Understorey of humid forest, especially near creeks and damp places, only rarely at forest edge; frequently in sandy areas, sometimes in *várzea* forests. Found in tropical lowlands at elevations between 150 and 400 m, only occasionally up to 600 m.

Food and Feeding. Mainly feeds on nectar of flowering shrubs but also takes insects in the air by hawking.

Breeding. Jun-Sept. Clutch size 2; incubation by female. No further information.

Movements. Sedentary.

Status and Conservation. Not globally threatened. CITES II. Generally varies from uncommon to locally common over its fairly sizeable range. Quickly accepts man-made habitats. Present in Tambopata Reserve, Peru.

Bibliography. Brown & Bowers (1985), Butler (1979), Cotton (1998a), Donahue (1994), Fitzpatrick & Willard (1982), Gerwin & Zink (1989), Gilliard (1941), Grantsau (1988), Hilty & Brown (1986), Meyer de Schauensee & Phelps (1978), Parker *et al.* (1985), Ruschi (1981-1982, 1986), Schmitt & Schmitt (1987), Schuchmann (1984b), Sick (1993, 1997), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Terborgh *et al.* (1984), Willard *et al.* (1991), Zimmer (1951a).

187. Fawn-breasted Brilliant

Heliodoxa rubinoides

French: Brillant rubinoïde

Spanish: Brillante Pechigamuza

German: Braunbauch-Brilliantkolibri

Other common names: Penny-throated/Lilac-throated Hummingbird, Lilac-breasted Brilliant

Taxonomy. *Trochilus rubinoides* Bourcier and Mulsant, 1846, Colombia.

Three subspecies recognized.

Subspecies and Distribution.

H. r. rubinoides (Bourcier & Mulsant, 1846) - C & E Andes of Colombia.

H. r. aequatorialis (Gould, 1860) - W slope of Andes in Colombia and Ecuador.

H. r. cervinularis (Salvin, 1892) - E slope of Andes in Ecuador and Peru.

Descriptive notes. 11-13 cm; 7.3-8.1 g. Bill straight, thick, black. Male shining bronzy-green above turning coppery on wing-coverts; below cinnamon-buff with green chin, green discs on throat and flanks and small rosy violet patch on centre of lower throat; tail is coppery green and slightly forked. Female resembles male but lacks glittering throat patch and green chin. Race *aequatorialis* differs from nominate in more golden green plumage, underparts more strongly spotted with green; *cervinularis* larger, has underparts almost entirely cinnamon-buff with fewer interspersed green discs, throat patch slightly smaller and paler.

Habitat. Understorey of wet and humid pre-montane forest, also along shady borders and forest edges; occasionally in more open habitats like pastures and gardens and in vicinity of towns, at altitudes of 1670-1830 m, locally and seasonally up to 2600 m. Records from Magdalena Valley suggest movements to lower elevations of 1000 m.

Food and Feeding. Takes nectar from a variety of food plants such as *Inga* and *Erythrina*; has been observed flycatching 3-6 m above ground.

Breeding. Jan-May (*rubinoides*, Colombia) or Sept-Jan (*aequatorialis*, Ecuador). Clutch size 2; incubation by female. First breeding in second year. No further information.

Movements. Sedentary with local altitudinal movements.

Status and Conservation. Not globally threatened. CITES II. Uncommon and local. Abundant above Cali (SW Colombia) with recorded densities of at least 3 pairs/km². Regularly reported from area between Nono and Mindo (NC Ecuador).

Bibliography. Best *et al.* (1997), Brown & Bowers (1985), Butler (1979), Chapman (1917, 1926), Davies *et al.* (1994), Fjeldså & Krabbe (1990), Gerwin & Zink (1989), Hilty (1985), Hilty & Brown (1986), Miller (1963), Parker & O'Neill (1980), Parker, Parker & Plenge (1982), Parker, Schultenberger *et al.* (1985), Rasmussen *et al.* (1996), Renjifo *et al.* (1997), Ruschi (1964b), Salaman & Mazariegos (1998b), Stotz *et al.* (1996), Williams & Tobias (1994), Zimmer (1951a).

188. Violet-fronted Brilliant

Heliodoxa leadbeateri

French: Brillant à front violet

Spanish: Brillante Frentivioleta

German: Violetstirn-Brilliantkolibri

Other common names: Blue-crowned Brilliant

Taxonomy. *Trochilus Leadbeateri* Bourcier, 1843, Caracas, Venezuela.

Apparently closest to *H. jacula*. An intergeneric hybrid has been recorded between present species and *Helianthangelus clarisse*. Four subspecies recognized.

Subspecies and Distribution.

H. l. leadbeateri (Bourcier, 1843) - N Venezuela in coastal mountains in Falcón, Yaracuy, Carabobo and Miranda.

H. l. parvula Berlepsch, 1887 - NW Venezuela (Táchira, Mérida, Barinas, Trujillo) and N. C & S Colombia (Serranía de Perijá and E Andes S to Macarena Mts, locally in Magdalena and Cauca Valleys, and possibly also N end of C Andes).

H. l. sagitta (Reichenbach, 1854) - E Ecuador and N Peru.

H. l. otero (Tschudi, 1844) - C & S Peru and NW Bolivia.

Descriptive notes. 11-13 cm; male 7.5-8.5 g, female 6.6-7.5 g. Bill almost straight, blackish. Male bronze-green above turning coppery on neck, forehead glittering blue; faint white malar streak and small white spot behind eye; underparts with glittering emerald green gorget, lower breast and belly dull bronze-green; tail deeply forked; central pair of rectrices bronze-green, next pair steel blue, tipped bronze, remainder entirely dark steel blue. Female has forehead glittering green, otherwise coppery green above; short white malar streak and small white spot behind eye; throat and breast thickly spotted with glittering green discs; underparts

mainly white turning buffy towards belly; tail shorter and less deeply forked than in male and feathers with narrow white tips. Race *parvula* differs in having frontal patch more violet than blue, coloration of belly paler and duller, central pair of tail feathers lighter and greener, the rest more blackish, and female with belly more cinnamon-buff; *sagitta* has a strong blue frontal patch, underparts and central rectrices resemble previous race in coloration, breast often with a bluish hue, female with belly almost whitish and a blue patch on crown; male *otero* has upperparts less coppery, female differs in having brownish belly, and lacks glittering green frontlet almost completely. **Habitat.** Pre-montane rainforest and cloudforest and forest edge, occasionally also scrub, small clearings, low open woodland, second growth, or coffee plantations. Mainly upper tropical and subtropical zones, but may sometimes ascend to lower border of temperate zone. Altitudinal distribution ranges from 400 to 2400 m. Replaced at lower elevations by *H. jacula*.

Food and Feeding. Takes nectar mainly at flowers in lower to middle strata (1-10 m) inside forest or near small openings at forest edge. Usually forages alone and does not gather in groups at flowering trees. A substantial part of the diet consists of insects obtained by flycatching.

Breeding. Jan-May. Clutch size 2; incubation by female. No further information.

Movements. Sedentary.

Status and Conservation. Not globally threatened. CITES II. Reported estimates of abundance are to some extent contradictory, but species appears to be quite common, at least locally. Has been recorded at Henri Pittier National Park (N Venezuela).

Bibliography. Best *et al.* (1997), Bloch *et al.* (1991), Bond & Meyer de Schauensee (1943), Brown & Bowers (1985), Butler (1979), Chapman (1917, 1926), Collins (1972b), Davies *et al.* (1994), Fjeldså & Krabbe (1990), Gerwin & Zink (1989), Graves & Zusi (1990a), Hilty & Brown (1986), Meyer de Schauensee & Phelps (1978), Parker *et al.* (1982), Remsen & Traylor (1989), Ridgely & Gaulin (1980), Rutgers & Norris (1972), Salaman & Mazariegos (1998a, 1998b), Stotz *et al.* (1996), Williams & Tobias (1994), Zimmer (1930, 1951a).

189. Velvet-browed Brilliant

Heliodoxa xanthogonys

French: Brillant à couronne verte

German: Grüner Brilliantkolibri

Spanish: Brillante de Tepui

Taxonomy. *Heliodoxa xanthogonys* Salvin and Godman, 1882, Merumé Mountains, Guyana.

Southern populations apparently represent a separate race; scientific description currently in preparation. Monotypic.

Distribution. Highlands and tepuis of S & E Venezuela, Guyana and NC Brazil.

Descriptive notes. 10-11 cm; 7.0 g. Bill straight, blackish above, lower mandible reddish with dark tip. Male has forehead and centre of crown glittering golden green to emerald green; supercilium velvet blackish; rest of crown, auricular area, hindneck and upperparts to rump dark golden green; throat glittering turquoise to golden green, with glittering violet-blue patch on upper throat; belly dark golden green; uppertail-coverts and median rectrices bronze-green to emerald green; outer rectrices blackish-green; undertail-coverts greenish, narrowly edged greyish and rufous. Female is generally lighter in coloration; forehead and crown rarely glittering, lacks black supercilium; white moustachial streak; below, whitish with greenish spots; lacks violet throat patch; small white breast patch; lower belly whitish; rectrices tipped white; undertail-coverts greyish-brown. Immature male has dark green crown with rufous borders, lacks glittering forehead; throat patch reduced or lacking; generally, underparts, especially centres of throat and belly, more greyish-brown.

Habitat. Forest, forest edges, clearings and scrub within the sub-montane zone of *cerros* and *tepuis* of the Pantepui region; mostly at 700–2000 m.

Food and Feeding. Nectar of various plants such as *Tyleria* and insects.

Breeding. Saddle-type nest; clutch size 2. No further information.

Movements. Probably almost sedentary. As the species has not been recorded from the lowlands of southern Venezuela, seasonal movements may be only altitudinal.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species:

present in Tepuis EBA. As an endemic of the Pantepui region, it can be regarded as an insular species with a remarkably scattered distribution, including Duida-Marahuaca and Serranía de la Neblina National Parks (Venezuela/Brazil). Although not recorded in large numbers within the Pantepui region, species seems to be locally abundant. Precise limits of distribution remain uncertain, as data gaps still exist in areas with suitable habitat that are partly unexplored; for example, extent of range in Brazil is unclear.

Bibliography. Barrowclough, Escalante *et al.* (1997), Barrowclough, Lentino & Sweet (1997), Chapman (1931), Chubb (1916), Cory (1918), Forrester (1993), Friedmann (1948), Gerwin & Zink (1989), Grantsau (1988), Mayr & Phelps (1967), Meyer de Schauensee & Phelps (1978), Ruschi (1981–1982, 1986), Sánchez (1995), Sick (1993, 1997), Snyder (1966), Stattersfield *et al.* (1996), Stotz *et al.* (1996), Warren (1966), Willard *et al.* (1991).

190. Black-throated Brilliant

Heliodoxa schreibersii

French: Brillant à gorge noire

Spanish: Brillante Ventrinegro

German: Schwarzkehl-Brillantkolibri

Taxonomy. *Trochilus Schreibersii* Bourcier, 1847, upper Rio Negro, Brazil.

Formerly isolated in monospecific genus *Ionolaima*. Probably closely related to *H. aurescens*. Two subspecies recognized.

Subspecies and Distribution.

H. s. schreibersii (Bourcier, 1847) - SE Colombia, E Ecuador and NE Peru (N of Amazon) to extreme NW Amazonian Brazil (upper R Negro).

H. s. whitelyana (Gould, 1872) - E Peru.

Descriptive notes. 12 cm; male 9.9 g, female 7.1–8.5 g. Bill almost straight and dark in colour. Male has forehead glittering green, crown and rest of upperparts shining green; underparts black with a glittering purple spot on lower throat, bordered below by a narrow band of glittering green; tail very long, deeply forked, steel blue. Female resembles male but has whitish to rufous malar stripe; underparts grey with bronze-green discs and central tail feathers green; tail less deeply forked. Immature resembles female, but malar stripe more deeply coloured. Race *whitelyana* lacks glittering green frontlet and green breast band.

Habitat. Interior of tall humid forest and scrub in tropical and upper tropical zones at elevations between 400 and 1000 m, occasionally up to 1300 m.

Food and Feeding. Forages mainly at heights of about 2–4 m in shady understorey. Feeds on nectar of flowering plants like Ericads. Insects are caught in the air by hawking.

Breeding. Feb–May. Clutch size 2; incubation by female. No further information.

Movements. Sedentary.

Status and Conservation. Not globally threatened. CITES II. Seems to be rather uncommon, but scarcity of reliable data concerning abundance makes overall assessment difficult. Recorded in Manu National Park, Peru.

Bibliography. Best *et al.* (1997), Butler (1979), Cardiff (1983), Fitzpatrick & Willard (1982), Forrester (1993), Gerwin & Zink (1989), Grantsau (1988), Hilty & Brown (1986), Meyer de Schauensee (1982), Parker *et al.* (1982), Ruschi (1981–1982, 1986), Salaman & Mazariegos (1998b), Schulenberg *et al.* (1984), Sick (1993, 1997), Stotz *et al.* (1996), Zimmer (1951a).

191. Pink-throated Brilliant

Heliodoxa gularis

French: Brillant à gorge rose

German: Rotkehl-Brillantkolibri

Spanish: Brillante Gorgirrosado

Taxonomy. *Aphantochroa* ? *gularis* Gould, 1860, Río Napo.

Formerly isolated in monospecific genus *Agapeta*. Probably closely related to *H. branickii*. Monotypic.

Distribution. E Andean foothills of S Colombia, NE Ecuador, NE Peru and extreme NW Brazil.

Descriptive notes. 11–12 cm. Male has almost straight black bill; shining green upperparts with glittering green median stripe on forehead, postocular spot small, white; shining green below, throat with glittering pinkish-red patch, belly grey, undertail-coverts whitish; tail long, forked, bronzy-green. Female similar to male, throat patch smaller.

Habitat. Humid montane forest at 400–900 m, possibly higher.

Food and Feeding. Almost no food plants have been recorded apart from flowering *Psittacanthus* and other Loranthaceae; takes insects.

Breeding. No data available.

Movements. Presumably sedentary.

Status and Conservation. Not globally threatened. CITES II. Currently considered Near-threatened. Restricted-range species: present in Ecuador–Peru East Andes EBA. Generally uncommon. Forest habitat within range is under threat of destruction. Species very poorly known; extensive research required.

Bibliography. Best *et al.* (1997), Butler (1979), Fitzpatrick & Willard (1982), Forrester (1993), Gerwin & Zink (1989), Grantsau (1988), Hilty & Brown (1986), Parker *et al.* (1982), Ruschi (1981–1982, 1982a, 1986), Salaman & Mazariegos (1998b), Sick (1993, 1997), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Taczanowski (1984), Zimmer (1951a).

192. Rufous-webbed Brilliant

Heliodoxa branickii

French: Brillant de Branicki German: Rotflügel-Brillantkolibri Spanish: Brillante Alicanela

Taxonomy. *Lampraster branickii* Taczanowski, 1874, Monterico, Peru.

Formerly isolated in monospecific genus *Lampraster*. Probably closely related to *H. gularis*. Monotypic.

Distribution. SE Peru and probably NW Bolivia.

Descriptive notes. 11–12 cm; 5.1–5.9 g. Bill straight, black; in male, lower mandible partly whitish. Male has glittering crown, changing from green at bill to more bluish towards rear, rest of upperparts shining dark green; central pair of rectrices green, rest dark blue; underparts green with a glittering iridescent rosy patch at centre of throat, undertail-coverts white; the outer web of the outer remiges and the basal parts of the inner ones are a conspicuous cinnamon-rufous, tail slightly forked. Female above similar to male, head with small white streak below eye; throat green with white spot, breast and belly white to buffy inter-spersed with shining green, and with shining green sides and flanks; undertail-coverts white, tail colour similar to male, central rectrices tipped white, tail slightly forked.

Habitat. Forest, forest edge, woodland and also plantations in mainly Andean foothills at elevations of 750–1300 m.

Food and Feeding. Feeds largely on nectar. Proportion of diet consisting of insects has not yet been investigated.

Breeding. Unknown.

Movements. No information available.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species: present in Peruvian East Andean Foothills EBA. The biology of this species has not yet been investigated, in part because its range is very poorly known, so an assessment of abundance or population trends is not possible; however, its acceptance of man-made habitats suggests that it is not under serious threat at present. Occurs between Cuzco and Manu, Peru.

Bibliography. Gerwin & Zink (1989), Meyer de Schauensee (1982), Olrog (1968), Parker *et al.* (1982), Remsen & Traylor (1989), Sagot (1998b), Schulenberg *et al.* (1984), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Zimmer (1930, 1951a).

193. Empress Brilliant

Heliodoxa imperatrix

French: Brillant impératrice German: Rotstern-Brillantkolibri Spanish: Brillante Emperador

Other common names: Empress Eugenie's Hummingbird

Taxonomy. *Eugenia imperatrix* Gould, 1856, Andean forests in the neighbourhood of Quito (probably Pacific slope).

Long segregated in monospecific genus *Eugenia* on the basis of its long, very deeply forked tail. Monotypic.

Distribution. Pacific slope from WC Colombia to NW Ecuador.

Descriptive notes. Male 15–17 cm, 9.3 g; female 12–13.5 cm, 8.3 g. Bill black, feet dusky grey; tail quite variable in length, especially among adult males. Male with frontlet, lores, throat and breast glittering dark green, square patch of glittering pale violet on centre of throat, belly glittering golden green; crown and nape dark green, rest of upperparts dark bronzy-green, central rectrices dark bronze, elongated lateral rectrices black, glossed with bronze. Female is bronzy-green above and on central rectrices, lateral rectrices dull black glossed with bronze; centre of throat and breast greyish, heavily flecked with bronzy-green,

passing to solid bronzy-green laterally and to golden green on belly. Immature male with head, throat and breast dull, dark bronzy-green, centre of throat dusky grey; lores, chin and sides of throat bright buff; golden green of belly duller and bronzier, tail shorter than adult. Immature female has throat buffy like male, green feathers below with buffy fringes and duller than adult.

Habitat. Very wet foothills and lower mountain cloudforest and forest edge, adjacent tall second growth, at 400–2000 m. Both sexes occur in canopy of forest and lower down along edges; only female usually seen in understorey.

Food and Feeding. Regularly visits inflorescences of *Marcgravia* and *Marcgraviastrum*, perching on inflorescence to extract nectar from bracts; hovers to feed from pendent blossoms of epiphytic Ericaceae. Little information on foraging for arthropods; has been observed gleaning and flycatching at lower and middle strata in forest.

Breeding. Jan–Apr (W Colombia). One nest (perhaps incomplete) was a downy cup of balsa floss and cobweb, plastered on top of palm frond 10 m up at forest edge. No further information.

Movements. No information.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species: present in Chocó EBA. Uncommon to locally common in Colombia, its very wet forest habitat still mostly intact, including several protected areas such as Tatamá, Munchique and Farallones de Cali Na-

tional Parks; frequently seen at La Planada Reserve, and also occurs in Rio Nambi Reserve. In Ecuador, regularly recorded in forest around Mindo.

Bibliography. Best *et al.* (1997), Butler (1979), Chapman (1926), Gerwin & Zink (1989), Hilty (1997), Hilty & Brown (1986), Kirwan & Marlow (1996), Meyer de Schauensee (1949, 1982), Olrog (1968), Orejuela *et al.* (1982), Salaman (1996), Salaman & Mazariegos (1998b), Stattersfield *et al.* (1998), Stotz *et al.* (1996).

194. Green-fronted Brilliant

Heliodoxa jacula

French: Brillant fer-de-lance **German:** Grünstirn-Brilliantkolibri **Spanish:** Brillante Coroniverde
Other common names: Green-crowned Brilliant

Taxonomy. *Heliodoxa jacula* Gould, 1850, Santa Fé de Bogotá, Colombia.

Race *jamesoni* often spelt *jamersoni*, due to a typographical error present in original description. Three subspecies recognized.

Subspecies and Distribution.

H. j. henryi Lawrence, 1867 - Costa Rica and W Panama.

H. j. jacula Gould, 1850 - extreme E Panama to N & C Colombia.

H. j. jamesoni (Bourcier, 1851) - SW Colombia and W Ecuador.

Descriptive notes. Male 12-13 cm, 7-9 g; female 10-5-12 cm, 6-8 g; race *henryi*, male 9-4 g, female 8-2 g. Male has forehead, crown, lores, throat and breast glittering dark blue-green, a small metallic violet-blue patch on foreneck, and white postocular spot; rest of upperparts and belly bronzy-green, central rectrices bronzy, rest of deeply-forked tail blue-black. Female lacks glittering areas on head and underparts, has short white malar streak, whitish below very heavily spotted with green; lateral rectrices white-tipped. Immature male dull, dark bronzy-green on crown and underparts with chin and malar area, sometimes entire throat, in striking contrast bright buff; tail shorter and less deeply forked. Immature female has green spotting below duller, throat as young male. Race *henryi* larger, glittering areas of male more brilliant, paler green (little or no bluish tinge), tail of male entirely blue-black, female more extensively white below with bright

Heliconia along streams. Usually perches on inflorescence to feed. Male sometimes defends large clumps of *Marcgravia* or *Heliconia*. Captures arthropods by flycatching and foliage-gleaning.

Breeding. Jul or Aug-Jan (Costa Rica); May-Sept (N & EC Colombia). Nest undescribed.

Movements. In Costa Rica, most of population moves to lower elevations (locally down to 100 m) outside breeding season; no data for other areas.

Status and Conservation. Not globally threatened, CITES II. Common, at least locally, in Costa Rica and Panama (*henryi*), with various protected areas in range, e.g. Tapanti National Park and Monteverde Biological Reserve (Costa Rica). Much less common and more local in Colombia (*jacula*), and in most areas has probably suffered moderate to severe habitat loss due to deforestation; has been recorded in several protected areas, such as Los Katíos National Park and Rio Nambi Reserve. No information available for *jamesoni*.

Bibliography. Anon. (1998a), Best, Checker *et al.* (1996), Best, Heijnen & Williams (1997), Blake (1958), Butler (1979), Chapman (1926), Fjeldså & Krabbe (1990), Fogden (1993), Gerwin & Zink (1989), Hilty & Brown (1986), Pople *et al.* (1997), Ridgely & Gaulin (1980), Ridgely & Gwynne (1989), Ridgway (1911), Rutgers & Norris (1972), Salaman & Mazariegos (1998b), Slud (1964), Stiles (1985b, 1985c, 1995a), Stiles & Skutch (1989), Stotz *et al.* (1996), Wetmore (1968a), Williams & Tobias (1994).

green spotting laterally; male *jamesoni* much duller green on crown, throat and breast; central rectrices glossed with green, tail shorter.

Habitat. Wet subtropical and cloudforest, forest edge, adjacent semi-open and old second growth in mountains and foothills; mostly in middle strata and canopy of forest, female more in understorey. Mostly at 700-2000 m in Costa Rica, 300-1600 m in Colombia.

Food and Feeding. Regularly takes nectar from pipe-shaped bracts of candelabra-like inflorescences of *Marcgravia*; also feeds at other epiphytes (Ericaceae, Gesneriaceae) and shrubs (*Drymonia*, *Cephaelis*), particularly at

Genus *EUGENES* Gould, 1856

195. Magnificent Hummingbird

Eugenes fulgens

French: Colibri de Rivoli **German:** Violettbron-Brilliantkolibri **Spanish:** Colibrí Magnífico
Other common names: Rivoli's Hummingbird; Admirable/Costa Rica/Panama Hummingbird (*spectabilis*)

Taxonomy. *Trochilus fulgens* Swainson, 1827, Temascaltepec, Mexico. Genus sometimes merged into *Heliodoxa*. Race *spectabilis* may be a separate species, on basis of morphological differences and geographical isolation. Populations within southern portion of range of nominate have been separated as race *viridiceps*, but validity highly dubious and no consistent differences are apparent. Two subspecies currently recognized.

Subspecies and Distribution.

E. f. fulgens (Swainson 1827) - SW USA (SE Arizona, SW New Mexico, SW Texas) through most of Mexico to Guatemala, El Salvador, Honduras and NE Nicaragua.

E. f. spectabilis (Lawrence, 1867) - highlands of Costa Rica and W Panama.

Descriptive notes. 11-13 cm, 7.0-7.5 g; race *spectabilis* 12-14 cm, male c. 10 g, female c. 8-5 g. Male has stout, straight, black bill; iridescent purple crown, small white spot behind the eye, upperparts dark green; green gorget, rest of underparts blackish; tail slightly notched, bronze. Female lacks iridescent gorget, bronze coloration on wings and tail, and has paler, greyish underparts. Immature resembles adult female. Race *spectabilis* rather similar, male with blue-green gorget and somewhat paler underparts.

Habitat. Typically at elevations between 1500 and 2500 m. Sometimes above 3000 m in Costa

Rica, although often moves to lower elevation during colder months. In USA and N Mexico found in mixed Sonoran and upper transitional zones; in S Mexico and Central America in upper arid zones with seasonal rainfall to more humid cloudforests. Common in mixed oak-pine forests near riparian areas. Often frequents open areas where food plants grow.

Food and Feeding. Floral nectars from several plant species, including *Crisium*, *Penstemon*, *Agave americana*, *A. parryi*, *Bomarea costaricensis*, *Centropom talamanensis*, *Erythrina corallodendrum*, *Fuchsia splendens* and *Lobelia laxifolia*. Arthropods taken are primarily insects (beetles, flies, bugs Homoptera, Hymenoptera) and spiders.

Breeding. May-Jul in USA (probably true for all migratory populations); in Central America Nov-Jul with peaks during winter flowering seasons. Nest cup-shaped with soft downy interior, exterior covered by lichen or other similar material. Nest usually placed more than 5 m above ground. Clutch size 2; incubation 15-16 days, by female.

Movements. Populations in N and possibly C Mexico migrate N in late autumn or early spring to extreme N Mexico and SW USA. Populations in S Mexico and Central America are sedentary, although altitudinal migrations can occur during cold seasons.

Status and Conservation. Not globally threatened. CITES II. In USA, artificial feeders maintain unusually large populations that exceed available natural food sources. Susceptible to natural or unnatural perturbations such as forest fires because habitat is often restricted to the higher elevations of isolated mountain ranges. In future, habitat destruction could prove to be a significant threat throughout range. In Costa Rica, occurs in several protected areas such as Volcán Poás National Park and Monteverde Biological Reserve.

Bibliography. Baicich & Harrison (1997), Baker & Blake (1962), Baltosser (1986a), Bené (1947), Bent (1940), Binford (1989), Colwell (1973), Cottam & Knappen (1939), DeGraaf & Rappole (1995), Des Granges (1979), Des Granges & Grant (1980), Dickey & van Rossem (1938), Eisenmann (1955), Ely (1960, 1962), Feinsinger (1980), Friedmann *et al.* (1950), Hainsworth & Wolf (1976, 1978), Hainsworth *et al.* (1981), Hejl *et al.* (1995), Howell & Webb (1995a), Johnsgard (1997), Kaufman (1996), Kuban & Neill (1980), Lasiewski & Lasiewski (1967), Lyon (1976), Lyon & Chadek (1971), Marshall (1957), Martínez del Río & Eguarte (1987), Mayr & Short (1970), Miller (1955), Monroe (1968), Navarro *et al.* (1991), Oberholser (1974), Phillips *et al.* (1964), Pimm (1978), Pimm *et al.* (1985), Powers (1996), Remsen, Stiles & Scott (1986), Ridgely & Gwynne (1989), Ridgway (1911), Rising (1965), van Rossem (1939, 1945a), Rutgers & Norris (1972), Schaldach (1963), Short & Phillips (1966), Slud (1964), Spofford (1980), Stiles (1978a), Stiles & Skutch (1989), Stotz *et al.* (1996), Toledo (1974), Urban (1959), Wagner (1957b), Wetmore (1968a), Wolf (1975a), Wolf *et al.* (1976).

Genus *HYLONYMPHA* Gould, 1873

196. Scissor-tailed Hummingbird

Hylonympha macrocerca

French: Colibrí à queue en ciseaux **German:** Grünbrustnymph **Spanish:** Colibrí Tijereta

Taxonomy. *Hylonympha macrocerca* Gould, 1873, no locality = Cerro Azul, Venezuela.

Genus sometimes merged into *Heliodoxa*. Monotypic.

Distribution. Paria Peninsula (NE Venezuela).

Descriptive notes. Male 19 cm (including 9-10 cm tail), 7-7.5 g; female 12-13 cm, 6-5.8 g. Male has long, slightly decurved black bill; glittering violet cap, covering forehead and centre of crown, rest of crown very dark green, almost black; back slightly metallic grass green with a golden hue on the neck;

throat and breast glittering emerald green, rest of underparts duller and darker green, turning blackish on belly, with green discs on flanks; tail long and deeply forked with lateral feathers much longer and broader than the rest, blackish-purple. Female dark shiny green above, lacking the glittering cap; below white spotted with shiny green discs, but centre of breast without spots, forming a white area; belly and undertail-coverts rufous-chestnut; tail forked but much shorter than in male, central pair of rectrices basally green and distally steel blue, lateral tail feathers cinnamon tipped beige.

Habitat. Mainly damp mossy forest with high trees and cloudforest in subtropical and lower subtropical zone. Also occasionally found at forest edge and small clearings. Records range from altitudes of 900 to 1200 m.

Food and Feeding. Nectar is taken mainly from bromeliads in cloudforest; in secondary growth main food plants are *Heliconia aurea* and *Costus*. Females have been recorded establishing feeding territories. Arthropods are either gleaned from bromeliads or caught in the air by hawking.

Breeding. No information.

Movements. Sedentary.

Status and Conservation. CRITICALLY ENDANGERED. CITES II. Restricted-range species: present in Caripe-Paria Region EBA. Generally rare; endemic to Paria Peninsula. Entire range covered by Paria Peninsula National Park since 1978, but is surrounded with intensive cash-crop cultivation belonging to local farmers. Illegal, uncontrolled burning causes severe damage to remaining forest stands. Due to forest destruction large areas are heavily affected by erosion and drying-up of streams. Less disturbed by humans is the area around Macuro in E because of reduced accessibility by road. Another severe threat is the planned gas pipeline, known as "Proyecto Cristóbal Colón", through the national park. Size of remaining population unknown.

Bibliography. Anon. (1989b), Bond *et al.* (1989), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Knox & Walters (1994), Meyer de Schauensee (1982), Meyer de Schauensee & Phelps (1978), Olrog (1968), Paynter (1982), Phelps & Phelps (1948, 1958), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Wege & Long (1995).

Genus *STERNOCLYTA* Gould, 1858

197. Violet-chested Hummingbird

Sternoclyta cyanopectus

French: Colibrí à poitrine violette **German:** Veilchenbrustkolibri **Spanish:** Colibrí Pechiazul

Taxonomy. *Trochilus (Lampornis) cyanopectus* Gould, 1846, Neiguata Plantation, near Camburi Grande, La Guaira, Venezuela.

Genus sometimes merged into *Heliodoxa*. Monotypic.

Distribution. N Venezuela, in Andes of Táchira, Mérida and Lara and coastal mountains E to Miranda.

Descriptive notes. 12-13 cm; male 8.4-9.4 g, female 9.0-10.3 g. Bill slightly curved, black. Male shining grass green above; below with throat glittering emerald green, breast with drop-shaped patch of glittering violet-blue; rest of underparts greyish-buff with golden green discs on flanks; tail bronze, the lateral pair of feathers tipped whitish on inner web. Female above like male; underparts greyish-white with golden green discs, towards centre of belly almost entirely rufescent. Immature resembles female.

Habitat. Humid forest and woodland in lower subtropical zone; also found in old second growth and coffee plantations. Occasionally

down to tropical zone, in rainforest and cloudforest. Altitudinal distribution from sea-level to 1900 m.

Food and Feeding. Usually keeps inside dense vegetation and forages in darkest areas of the forest. Often to be found in damp ravines or *Heliconia* thickets. No further information.

Breeding. Clutch size 2; incubation by female. No further information.

Movements. Sedentary.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species: present in Cordillera de la Costa Central EBA and Cordillera de Mérida EBA. Locally common; seems readily to accept second growth and man-made habitats. Occurs in Henri Pittier National Park.

Bibliography. Brown & Bowers (1985), Collins (1972b), Meyer de Schauensee (1982), Meyer de Schauensee & Phelps (1978), Olrog (1968), Renjifo *et al.* (1997), Rodner (1995), Stattersfield *et al.* (1998), Stotz *et al.* (1996).

Genus *UROCHROA* Gould, 1856

198. White-tailed Hillstar

Urochroa bougueri

French: Colibrí de Bouguer **German:** Blaukehl-Andenkolibri **Spanish:** Colibrí de Bouguer

Taxonomy. *Trochilus Bougueri* Bourcier, 1851, Nanegal, Ecuador.

Formerly considered a close relative of *Oreotrochilus*; behaviour and morphology indicate phylogenetic affinities with *Boissonneaua*. Two subspecies recognized.

Subspecies and Distribution.

U. b. bougueri (Bourcier, 1851) - Pacific slope of Andes of SW Colombia and NW Ecuador.

U. b. leucura Lawrence, 1864 - E slope of E Andes in S Colombia (Nariño), E Ecuador and NE Peru.

Descriptive notes. 13-14 cm (including bill 3 cm); 8.5-9.2 g. Sexes alike. Long, straight, black bill; upperparts coppery green, rufous cinnamon malar streak; throat and breast iridescent blue, belly dull grey; central and outermost rectrices black, rest white with dusky grey edges. Immature similar to adult but head feathers with buff fringes. Race *leucura* has bronzy-green upperparts, lacks rufous malar streak; central tail feathers bronzy, others white, dusky grey on outer web.

Habitat. Montane forest, forest edge and secondary growth, especially near streams, at 1600-2800 m, most numerous around 1800 m;

occasionally found on shrubby slopes and at much lower elevations, for example on Pacific slope in SW Colombia. Forages inside forest, usually solitarily, from lowest to middle strata.

Food and Feeding. Nectar of flowering *Inga* trees, *Bomarea*, *Psammisia* and *Cavendishia*. Insects are caught above streams or in forest openings by hawking. Male establishes feeding territories at nectar-rich flower stands, sometimes as low as 1-2 m.

Breeding. Dec-Mar in SW Colombia. Cup-shaped nest of moss and lichen is built on vertical, medium-sized branch of tall tree, often 8-12 m above ground. Clutch size 2; incubation 16-18 days, by female; chick black with sparse buff dorsal down; fledging period 23-25 days.

Movements. Sedentary, with some seasonal altitudinal dispersal, especially on Pacific side of Colombia.

Status and Conservation. Not globally threatened. CITES II. Common in cloudforests and along streams. Accepts man-made habitats, such as pastures, so long as some forested patches remain. Regularly recorded in La Planada Reserve (S Colombia).

Bibliography. Best *et al.* (1997), Butler (1979), Fjeldså & Krabbe (1990), Hilty & Brown (1986), Kirwan & Marlow (1996), Meyer de Schauensee (1982), Olog (1968), Parker *et al.* (1982), Renjifo *et al.* (1997), Salaman & Mazariegos (1998b), Stotz *et al.* (1996).

Genus *BOISSONNEAU* Reichenbach, 1854

199. Buff-tailed Coronet

Boissonneaua flavescens

French: Colibri flavescens **German:** Fahlschwanzkolibri **Spanish:** Colibrí Colihabano

Taxonomy. *Trochilus flavescens* Loddiges, 1832, Popayán, Colombia.

Specimens at the south end of the range of nominate are similar in colour to *tinochlora*, but the subspecific distinction is still evident in the general coloration and the pattern of the tail-feather tips. Two subspecies recognized.

Subspecies and Distribution.

B. f. flavescens (Loddiges, 1832) - Andes of NW Venezuela (Mérida) and Colombia (all three ranges).

B. f. tinochlora Oberholser, 1902 - SW Colombia and W Andean slope of Ecuador.

Descriptive notes. 11-12 cm; 8.0-8.6 g. Bill straight, black. Male shining green above; throat and breast are shining green, remainder of underparts buff strongly marked with green discs, underwing-coverts cinnamon and conspicuous in flight; central pair of feathers in the slightly forked tail bronzy, rest buff with bronzy edges and tips; rather small leg puffs white. Sexes similar, but female has more buffy underparts, shorter wings and tail and narrower bronzy edges and tips of lateral rectrices. Immature like female but with brownish edges to rump feathers. In *tinochlora* the buff parts of plumage have a distinctive cinnamon hue,

bronzy tips to tail feathers are broader than in nominate; in female and immature, tail-feather tips are only slightly narrower than in adult male.

Habitat. Throughout its quite extensive range inhabits humid and wet montane forest, cloudforest and dwarf forest and forest borders, but also open and more shrubby areas in upper subtropical and lower temperate zones, at elevations between 2000 and 3500 m.

Food and Feeding. Usually feeds in middle strata but also occasionally found in canopy. Main food plants are *Cavendishia*, *Palicourea*, *Disterigma* and *Huilaia*. While feeding, typically clings to flowers rather than hovering. Frequently seen hawking for insects in long sallies from high perches, but sometimes also clings to tree trunks when gleaning insects. Has also been observed feeding at sap trees at holes made by woodpeckers. Territorial and pugnacious.

Breeding. Apr-Aug (Colombia) and Nov-Mar. Nest is cup-shaped, built mainly of moss and lichen; usually attached to branch 3-10 m above ground. Clutch size 2; incubation by female. First breeds in second year.

Movements. Sedentary.

Status and Conservation. Not globally threatened. CITES II. Rare to locally fairly common. Frequently seen along old road to Mindo (W Ecuador), with densities of at least 1-2 pairs/km². Present in La Planada Reserve (S Colombia).

Bibliography. Best *et al.* (1997), Brown & Bowers (1985), Butler (1979), Chapman (1917, 1926), Fjeldså & Krabbe (1990), Hilty & Brown (1986), Kattan & Murcia (1985), Kirwan & Marlow (1996), Meyer de Schauensee (1949, 1982), Meyer de Schauensee & Phelps (1978), Miller (1963), Olog (1968), Ridgely & Gaultin (1980), Salaman & Mazariegos (1998b), Snow & Snow (1980), Stotz *et al.* (1996), Vélez & Velázquez (1998).

200. Chestnut-breasted Coronet

Boissonneaua matthewsii

French: Colibri de Matthews **German:** Rotbauchkolibri **Spanish:** Colibrí Pechirrojo

Taxonomy. *Trochilus Matthewsii* Bourcier, 1847, Peru.

Despite extensive range, species shows no marked geographical variation. Monotypic.

Distribution. Andes of extreme SE Colombia, Ecuador and Peru (on W slope S to Cajamarca, on E slope S to Cuzco).

Descriptive notes. 12 cm; 7.0-7.7 g. Sexes similar. Bill straight, thickish and black. Male shining metallic green above and chestnut-rufous below, with throat more or less spotted with green discs; tail only slightly forked, the central pair of rectrices bronze-green and remainder rufous with bronze-green edges and tips; sparsely developed tibial tufts light cinnamon in colour and rather inconspicuous. Immature with more extensive green areas on underparts, upperparts with cinnamon feather edges, especially on rump.

Habitat. Inhabits humid pre-montane forest in subtropical areas at elevations of 1200-

2600 m, occasionally up to 3000 m in Peru. Usually found inside forest, less often at edges or in more open vegetation.

Food and Feeding. Establishes territories around clusters of flowers and can be seen foraging for nectar mainly at canopy level. Often clings to flowers while feeding. Occasionally several individuals may gather at flowering trees. Additionally, feeds on insects obtained by hawking from high perches. Territorial and highly pugnacious like all members of genus. No further information.

Breeding. No data concerning season. The nest is cup-shaped and consists mainly of moss and lichen. Clutch size 2; incubation by female. First breeding in second year. No further information.

Movements. Sedentary.

Status and Conservation. Not globally threatened. CITES II. Fairly common. Range of present species coincides with the distribution of humid pre-montane forest; this is evident in W Peru, where species is restricted to the northern part of the Andes. Only a few records from Colombia. Has been recorded in North Podocarpus National Park (Ecuador).

Bibliography. Best *et al.* (1997), Brown & Bowers (1985), Butler (1979), Davies *et al.* (1994), Fjeldså & Krabbe (1990), Hilty & Brown (1986), Meyer de Schauensee (1982), Mobbs (1972b), Olog (1968), Parker *et al.* (1982), Renjifo *et al.* (1997), Salaman & Mazariegos (1998b), Stotz *et al.* (1996), Williams & Tobias (1994), Wittmann (1986), Zimmer (1951b).

201. Velvet-purple Coronet

Boissonneaua jardini

French: Colibri de Jardine **German:** Hyazinthkolibri **Spanish:** Colibrí Sietecolores
Other common names: Jardine's Hummingbird

Taxonomy. *Trochilus Jardini* Bourcier, 1851, Nanegal, Ecuador.

Monotypic.

Distribution. Pacific slope of W Andes in SW Colombia (Cerro Tatamá to Nariño) and NW Ecuador.

Descriptive notes. 11-12 cm; 8.0-8.5 g. Bill straight, black. Male shining bluish-green above with head and throat velvety black; crown, breast and belly glittering purplish-blue; underwing-coverts cinnamon and conspicuous in flight; tail slightly forked, central feathers black, the rest white with black tips and edges; small leg puffs also white. Female similar but duller in coloration, with feathers of breast and belly fringed buff; wings are shorter and tail less deeply forked than in male. Immature like female.

Habitat. Prefers wet mossy forests and forest borders in tropical and subtropical zones, but

can also be found at shrubby clearings in Pacific lowlands and on lower slopes. Records range from 350 to 2200 m, commonest above 1200 m.

Food and Feeding. Territorial, usually seen feeding at flowers from lower strata to tree tops. Insects are caught in the air by hawking. No further information.

Breeding. Jan-Mar. Nest cup-shaped, made of moss and lichen, placed on a horizontal branch or thin fork. Clutch size 2; incubation by female. First breeding in second year. No further information.

Movements. Sedentary, but seasonal altitudinal dispersal known in Colombia.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species: present in Chocó EBA. Uncommon and very local, most frequently found in the area around the type locality in NW Ecuador. Comparatively few Colombian records, mostly from S Nariño, where regularly recorded in protected areas, notably La Planada and Río Nambi Reserves.

Bibliography. Best *et al.* (1997), Brown & Bowers (1985), Butler (1979), Hilty & Brown (1986), Kirwan & Marlow (1996), Meyer de Schauensee (1949, 1982), Mobbs (1972b), Olog (1968), Ruschi (1961d, 1973b), Rutgers & Norris (1972), Salaman (1996), Salaman & Mazariegos (1998b), Stattersfield *et al.* (1998), Stotz *et al.* (1996).

Genus *AGLAEACTIS* Gould, 1848

202. Shining Sunbeam

Aglaeactis cupripennis

French: Colibrí étincelant **German:** Rostrotter Andenkolibri **Spanish:** Colibrí Cobrizo
Other common names: Copper-winged Hummingbird

Taxonomy. *Trochilus cupripennis* Bourcier, 1843, Colombia.

Forms a superspecies with *A. castelnaudii* and possibly with *A. aliciae*. Although the morphological variation in the genus might suggest past gene flow between present species and *A. castelnaudii*, they are nowadays reproductively isolated in the zone of overlap. Occasionally considered to include *A. aliciae* as a race. Otherwise, up to six races of present species have been accepted at various times, with *aequatorialis* (N & C Ecuador), *parvulus* (S Ecuador, N Peru), *cajabambae* and *ruficauda* (both of NC Peru) replacing each other southwards through Ecuador and Peru, but morphometric and plumage characters strongly indicate clinal variation, and all four now subsumed into nominate. Two subspecies currently recognized.

Subspecies and Distribution.

A. c. cupripennis (Bourcier, 1843) - all three Andean ranges of Colombia, Ecuador and Peru (S to Huánuco and Lima).

A. c. caumatnotus Gould, 1848 - C & SC Peru (Junín, Apurímac, Cuzco).

Descriptive notes. 12-13 cm; male 7.6-8.1 g, female 6.9-7.5 g. Male has short, straight, black bill; crown and mantle dark brown, lower back to rump iridescent lilac-gold shading to shining silver-green on uppertail-coverts; throat rufous with dusky grey dots, light buff patches on breast, rufous brown on belly; rectrices range from dark brown to rufous, and are usually edged bronze. Female similar to male, often with iridescent lilac-golden and green on back reduced, sometimes absent. Immature light brown, lacks iridescent colours on back. Within nominate, clinal variation towards south shows increase in brightness of underparts.

darkness of crown, and amount of rufous in tail. Race *caumatnotus* iridescent amethyst on rump, uppertail-coverts purplish-amethyst.

Habitat. Sub-*páramo* to open *páramo* with scattered shrubs and trees, upper cloudforest, semi-arid montane ridges with interspersed trees at 2500-4300 m. Forages from lowest strata to tree tops.

Food and Feeding. Nectar of flowering terrestrial bromeliads, vines and trees, such as *Puya*, *Bomarea*, *Fuchsia*, *Centropogon*, *Embothrium*, *Mutisia*, *Passiflora* and *Tristerix*. Insects are caught in the air by hawking. Male defends feeding territories at nectar-rich flowering stands.

Breeding. All year round. Mar-Sept (Colombia), Feb-Apr (Ecuador), Nov, Apr (Peru). Cup-shaped compact nest of moss and cobweb, sometimes decorated with pieces of bark, leaf and lichen on outer wall, lined with soft white or brown plant fibre; built on branch or attached to epiphyte near tree tops, 4-10 m above the ground, occasionally up to 15 m. Clutch size 2; incubation 16-18 days, by female; chick black with some buff-coloured dorsal down; fledging at 24-27 days. First breeding in second year.

Movements. Altitudinal migrant in most parts of Colombia, descending seasonally to lower elevations.

Status and Conservation. Not globally threatened. CITES II. Generally fairly common; accepts a wide range of high Andean habitats including farmland with scattered stands of trees. Occurs in several protected areas throughout its range such as Puracé National Park (Colombia), and Las Cajas National Recreation Area and North Podocarpus National Park (Ecuador).

Bibliography. Berlepsch (1898), Best *et al.* (1997), Bloch *et al.* (1991), Butler (1979), Carriker (1933), Fjeldså (1995), Fjeldså & Krabbe (1990), Hilty & Brown (1986), Koepcke (1954, 1957, 1958, 1961, 1970), Krüger *et al.* (1982), Moynihan (1979), Parker & O'Neill (1980), Parker *et al.* (1982), Peters & Griswold (1943), Ruschi (1961c), Sanft (1970), Schuchmann (1985a), Schuchmann & Abersfelder (1986), Schuchmann *et al.* (1983), Stotz *et al.* (1996), Wiedenfeld (1985), Williams & Tobias (1994), Zimmer (1951b).

203. White-tufted Sunbeam

Aglaeactis castelnaudii

French: Colibri de Castelneau **German:** Rotbrust-Andenkoliбри **Spanish:** Colibri Condecorado

Taxonomy. *Trochilus Castelnaudii* Bourcier and Mulsant, 1848, mountains near Cuzco, Peru. Forms a superspecies with *A. cupripennis* and possibly with *A. aliciae*. May be sister-species of *A. pamela*. Although the morphological variation in the genus might suggest past gene flow between *A. cupripennis* and present species, they are nowadays reproductively isolated in the zone of overlap. Two subspecies recognized.

Subspecies and Distribution.

A. c. regalis Zimmer, 1951 - Andes of Huánuco, Pasco and Junín (C Peru).

A. c. castelnaudii Bourcier & Mulsant, 1848 - Andes of Huancavelica, Ayacucho, Apurímac and Cuzco (SC Peru).

Descriptive notes. 12 cm; 7.8-5 g. Bill straight, black. Immediate impression is fuscous with tawny tail, the shining back is displayed during hovering. Male above fuscous black with strong magenta reflection on rump and lower back; below dull brown with blackish upper throat and pectoral band and white feather tuft on central breast; tail forked. Female with less iridescent back and less fork in tail. Immature more uniform brown with no iridescent feathers. Race *regalis* has shorter bill; generally more rufous brown, with rufous tail.

Habitat. Inhabits patches of evergreen montane forest in slightly drier zones and often at much greater altitudes than *A. cupripennis*. Particularly common in *Escallonia* and *Polylepis* forests with abundant flowering vines. Subordinate to *A. cupripennis*, keeping low in the vegetation where the other species is present; at 3500-4300 m, rarely to 4600 m.

Food and Feeding. Takes nectar from flowers of *Barnadesia*, *Berberis*, *Brachyotum*, *Centropogon*, *Labiatae*, *Lupinus*, *Salpichroa* and *Siphocampylus*. Always feeds clinging to the flowers. Also takes insects in the air.

Breeding. Not known.

Movements. Remains in the same area during short periods of heavy snow. However, seasonal habitat shifts may take place in the dry season.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species: present in Peruvian High Andes EBA. Common at very few sites. Although its habitat has been destroyed in much of Huancavelica and Ayacucho, and in Cuzco species has become restricted to Cordilleras Vilcanota and Vilcabamba, many suitable patches of habitat remain in Apurímac. Occurs in the small Machu Picchu Historical Sanctuary.

Bibliography. Fjeldså (1991, 1992, 1995), Fjeldså & Kessler (1996), Fjeldså & Krabbe (1990), Meyer de Schauensee (1982), Morrison (1948), Parker *et al.* (1982), Schuchmann (1985a), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Zimmer (1930, 1951b).

204. Purple-backed Sunbeam

Aglaeactis aliciae

French: Colibri d'Alice **German:** Weißbrust-Andenkoliбри **Spanish:** Colibri de Alicia

Taxonomy. *Aglaeactis aliciae* Salvin, 1896, Succa, 10,000 feet [c. 3000 m], La Libertad, north Peru. May belong to the superspecies of *A. cupripennis* and *A. castelnaudii*. Taxonomic status still unresolved: some authors consider it a race of *A. cupripennis*, since immature birds have a buff-spotted chin and throat turning pure white after the first moult; otherwise, it resembles race *caumatnotus* of that species. Monotypic.

Distribution. E slope of W Andes at Succa, La Libertad (N Peru).

Descriptive notes. 12-13 cm; 7.3-8.3 g. Male has short, straight, black bill; head and mantle earth brown, lower back and rump iridescent amethyst becoming golden green on uppertail-coverts; lores, chin, throat, central breast and pectoral tufts white, otherwise darkish brown; rectrices bronze, white at base. Female similar to male but iridescent parts on back reduced to uppertail-coverts or completely lacking. Immature similar to adult female but with buffy spots on lores, chin, throat and central belly; throat may even be completely buff-coloured; head feathers fringed buff.

Habitat. Semi-open Andean slopes with *Alnus*

trees and shrubs at 3000-3200 m.

Food and Feeding. Nectar of flowering mistletoe *Tristerix longibracteatum* and small insects. Food spectrum and foraging behaviour are little known.

Breeding. No data available. Season may be around Sept-Aug; males with slightly enlarged testes recorded in Jun.

Movements. Sedentary.

Status and Conservation. VULNERABLE. CITES II. Restricted-range species: present in Marañón Valley EBA. Classified as a threatened species on the basis of restricted range and limited information available regarding current condition of habitat. May tolerate some degree of habitat change, like congeners.

Bibliography. Carriker (1933), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Fjeldså & Krabbe (1990), Olrog (1968), Parker *et al.* (1982), Schuchmann (1985a), Stattersfield *et al.* (1998), Stephens & Traylor (1983), Stotz *et al.* (1996), Wege & Long (1995), Zimmer (1951b).

205. Black-hooded Sunbeam

Aglaeactis pamela

French: Colibri paméla **German:** Schwarzbauch-Andenkoliбри **Spanish:** Colibri Negroito

Taxonomy. *Ornismya Pamela* d'Orbigny, 1838, Yungas of Bolivia.

May be sister-species of *A. castelnaudii*. Monotypic.

Distribution. Cordillera Real of Bolivia.

Descriptive notes. 13 cm; 7.8-5 g. Bill short, straight, black. Generally black with contrasting white pectoral tuft. Male has shining bluish-malachite rump (sometimes spreading over most of the back); tail slightly forked, rufous. Female duller black than male, less iridescent on back and with tail less forked. Immature resembles adult female.

Habitat. Most common in tree-line shrubbery in the transition zone between humid slopes and montane basins, especially in rather open areas with some *Barnadesia* and *Polylepis* patches, at 3000-3500 m or rarely down to 1800 m. Also in humid upper montane forest.

Food and Feeding. Forages for nectar at *Barnadesia* and *Berberis* bushes, *Puya* and *Centropogon*. Always feeds clinging to the flowers. Also takes insects.

Breeding. Probably Sept-Mar, but no nests recorded. Evidently first breeds in second year.

Movements. Some records at low elevations suggest that there is some local altitudinal migration.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species: present in Bolivian and Peruvian Upper Yungas EBA. Common in Yungas of La Paz and Cochabamba; also elsewhere, even in places with considerable man-induced habitat fragmentation. Protected in the Carrasco-Ichilo and Amoro National Parks.

Bibliography. Bond & Meyer de Schauensee (1943), Fjeldså (1992, 1995), Fjeldså & Kessler (1996), Fjeldså & Krabbe (1990), Meyer de Schauensee (1982), Niethammer (1953), Olrog (1968), Remsen & Traylor (1989), Rentinck (1981), Schuchmann (1985a), Stattersfield *et al.* (1998), Stotz *et al.* (1996).

Genus *OREOTROCHILUS* Gould, 1847

206. Andean Hillstar

Oreotrochilus estella

French: Colibri estelle **German:** Estella-Andenkolibri **Spanish:** Colibrí Puneño
Other common names: Stripe-bellied Hillstar (*estella*); Bolivian Hillstar (*bolivianus*)

Taxonomy. *Trochilus Estella* d'Orbigny and Lafresnaye, 1838, La Paz and Potosí, Bolivia. Forms a superspecies with *O. chimborazo*, *O. stolzmanni* and *O. leucopleurus*, and all four have been considered conspecific, but separated largely on morphological grounds; the last-mentioned overlaps slightly with present species, and some hybridization reported, but despite this it is the form least frequently lumped into present species; *O. stolzmanni* frequently considered a race of present species. Two subspecies recognized.

Subspecies and Distribution.

O. e. estella (d'Orbigny & Lafresnaye, 1838) - Andes of SW Peru, W Bolivia, N Chile and NW Argentina.

O. e. bolivianus Boucard, 1893 - Andes of C Bolivia (Cochabamba).

Descriptive notes. 13-15 cm; male c. 8-8 g, female c. 8-0 g. Male has medium-sized, slightly decurved black bill; drab brown above; very shiny emerald green gorget with black border, mostly white below with rufous median line on belly; tail forked, white, central feather pair and outer edge and tip of lateral feathers bronzy-black. Female drabber below, with finely speckled throat, tail greenish-black, outer 3-4 feathers with white inner webs at base and tip. Immature more greyish, with yellow base to mandible, immature male with dark glaucous gorget. Male of race *bolivianus* has median line on belly chestnut spotted black.

Habitat. Inhabits *puna* grasslands, where most commonly found around rocky outcrops and in other places with a variety of flowering shrubs. Often particularly common near houses, in stands of *Puya raimondii* and at edges of *Polylepis* woodlands. In the breeding season the sexes segregate to different habitats, where females hold territories in bushy gorges near rocks, while males are territorial and wander through the open grassland. Roosts (in torpor) clinging to vertical rock surface, selecting well protected sites in caves and deep crevices during the southern winter. Occurs from 2400 m to 5000 m, commonest at 3500-4500 m.

Food and Feeding. Feeds while perched, taking nectar from the orange flowers of *Chuquiraga spinosa* shrubs and from low cushion cacti. Also visits other flowering shrubs such as *Barnadesia*, *Berberis*, *Buddleia*, *Malva* and *Ribes*, *Bomarea* vines, *Puya* and flowering *Eucalyptus* trees. In the rainy season visits a variety of mainly red flowers more or less hidden in the grassland, such as *Cajophora*, *Centropogon*, or cushion-like cacti. Gleans arthropods from vegetation and sometimes catches insects high up in the air.

Breeding. Sept-Dec. Females hold territories in bushy gorges with rocks, several females nesting semi-colonially in particularly suitable places. Occasionally places nest under the "skirt" of a *Puya raimondii*. Large woolly cup-nest is glued to rock surface. Clutch size 2; incubation 20 days; fledging period 38 days though shorter in warm places; possibly sometimes lays second clutch. Nesting success 68%, which is exceptionally high for a hummingbird. Probably first breeds in second year.

Movements. During the breeding season males move around in the grassland. Remains in the uplands during short periods of snow, but may disperse to adjacent warmer valleys during the southern winter.

Status and Conservation. Not globally threatened, CITES II. One of the commonest *puna* birds, except in areas where traditional burning and overgrazing have severely reduced plant diversity. Protected in several areas, notably Calipuy National Sanctuary, Huascarán National Park and Salinas y Aguada Blanca National Reserves (Peru), Ulla-Ulla and Sajama National Parks (Bolivia) and Lauca National Park (Chile).

Bibliography. Araya & Chester (1993), Bond & Meyer de Schauensee (1943), Canevari *et al.* (1991), Carpenter (1974, 1976), Dorst (1956, 1962), Fjeldså (1983, 1992), Fjeldså & Kessler (1996), Fjeldså & Krabbe (1990), Fjeldså & Mayer (1996), Flores & Capriles (1998), Johnson (1967, 1972), Koepeke (1970), Langner (1973), Niethammer (1953), Parker *et al.* (1982), Pearson (1953), de la Peña (1994), Remsen & Traylor (1989), Rocha & Peñaranda (1995), Rocha & Quiroga (1996), Rutgers & Norris (1972), Stotz *et al.* (1996), Vuilleumier & Simberloff (1980), Zimmer (1930, 1951a).

207. Ecuadorian Hillstar

Oreotrochilus chimborazo

French: Colibri du Chimborazo **Spanish:** Colibrí del Chimborazo
German: Ecuador-Andenkolibri
Other common names: Violet-hooded Hillstar; Chimborazo Hillstar (*chimborazo*)

Taxonomy. *Trochilus Chimborazo* DeLattre and Bourcier, 1846, Mount Chimborazo, Ecuador. Forms a superspecies with *O. estella*, *O. stolzmanni* and *O. leucopleurus*, and all four have been considered conspecific, but separated largely on morphological grounds. Race *soederstroemi* is sometimes thought to be an intergrade of *jamesonii* and nominate, but it is apparently isolated geographically from both of them. Three subspecies currently recognized.

Subspecies and Distribution.

O. c. jamesonii Jardine, 1849 - mountains of extreme S Colombia and N Ecuador (Cotacachi, Pichincha, Iliniza, Antisana, Cotopaxi).

O. c. soederstroemi Lönnberg & Rendahl, 1922 - C Ecuador (Mt Quilotoa).

O. c. chimborazo (DeLattre & Bourcier, 1846) - C Ecuador (Mt Chimborazo, possibly also Azuay).

Descriptive notes. 13 cm; 7-8-8-1 g. Bill black, slightly curved. Male upperparts dark olive green; entire head and upper throat covered by a glittering purplish-blue hood, lower throat glittering green, bordered below by a narrow black breast band; rest of underparts white with dark undertail-coverts and thin dark line down centre of belly; tail only slightly forked, central tail feathers dark, remainder white with dark tips and edges, the outermost pair largely dark and with the outer web narrower. Female pale bronze-green above, tail dark shining green, less forked than in male, the outer pair of rectrices white at base and tip; throat whitish, densely speckled with brown discs, rest of underparts pale greyish. Immature resembles female, but juvenile male can be recognized by pale region across upper breast; immature male has dark glaucous hood. Northernmost race *jamesonii* has an entirely violet hood, and outer rectrices show less white than in nominate; race *soederstroemi* has only a few green feathers at lower border of throat patch.

Habitat. Inhabits highest vegetated zones up to snow-line at elevations of 3500-5200 m. This high-altitude habitat is split into a series of "islands" along a number of isolated volcanic mountains. The species is typically found near upper border of *páramo* zone, mainly in rather arid *puna*-like grassland habitats, sometimes with some stunted trees and shrubs, but also on more humid *páramo* and on rocky slopes. Especially near secluded ravines, but also uses man-made habitats resulting from frequent burning of vegetation and pastures. At night roosts in caves and crevices, mostly in a torpid state to cope with low night temperatures. Also uses caves for shelter during the hailstorms frequent in this high-altitude habitat.

Food and Feeding. Territorial and notably aggressive. Often perches conspicuously on top of a shrub for long periods, but uses lower and more protected perches in windy weather. While feeding, typically clings to flowers with its comparatively large feet rather than hovering. The most important nectar source is *Chuquiraga insignis*, a composite scrub with orange flowers. Among other food plants recorded are Malvaceae and *Puya*. This diet is supplemented by a considerable number of insects, obtained mainly by hawking but also by gleaning from leaves and cliff surface.

Breeding. Mainly Oct-Feb (*jamesonii*), but nests found throughout the year. The nest consists of moss, roots, dry grass, feathers, rabbit fur and plant down and is very large in order to protect against severe weather and cold, especially at night; typically situated in cave, gully, or wall of steep ravine, usually below an overhang for additional protection; where such places are scarce several nests often found in close vicinity. Nest may also be built in a *Polylepis* tree or suspended from small ferns. Shape varies depending on substrate to which nest is attached: nest-sites usually 0-6-6 m above ground. Clutch size 2; incubation by female; incubation and fledging periods very long; exact figures lacking, but probably as in *O. estella*. Chick black and naked; young birds continue to use the nest for some time after they can fly.

Movements. Some altitudinal movements have been observed, possibly as an adaptation to the harsh highland climate.

Status and Conservation. Not globally threatened, CITES II. Fairly common; typical habitat is not subject to a high level of degradation, and species also accepts man-made environments. Occurs in several protected areas, e.g. Cotopaxi National Park and Las Cajas National Recreation Area (Ecuador).

Bibliography. Berlioz (1933b, 1971b, 1974), Berlioz & Jouanin (1942), Best *et al.* (1997), Butler (1979), Chapman (1926), Fjeldså & Krabbe (1990), French & Hodges (1959), Hilty (1994), Meyer de Schauensee (1982), Olrog (1968), Ortiz & Bleiweiss (1982), Ortiz & Carrión (1991), Rothschild (1927), Ruschi (1949b), Salaman & Gandy (1994), Salaman & Mazariegos (1998b), Smith (1969), Stotz *et al.* (1996), Vuilleumier (1976), Woods *et al.* (1998), Zimmer (1951a).

208. Green-headed Hillstar

Oreotrochilus stolzmanni

French: Colibri de Stolzmann **German:** Grünkopf-Andenkolibri **Spanish:** Colibrí de Stolzmann
Other common names: Stolzmann's Hillstar

Taxonomy. *Oreotrochilus stolzmanni* Salvin, 1895, Huamachuco and near Cajamarca, Peru. Forms a superspecies with *O. estella*, *O. chimborazo* and *O. leucopleurus*, and all four have been considered conspecific, but separated largely on morphological grounds; present species frequently lumped into *O. estella*. Monotypic.

Distribution. Andes of N & C Peru (Cajamarca, Huánuco); recently reported from S Ecuador.

Descriptive notes. 13-14 cm; 7-9-8-4 g. Male has medium-sized, slightly decurved black bill; upperparts greenish with bronzy sheen; throat emerald green, black line separating throat from white underparts; fine black line along central belly; tail whitish, central rectrices dull bronzy. Female similar to male, below pale white, greyish spots on throat, tail greenish-black, outer rectrices with white inner webs at base and tip. Immature similar to adult female.

Habitat. Rocky alpine grassland of the Altiplano (*puna*) with scattered stands of *Puya* and *Polylepis* forest, at 3600-4200 m. Forages below 3 m; usually perches, rather exposed,

on *Puya* inflorescences or rocks, sometimes on the ground, in open terrain. At night, birds seek shelter in rocky cavities or in caves, where several birds often roost closely together, clinging to the rocky wall.

Food and Feeding. Primarily nectar and pollen of flowering *Chuquiraga*, *Cajophora*, *Puya* and cacti. Usually perches on or clings to flowers while feeding. Insects are caught in the air by hawking. Males and to a lesser extent females defend feeding territories against intruders.

Breeding. Feb-Jun, sometimes up to Aug. Bulky cup-shaped nest of moss and soft plant fibres is built in rock cavities close under overhangs, roofs of houses, or even inside open buildings like

barns. Clutch size 2; incubation 19-21 days, by female; chick darkish with two dorsal rows of dull grey down; fledging period 36-40 days. First breeding in second year.

Movements. Mostly sedentary, with seasonal local wandering to lower elevations.

Status and Conservation. Not globally threatened, CITES II. Locally common, especially on alpine meadows with mats of *Chusquea*. The habitat of this species being mostly unsuitable for agricultural purposes, it would appear that no immediate conservation measures are required.

Bibliography. Berlioz & Jouanin (1942), Best *et al.* (1997), Fjeldså & Krabbe (1990), Olrog (1968), Rousseau-Decelle (1942), Sanft (1970), Simon & Hellmayr (1908), Zimmer (1951a).

209. White-sided Hillstar

Oreotrochilus leucopleurus

French: Colibri à flancs blancs

Spanish: Colibrí Cordillerano

German: Weißflanken-Andenkolibri

Taxonomy. *Oreotrochilus leucopleurus* Gould, 1847, Chilean Cordilleras.

Forms a superspecies with *O. estella*, *O. chimborazo* and *O. stolzmanni*, and all four have been considered conspecific, but separated largely on morphological grounds; *O. estella* overlaps slightly with present species, and some hybridization reported, in spite of which present species is the form least frequently lumped into *O. estella*. Monotypic.

Distribution. S Bolivia (Tarija) S through Andes to SC Chile (Bío-Bío) and S Argentina (WC Santa Cruz).

Descriptive notes. 13-15 cm (bill 2 cm), 7.9-8.4. Bill slightly curved, black. Resembles *O. estella*, but male has broad blue-black median stripe below, and tail more rounded because of shorter, narrower and inwards-curving outer rectrices, which are white only at base. Female and juvenile have narrow outer rectrices with complete dark transverse bar.

Habitat. Puna with dwarf bushes, columnar cacti and Puya, at 1200-4000 m, sometimes even to the snow-line.

Food and Feeding. Probably as *O. estella*; feeds on nectar from flowers of *Barnadesia*, *Berberis* and *Chusquea* bushes, larger Puya

species and probably some herbs.

Breeding. Nov-Dec. Large cup-shaped nest is glued to a vertical rock-face, usually in a well protected site. Clutch size 2. No further information.

Movements. During the southern winter normally leaves its Chilean territory, but a record in Jul at 600 m in N Chile demonstrates altitudinal displacements within Chile.

Status and Conservation. Not globally threatened, CITES II. Generally common; limits of range in Argentina recently found to extend much further S than previously thought. Large tracts of core habitat are under slight pressure from man, including several protected areas of considerable extent, such as Laguna de Los Pozuelos, Olaroz-Cauchari, Laguna Brava, San Guillermo, Volcán Tupungato and Lanín (Argentina); also present in Cerro La Campana National Park (Chile).

Bibliography. Araya & Chester (1993), Bond & Meyer de Schauensee (1943), Canevari *et al.* (1991), Carpenter (1976), Fjeldså & Krabbe (1990), Johnson (1967), Marín *et al.* (1989), Narosky & Yzurieta (1993), Navas (1968), Olrog (1968, 1984), de la Peña (1994), Remsen & Traylor (1989), Stotz *et al.* (1996), Wetmore (1926).

210. Black-breasted Hillstar

Oreotrochilus melanogaster

French: Colibri à plastron noir

Spanish: Colibrí Pechinegro

German: Schwarzbrust-Andenkolibri

Taxonomy. *Oreotrochilus melanogaster* Gould, 1847, no locality = Maraynioc, Junín, Peru.

On present knowledge, it is not fully clear whether this is a melanistic representative of the *O. estella* superspecies or an independent species. Monotypic.

Distribution. C Peru, in Junín and Huancavelica and locally into adjacent mountains of Ancash, Lima, Pasco and Ayacucho.

Descriptive notes. 13-14 cm; c. 8.4 g. Bill slightly decurved, black. Male darker and more bronzed above than *O. estella*; gorget shining emerald green, rest of underparts black, flanks drab greyish-brown; tail slightly forked, blue-black. Female like that of *O. estella* but lacks white at base of tail feathers.

Habitat. Puna slopes, usually with a high density of *Chusquea spinosa* bushes and low cushion cacti, and with some rocky areas usually with rich herbaceous vegetation in sheltered recesses. Often in gardens, and also recorded in a stand of *Puya raimondii* at 3500-4400 m.

Food and Feeding. In Junín feeds most of the year mainly from the flowers of *Chusquea spinosa* shrubs, but in the puna of Huancavelica exploits cactus flowers. Opportunistically trap-lines, searching for red flowers of *Cajophora*, *Castilleja* and *Puya*, and occasionally visits flowering *Cassia* and *Eucalyptus*. Hawks for insects high up in the air.

Breeding. Feb-Mar. Nests in sheltered places on rocks and under edge of farmhouse roofs. Large cup-shaped nest glued to the substrate. Clutch size 2. Probably first breeds in second year. No further information.

Movements. Although the species stays all year on the Junín Altiplano, it has been suggested that it leaves the puna in Huancavelica when cacti are not flowering.

Status and Conservation. Not globally threatened, CITES II. Restricted-range species: present in Junín Puna EBA. Generally fairly common, and abundant in hills around L. Junín, inside Junín and Huayllay National Reserves, and at many sites in Huancavelica. The puna slope habitat is not under particular threat in this region.

Bibliography. Carpenter (1976), Fjeldså (1983, 1992), Fjeldså & Kessler (1996), Fjeldså & Krabbe (1990), Koepeke (1970), Meyer de Schauensee (1982), Morrison (1939), Olrog (1968), Parker *et al.* (1982), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Zimmer (1951a).

211. Wedge-tailed Hillstar

Oreotrochilus adela

French: Colibri adèle

German: Rotflanken-Andenkolibri

Spanish: Colibrí de Cochabamba

Taxonomy. *Trochilus Adela* d'Orbigny and Lafresnaye, 1838, Chuquisaca, Bolivia.

Monotypic.

Distribution. Montane basins and pre-puna of S Bolivia (S La Paz to Potosí and Chuquisaca); also reported from Cota-cota (N La Paz).

Descriptive notes. 11-13 cm; 7.4-8.3 g. Bill slightly decurved, black. Upperparts grey-brown, faintly bronzed. Male with gorget glittering vivid green, underparts chestnut with bold black central area; tail blue-black with cinnamon inner webs of all except central feathers. Female has throat white with greyish and green spots, below pale rufous; tail with white feather tips. Immature resembles adult female.

Habitat. Mainly in semi-arid to temporarily humid areas at 2600-4000 m with dispersed mesophytic shrubs; often in gullies with *Polylepis* trees with many parasitic loranthaceans (*Tristerix*) and *Barnadesia* thickets. May even be found in degraded habitats with *Dodonaea* bushes, provided that scattered columnar cacti and some taller bushes are present.

Food and Feeding. Forages for nectar at flowers of *Barnadesia*, *Mutisia*, Lorantheaceae mistletoes, *Puya* and columnar cacti. Also takes some insects.

Breeding. Eggs reported from Nov, juveniles from Feb and Jun. Large cup-nest glued to rock surface. No further information.

Movements. Probably some individual dispersal or local movements, but not well known.

Status and Conservation. Not globally threatened, CITES II. Currently considered Near-threatened. Restricted-range species: present in High Andes of Bolivia and Argentina EBA. Generally rather uncommon, but apparently able to survive in areas that are severely degraded by burning and overgrazing, as long as some bushy patches remain in ravines. Because of the dense human population in its range, adequate protected areas need to be established in order to cover core habitat for this species.

Bibliography. Álvarez & Blendinger (1995), Barnett *et al.* (1998), Bond & Meyer de Schauensee (1943), Carpenter (1976), Fjeldså (1992), Fjeldså & Kessler (1996), Fjeldså & Krabbe (1990), Meyer de Schauensee (1982), Olrog (1968), Remsen & Traylor (1989), Sagot (1998a), Schmitt *et al.* (1997), Stattersfield *et al.* (1998), Stotz *et al.* (1996).

Genus LAFRESNAYA Bonaparte, 1850

212. Mountain Velvetbreast

Lafresnaya lafresnayi

French: Colibri de Lafresnaye

German: Samtbauchkolibri

Spanish: Colibrí Aterciopelado

Other common names: Velvetbreast

Taxonomy. *Trochilus La Fresnaye*, Boissonneau, 1840, Bogotá, Colombia.

Genus apparently close to *Oreotrochilus*, based on behaviour and external morphology. Population from Páramo de Tamá (extreme W Venezuela) often separated as race *tamae*; another in N Peru as race *orestes*, but probably better considered synonymous with *rectirostris*. "*Coeligena lawrencei*" is probably a hybrid of present species and *Coeligena torquata*. Five subspecies recognized.

Subspecies and Distribution.

L. l. liriopae Bangs, 1910 - Santa Marta Mts (NE Colombia).

L. l. greenewalti Phelps & Phelps, Jr., 1961 - W Venezuela (NE Táchira, Mérida, S Trujillo).

L. l. lafresnayi (Boissonneau, 1840) - extreme W Venezuela (Páramo de Tamá in S Táchira) and E & C Andes of Colombia.

L. l. saul (DeLatre & Bourcier, 1846) - Andes of SW Colombia, Ecuador and N Peru.

L. l. rectirostris Berlepsch & Stolzmann, 1902 - N & C Peru.

Descriptive notes. 11.5-12 cm (including bill of 3 cm); 4.5-6.3 g. Male has long, thin, decurved black bill; upperparts grass green; white postocular spot, throat and breast iridescent emerald green, belly velvet black, central rectrices bronze-green, rest buff (nominate race) or whitish (all other races), tipped black. Female similar to male but with underparts buff (nominate race) or white (all other races) with iridescent green discs. Immature similar to female but head feathers have brownish fringes; immature male separable from immature female by black belly, but otherwise similar. Race *liriopae* similar to nominate but central

pair of tail feathers coppery green, contrasting with the back; *greenewalti* paler and more yellowish-green overall; *saul* has outer rectrices pure white, tipped greenish-bronze; *rectirostris* has broad black band on tips of rectrices.

Habitat. Borders of humid montane forest and shrubby slopes from 1900 to 3400 m. Less common inside the forest. Forages at low levels, 0.5-3 m. Most numerous at 2000-2800 m.

Food and Feeding. Nectar of flowering *Centropogon*, *Castilleja*, *Siphocampylus*, *Salvia*, Lorantheaceae, Ericaceae and Gesneriaceae. Male occupies nectar-rich territories, female trap-lines between dispersed flower stands. Arthropods are caught in the air by hawking or gleaned from plant surfaces.

Breeding. Apparently during most of the year; Santa Marta, N Colombia, Jan-Mar; C Andes, S Colombia, Jul-Sept; W Colombia, Sept; NE Ecuador, Jan-Feb. Bulky cup-shaped nest of moss,

lichen and cobweb is built in vegetation covering steep rocks or roadbanks, sometimes on tree trunks at c. 1-3 m above ground. Clutch size 2; incubation 16-19 days, by female; chick darkish with sparse grey dorsal down; fledging period 23-26 days.

Movements. Marked seasonal movements to higher altitudes, in sub-*páramo* and *páramo*.

Status and Conservation. Not globally threatened. CITES II. Common in the Santa Marta Mts; in the Andes less numerous and patchily distributed. In Ecuador, occurs in several protected areas

such as Paschoa Forest Reserve, Las Cajas National Recreation Area and North Podocarpus National Park.

Bibliography. Baez *et al.* (1997), Berlioz (1932d), Best *et al.* (1997), Bloch *et al.* (1991), Butler (1979), Fjeldså & Krabbe (1990), Hilty & Brown (1986), Meyer de Schauensee & Phelps (1978), Parker *et al.* (1982), Phelps & Phelps (1961), Snow & Snow (1980), Stotz *et al.* (1996), Vélez & Velázquez (1998), Williams & Tobias (1994), Zimmer (1930, 1951b).

inches 3
cm 8

Genus *COELIGENA* Lesson, 1832

213. Bronzy Inca

Coeligena coeligena

French: Inca céleste **German:** Bronzeandenkolibri **Spanish:** Inca Bronceado

Taxonomy. *Ornismya coeligena* Lesson, 1832. Mexico; error = Venezuela. Proposed race *zuloagae*, known only from type specimen from Falcón (NW Venezuela), probably represents individual variation of nominate; more study required. "*C. purpurea*", from Popayán (SC Colombia), may be hybrid of present species and *C. prunellei*; alternatively, might be a dark variety of *C. wilsoni*. Six subspecies recognized.

Subspecies and Distribution.

C. c. coeligena (Lesson, 1832) - N Venezuela (Lara E to Miranda).
C. c. zuliana Phelps & Phelps, Jr., 1953 - Sierra de Perijá, on Venezuela-Colombia border.
C. c. columbiana (Elliott, 1876) - Andes of NW Venezuela (Barinas, Lara, Táchira) and E & C Andes of Colombia.
C. c. ferruginea (Chapman, 1917) - C & W Andes of Colombia.
C. c. obscura (Berlepsch & Stolzmann, 1902) - Andes of extreme S Colombia, Ecuador and Peru.
C. c. boliviana (Gould, 1861) - Andes of C & SE Bolivia.

Descriptive notes. c. 14 cm; male c. 7.3 g, female c. 6.2 g. Male has long, straight, black bill, lower mandible often yellowish at base, head and upperparts dark bronzy-brown with distinct maroon sheen, becoming greenish on lower back; postocular spot white; throat and chest spotted white and streaked dusky grey, rest of underparts rufous brown, undertail-coverts rufous, edged cinnamon; tail forked, bronze. Female similar to male but has longer bill; tail less forked. Immature resembles adult female. Race *zuliana* has slightly more greenish plumage, less bronzy crown and upperparts; *columbiana* is smallest of all races, plumage

generally more olive; *ferruginea* similar to nominate but with throat less extensively white, and underparts more strongly washed tawny; *obscura* has darkest plumage, back more blackish, throat more greyish than white, large dark speckles; *boliviana* similar to nominate but discs on crown are dark green, tail bronzy blackish-purple, darker than in all other races.

Habitat. Edges of humid pre-montane forest, at 1500-2600 m. Sometimes in open terrain with scattered trees and in coffee plantations. Forages at periphery of vegetation.

Food and Feeding. Nectar of flowering *Fuchsia*, *Bomarea*, *Cavendishia*, *Centropogon*, *Heliconia* and *Siphocampylus*. Arthropods are caught by hawking and hover-gleaning. Feeds by trap-lining in lower to middle strata within and at edge of forest. Seldom seen in canopy of flowering trees where occasionally defends feeding territories.

Breeding. Nov-Mar. Nest cup-shaped, in understorey 1-1.5 m above ground, well hidden in fork of shrub, built of moss and plant fibres. Clutch size 2; incubation 15-16 days, by female; chick blackish with two dorsal rows of buffy down; fledging at 22-24 days.

Movements. Seasonal movements occur but not well understood, perhaps follows breeding season.

Status and Conservation. Not globally threatened. CITES II. Locally common. Although original habitat suffers from deforestation, species is not seriously affected because it accepts man-made habitats, like coffee plantations and similarly disturbed areas. Range includes several protected areas such as Henri Pittier National Park (Venezuela) and Cueva de los Guácharos National Park (Colombia). Imports for wild-bird trade in Europe during recent decades had no significant negative effect on populations.

Bibliography. Best *et al.* (1997), Bond & Meyer de Schauensee (1943), Butler (1979), Chapman (1917), Davies *et al.* (1994), Fjeldsá & Krabbe (1989, 1990), Hilty & Brown (1986), Meyer de Schauensee & Phelps (1978), Miller (1963), Olivares (1969), Olrog (1963c), Parker *et al.* (1982), Phelps & Phelps (1953), Remsen & Traylor (1989), Ridgely & Gaulin (1980), Schuchmann (1975b, 1978b, 1980d, 1989), Stotz *et al.* (1996), Zimmer (1951a).

214. Brown Inca

Coeligena wilsoni

French: Inca brun **German:** Brauner Andenkolibri **Spanish:** Inca Pardo

Taxonomy. *Trochilus Wilsoni* DeLatre and Bourcier, 1846. Juntas near Buenaventura, Colombia. Relationships uncertain within the complex containing present species, *C. prunellei*, *C. torquata* and *C. inca*; further studies needed. Forms a superspecies with *C. prunellei*. "*C. purpurea*", from Popayán (SC Colombia), might be a dark variety of present species; alternatively, may be hybrid *C. coeligena* x *C. prunellei*. Monotypic.

Distribution. Pacific slope of Andes of W & SW Colombia to W Ecuador.

Descriptive notes. c. 11-13 cm; male c. 6.9 g, female c. 6.5 g. Male has long, straight, black bill; upperparts reddish-bronze, similar to *C. coeligena*, becoming more greenish-olive especially on lower back; white postocular spot; underparts dull brown, amethyst throat patch, white patch on each side of breast; tail bronzy, forked. Female similar to male but has longer bill and smaller throat patch, tail less forked. Immature resembles female.

Habitat. Humid montane cloudforest at elevations of 700-1900 m, occasionally up to 2400 m.

Food and Feeding. Feeds on nectar of flowering epiphytic Ericads such as *Psammisia*, *Satyria*, *Macleania* and *Cavendishia*, vines and *Fuchsia*. Arthropods are usually caught by gleaning from vegetation, occasionally by hawking. Feeds by trap-lining, in lower levels within thick undergrowth.

Breeding. Jan-Jun. Cup-shaped nest of moss and soft seed fibre is built in fork of young tree, 2-3 m above ground. Clutch size 2; incubation 15-16 days, by female; chick black with two dorsal rows of buffy down; fledging at 22-26 days.

Movements. Seasonal short-distance movements probably following flowering of plants; no further data available.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species; present in Chocó EBA. Uncommon to locally common. Natural habitat under threat of deforestation; no precise information available as to whether or not this species accepts man-made habitats or even lightly disturbed areas. In Colombia, present in several protected areas, e.g. La Planada and Río Nambi Reserves. Has been imported to Europe on regular basis during recent decades.

Bibliography. Best *et al.* (1997), Butler (1979), Hilty (1997), Hilty & Brown (1986), Kirwan & Marlow (1996), Meyer de Schauensee (1982), Olrog (1968), Rutgers & Norris (1972), Salaman (1996), Salaman & Mazariegos (1998b), Schuchmann (1980d), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Williams & Tobias (1994).

215. Black Inca

Coeligena prunellei

French: Inca noir **German:** Blauschulter-Andenkolibri **Spanish:** Inca Negro

Taxonomy. *Trochilus Prunellei* Bourcier, 1843. Facativa, Colombia.

Relationships uncertain within the complex containing *C. wilsoni*, present species, *C. torquata* and *C. inca*; further studies needed. Forms a superspecies with *C. wilsoni*. Taxonomic status of "*C. assimilis*" uncertain: could represent a valid race of present species or a variation; further study required. "*C. purpurea*", from Popayán (SC Colombia), may be hybrid of present species and *C. coeligena*; alternatively, might be a dark variety of *C. wilsoni*. Monotypic.

Distribution. NC Colombia on W slope of C Andes (Quindío) and in E Andes (SE Santander, W Boyacá, W Cundinamarca).

Descriptive notes. c. 13.5 cm; 6.6-7 g. Male has long, straight, black bill, legs pale flesh-coloured; almost entire plumage purplish-black; throat patch small, greenish-blue; broken collar white, on both sides of breast; shoulders metallic blue; postocular spot white; undertail-coverts edged white, tail forked, black. Female similar to male, but has longer bill and less extensive blue on shoulders. Immature resembles female but lacks blue throat patch.

Habitat. Humid montane forest, primarily oak forest (*Quercus humboldtii*, *Trigonobalanus excelsa*) at 1000-2800 m; sometimes occurs in open country and along rivers in gallery forest.

Food and Feeding. Feeds on nectar of mainly pendent flowers with long corollas like *Aetanthus*, *Aphelandra*, *Burmeistera globosa*, *Fuchsia*, *Huileaea macrocarpa*, *Macrocarpaea*, *Palicourea demissa*, *P. vagans*, *Posoqueria*, *Psammisia falcata*, *Tilandsia turneri* and *Thibaudia rigidiflora*. Gleans and hawks for arthropods. Feeds by trap-lining from lower middle strata to canopy; lower in disturbed areas like clearings, parks and forest edge. Dominates other hummingbirds such as *Boissonneaua* or *Doryfera* at flowers, but rarely defends feeding territories.

Breeding. Probably May-Oct, based on gonadal condition. No further data available, nest undescribed.

Movements. No information available.

Status and Conservation. VULNERABLE. CITES II. Restricted-range species; present in Colombian East Andes EBA. Rare to locally fairly common. Recent records near Virolin indicate that it is common in this area; also in Cerro Carare (Boyacá), and the same holds for regular records around Laguna de Pedropalo. Major threats are destruction of humid oak forest, the main habitat, and also forest fragmentation. Although individuals are observed in relict forest patches, species is most numerous in more continuous areas of forest; accepts man-made habitats to some extent. Remaining forests are surrounded by intensive crop cultivation. The newly created Cachalú Biological Preserve, containing undisturbed *Quercus humboldtii* forest and sub-Andean rainforest, is partly aimed at offering this species additional protection.

Bibliography. Andrade & Repizzo (1994), Brooke (1988), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Fjeldsá & Krabbe (1990), Hilty (1985), Hilty & Brown (1986), King (1978/79), Meyer de Schauensee (1949), Olivares (1969), Paynter & Traylor (1981), Renjifo *et al.* (1997), Salaman & Mazariegos (1998a), Snow & Snow (1980), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Wege & Long (1995).

216. Collared Inca

Coeligena torquata

French: Inca à collier **German:** Brustband-Andenkolibri **Spanish:** Inca Acollarado
Other common names: White-cravat Hummingbird

Taxonomy. *Ornismia torquata* Boissonneau, 1840. Bogotá, Colombia.

Relationships uncertain within the complex containing *C. wilsoni*, *C. prunellei*, present species and *C. inca*; further studies needed. Forms superspecies with *C. torquata*, with which traditionally considered conspecific; however, probably best considered separate species, on the basis of differences in plumage coloration, together with disjunct distributions. "*C. traviesi*" and "*C. lawrencei*" are most likely hybrids between present species and, respectively, *C. lutetiae* and *Lafresnaya lafresnayi*. Six subspecies recognized.

Subspecies and Distribution.

C. t. conradi (Bourcier, 1847) - Andes of NW Venezuela (Trujillo, Mérida) and E Andes of Colombia.
C. t. torquata (Boissonneau, 1840) - Andes of NW Venezuela (Táchira) through Colombia and E Ecuador to N Peru.
C. t. fulgidigula (Gould, 1854) - W Andean slopes of Ecuador.

C. t. margaretae Zimmer, 1948 - Andes of N Peru (Chachapoyas).
C. t. insectivora (Tschudi, 1844) - Andes of C Peru.
C. t. eisenmanni Weske, 1985 - S Peru (Cordillera Vilcabamba).

Descriptive notes. c. 14.5 cm; male c. 7.3 g, female c. 6.6 g. Male has long, straight, black bill; head black with dark purple crown spot; upperparts blackish-green, becoming green on lower back, postocular spot white; chin and throat black with green discs, broad white collar, underparts blackish-green, undertail-coverts washed green; tail forked, inner rectrices dark golden green, others white with contrasting dark golden green tips varying in size. Female has bill longer than male; head washed green lacking purple crown spot, upperparts shining golden green; chin grey with some green discs; large white collar, belly

dark grey with some golden green discs; undertail-coverts grey-green, fringed white; tail less forked. Immature similar to adult female, head feathers with buffy fringes. Race *conradii* very distinct from all other races in that male has no black on head, entire plumage shining grass green, white collar most extensive, tail more greenish, less bronzy, outer primaries edged rufous, female has throat rufous with some green discs; male of race *fulgidigula* similar to nominate but with crown bluer, less violet, upperparts slightly lighter blackish-green, throat patch large and shining turquoise green, collar narrower, belly green, female has upperparts glittering golden green, throat with green discs, collar narrow, belly dark grey with more green discs than in nominate; *margaretae* male has two spots on crown separated by a black line, front spot small and bluish, hind spot greenish, mantle more blackish, throat light and greener than in *fulgidigula* and nominate, female is similar to that of nominate and *fulgidigula*; *insectivora* male lacks the frontal patch, crown spot light green, mantle green with black, female similar to nominate; male of race *eisenmanni* has head black with green crown spot, upperparts and underparts shining green, uppertail-coverts shining coppery, central pair of rectrices bronzy-green, remaining rectrices white tipped bronzy-green, female green with some black on sides of head, throat rufous.

Habitat. Understorey to lower canopy of humid montane cloudforest, forest borders and occasionally in sub-*páramo*, mainly at 2200–3000 m, sometimes lower at 1500 m. Replaced ecologically at lower altitude by *C. coeligena*, though both species can occur sympatrically.

Food and Feeding. Nectar of flowering *Bomarea carderi*, *Cavendishia pubescens*, *C. guatapeensis*, *Fuchsia*, *Loasa*, *Macrocapaea*, *Palicourea demissa*, *P. vagrans* and *Vriesea*. Feeds by trap-lining in understorey to lower middle strata, sometimes in canopy, at forest edges or within dense vegetation. Where sympatric with *C. prunellei* it is subordinate to that species and is chased away from flowers. Catches arthropods by hawking or gleaning from foliage.

Breeding. Nov–Mar (Colombia). Cup-shaped nest hidden under ferns on rock cliffs 1.5–2 m above ground. Nest constructed of plant fibres and heavily decorated with yellowish-green moss and dead fern leaves on the outside. Clutch size 2; incubation by female. No further information.

Movements. No information available, but possibly undertakes seasonal short-distance movements and dispersal after reproduction.

Status and Conservation. Not globally threatened. CITES II. Very common throughout much of range. To date no threats have been recorded, but since its habitat, humid montane cloudforest, is under heavy threat of destruction, species could suffer in the near future. Does not seem to take to man-made habitats or otherwise disturbed areas. Large areas of its habitat are protected, such as Munchique National Park (Colombia) and Paschoa Forest Reserve and North Podocarpus National Park (Ecuador). Has been imported regularly into Europe over recent decades, but rate of importation has decreased following tightening of national and international regulations; wild-bird trade does not seem to have had a severe impact on populations.

Bibliography. Baez *et al.* (1997), Best *et al.* (1997), Bloch *et al.* (1991), Butler (1979), Davies *et al.* (1994), Fjeldså & Krabbe (1990), Hilty & Brown (1986), Kraemer & Schmitt (1991), Meyer de Schauensee & Phelps (1978), Parker *et al.* (1982), Remsen (1985), Ridgely & Gaulin (1980), Rusch (1961d), Rutgers & Norris (1972), Schuchmann (1980d), Snow & Snow (1980), Stotz *et al.* (1996), Weske (1985), Wiedenfeld (1985), Williams & Tobias (1994), Zimmer (1948, 1951a).

217. Gould's Inca

Coeligena inca

French: Inca de Gould **German:** Inkaandenkolibri **Spanish:** Inca de Gould

Taxonomy. *Bourcieria inca* Gould, 1852, Coroico, Bolivia.

Relationships uncertain within the complex containing *C. wilsoni*, *C. prunellei*, *C. torquata* and present species; further studies needed. Forms superspecies with *C. torquata*, with which traditionally considered conspecific; however, probably best considered separate species, on the basis of differences in plumage coloration, together with disjunct distributions. Race *omissa* doubtfully valid, as the characters distinguished are very weak and not constant. Two subspecies currently recognized.

Subspecies and Distribution.

C. i. omissa Zimmer, 1948 - Andes of SE Peru (Urubamba to Puno).

C. i. inca (Gould, 1852) - Andes of Bolivia (La Paz, Cochabamba).

Descriptive notes. c. 14.5 cm; 6.8–7.2 g. Male has long, straight, black bill; head black with green frontlet, postocular spot white; upperparts golden green, becoming more shiny green on lower back; uppertail-coverts golden green; throat black with some green discs; collar rufous instead of white as in *C. torquata*, belly golden green; undertail-coverts light golden green, fringed white; tail forked, central pair of rectrices bronzy-green, remainder white with bronzy-green tips. Female has longer bill than male; head black, lighter than in male with golden green discs, upperparts shining golden green; collar rufous with some

green discs on sides, lower underparts washed rufous with large golden green discs; tail less forked. Immature resembles adult female. Male *omissa* differs from nominate in bluish rather than green frontlet, back and lower underparts dark green, throat is more pronounced green; female not distinguishable from nominate.

Habitat. Understorey and lower canopy of wet montane forest, at 1600–3200 m. Forages inside forest and along trails.

Food and Feeding. Takes nectar of flowering epiphytic ericads, vines, climbers and bromeliads, mainly with long tubular pendent corollas. Insects and other arthropods are caught by hawking or gleaning. Feeds on nectar by trap-lining.

Breeding. No information available.

Movements. No information available.

Status and Conservation. Not globally threatened. CITES II. Locally common. Part of range is protected by nature reserves and national parks. No evidence available at present that species can adapt to man-made habitats.

Bibliography. Bond & Meyer de Schauensee (1943), Fjeldså & Krabbe (1989, 1990), Hinojosa *et al.* (1998), Olrog (1968), Remsen (1985), Remsen & Taylor (1989), Weske (1985), Zimmer (1948, 1951a).

218. White-tailed Starfrontlet

Coeligena phalerata

French: Inca à queue blanche **German:** Weißschwanz-Andenkolibri **Spanish:** Inca Coliblanco

Taxonomy. *Leucuria phalerata* Bangs, 1898, Macotama; error = San Miguel, Santa Marta Mts, Colombia.

Monotypic.

Distribution. Santa Marta Mts (NE Colombia).

Descriptive notes. c. 14 cm. Male has long, straight, black bill; head and crown glittering turquoise, small white postocular spot; upperparts metallic dark green; underparts emerald green with blue throat patch, white leg puffs, undertail-coverts white; tail forked, white, bronze tips disappearing with age. Female has longer bill than male, upperparts shining green, crown dusky blue-green, small white postocular spot; underparts uniform rufous cinnamon; tail less forked, bronzy with small, pale buff tips. Immature resembles adult female.

Habitat. Interior and borders of humid and wet montane forest at 1400–3700 m. Slight differences between sexes in habitat choice recorded; male prefers openings in forest interior while females outnumber males at forest borders.

Food and Feeding. Feeds on nectar of flowering *Fuchsia*, bromeliads, banana and probably of a similar range of flowers as other *Coeligena*. Arthropods are taken by gleaning or hawking. More territorial than other *Coeligena*; occasional trap-liner.

Breeding. Feb–Apr based on gonadal condition of specimens. No further information available.

Movements. No information available.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species: present in Santa Marta Mountains EBA. Generally common. This species is endemic to the Santa Marta Mts, the natural habitats of which, although largely protected, are under severe threat of deforestation. Species is not known to accept man-made habitats or even slightly disturbed areas. Urgent need for further investigation.

Bibliography. Fjeldså & Krabbe (1990), Hilty & Brown (1986), Meyer de Schauensee (1982), Norton (1975), Olrog (1968), Salaman & Mazariegos (1998a), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Todd & Carriger (1922).

219. Golden Starfrontlet

Coeligena eos

French: Inca doré **German:** Goldandenkolibri **Spanish:** Inca Alirrufo

Taxonomy. *Helianthea Eos* Gould, 1848, higher altitudes of the Sierra de Mérida, Venezuela. Probably forms a superspecies with *C. bonapartei*, *C. helianthea*, *C. lutetiae* and *C. violifer*; traditionally considered a race of *C. bonapartei*, but probably best considered a separate species on the basis of plumage characters. Monotypic.

Distribution. Andes of W Venezuela, in Trujillo, Barinas, Mérida and Táchira.

Descriptive notes. c. 14 cm; male c. 6.8 g, female c. 6.4 g. Male has long, straight, black bill, shorter than in other *Coeligena*; plumage characters are similar to *C. violifer*; head blackish-green with green frontlet, small white postocular spot, upperparts golden green becoming glittering golden on rump; throat emerald green with violet throat patch, belly yellowish-green to golden orange; dark wing with cinnamon secondaries fringed dark brown, outer primary edged rufous; undertail-coverts light cinnamon, tail forked, cinnamon tipped golden bronzy. Female has longer bill than male; greenish head, upperparts similar

to male; cinnamon buff chin with green discs; belly glittering, less golden orange; tail less forked. Immature resembles adult female.

Habitat. Cloudforest and dwarf forest, openings with scattered vegetation, sometimes near *páramo* at 1400–3200 m. Forages at periphery of vegetation, usually very low down, at 2–3 m.

Food and Feeding. Feeds on nectar of flowering *Bomarea*, *Cavendishia*, *Fuchsia*, *Macleania*, *Mutisia* and *Palicourea*. Gleans, and occasionally hawks for arthropods. Feeds by trap-lining from lower to middle strata in trees around edge of thickets.

Breeding. Jan–Mar. Nest cup-shaped, made of moss, lichens and rootlets, lined with soft plant material such as fibres of Bromeliad seeds, attached to vertical branches inside vegetation. No further information.

Movements. Possibly seasonal altitudinal dispersal after breeding and following flowering food plants.

Status and Conservation. Not globally threatened. CITES II. Range is protected by two national parks and there is at present no threat of deforestation. Species is not known to accept man-made habitats.

Bibliography. Fjeldså & Krabbe (1990), Meyer de Schauensee (1982), Meyer de Schauensee & Phelps (1978), Olrog (1968), Stattersfield *et al.* (1998).

220. Golden-bellied Starfrontlet

Coeligena bonapartei

French: Inca de Bonaparte **German:** Goldbauch-Andenkolibri **Spanish:** Inca Ventriderado
Other common names: Dusky Starfrontlet (*orina*)

Taxonomy. *Ornismia bonapartei* [sic] Boissonneau, 1840, Bogotá, Colombia. Probably forms superspecies with *C. eos*, *C. helianthea*, *C. lutetiae* and *C. violifer*; traditionally considered to include *C. eos* as race, but probably best considered separate species on the basis of plumage characters. Taxon *orina*, known from single specimen (probably an immature male), is often considered a separate species; however, it may be best considered a race of present species, or it may even represent some melanistic plumage. Three subspecies recognized.

Subspecies and Distribution.

C. b. consita Wetmore & Phelps, Jr., 1952 - Sierra de Perijá, along Colombia-Venezuela border.

C. b. bonapartei (Boissonneau, 1840) - E Andes of Colombia (Boyacá S to Bogotá).

C. b. orina Wetmore, 1953 - Páramo de Frontino in Antioquia (NC Colombia).

Descriptive notes. c. 14 cm; 6.4-6.9 g. Male has long, straight, black bill; head black with green iridescent frontlet slightly more bluish than in *C. eos*, postocular spot white; upperparts shining dark green, more golden orange on rump, uppertail-coverts dark golden bronze; throat glittering dark emerald green with iridescent violet patch, more bluish than in *C. eos*, belly golden, undertail-coverts golden bronze fringed rufous; tail forked, dark golden bronze. Female similar to male, bill longer; head green; chin and throat rufous with some green discs; underparts rufous with large green discs, golden on vent, undertail-coverts bronzy-green, largely

fringed rufous; tail less forked, golden bronze, sometimes buff on tip. Immature resembles adult female. Male of *consita* similar to nominate but has rufous band across secondaries contrasting with dusky rest of wing, tail slightly brighter golden bronze, female similar to nominate apart from rufous band on wing; male of doubtful race *orina* very dark, almost black with a weak green sheen, lacking bronzy and cinnamon, small bluish gular spot, female unknown.

Habitat. Cloudforest and dwarf forest, open terrain with scattered vegetation at 1400-3200 m.

Food and Feeding. Flowers visited for nectar include *Bomarea*, *Cavendishia*, *Fuchsia*, *Macleania*, *Mutisia* and *Pulicourea*. Hawks in the air for insects and gleans arthropods from plant surfaces. Feeds mainly by trap-lining low down on outer edges of medium to tall shrubs.

Breeding. Jan-Jul. No further information.

Movements. No information but altitudinal dispersal likely.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species: present in Cordillera de Mérida EBA and Colombian East Andes EBA. Generally common. Race *bonapartei* has a wide distribution, but *consita* and *orina* very restricted in range. Perijá Mts (*consita*) are situated on the Venezuela-Colombia border, where much illegal activity takes place, such as of new settlements. The region does not coincide with any protected areas, and numerous roads approaching Perijá Mts from Colombian territory imply further interest by people in colonizing the area and the exploitation of minerals; some parts of range are still pristine, however. All races seem to accept habitat disturbance by man to some extent.

Bibliography. Bleiweiss (1988b), Carrier (1954), Fjeldså & Krabbe (1990), Hilty (1985), Hilty & Brown (1986), Meyer de Schauensee (1982), Meyer de Schauensee & Phelps (1978), Olrog (1968), Salaman & Mazariegos (1998a), Stattersfield *et al.* (1998), Siles & Wolf (1974), Stotz *et al.* (1996), Wetmore (1953), Wetmore & Phelps (1952).

221. Blue-throated Starfrontlet

Coeligena helianthea

French: Inca porphyre **German:** Rosenbauch-Andenkolibri **Spanish:** Inca Ventrivioleta

Taxonomy. *Ornismia helianthea* Lesson, 1838, Bogotá, Colombia.

Probably forms superspecies with *C. eos*, *C. bonapartei*, *C. lutetiae* and *C. violifer*. Race *tamai* sometimes misspelt "*tamae*". Two subspecies recognized.

Subspecies and Distribution.

C. h. helianthea (Lesson, 1838) - N & E Andes of Colombia (Sierra de Perijá to Bogotá).

C. h. tamai Berlioz & Phelps, 1953 - Páramo de Tamá in Táchira (W Venezuela).

Descriptive notes. c. 13 cm; male 7.1-7.6 g, female 6.6-5 g. Male has long, straight, black bill; head black with dark green frontlet, postocular spot white, upperparts dark with slight emerald green gloss, lower back and rump dark blue with some violet; underparts dark grey with emerald

green sheen, dark iridescent violet throat patch, lower underparts shining rosy including undertail-coverts; tail forked, bronzy-black. Female similar to male, bill longer; head grey-green, upperparts golden green becoming blue-violet on rump but not as conspicuous as in male; throat rufous, breast rufous with green discs, belly rosy, undertail-coverts lighter, without rosy sheen; tail less forked, dark bronzy-black. Immature similar to adult female. Male of race *tamai* is duller, belly and undertail-coverts more bluish, less rosy; female similar to nominate.

Habitat. Cloudforest and dwarf forest, forest edge, shrubby slopes, also visits flowering gardens. Occasionally in more open terrain and in bushy sub-páramo at 1900-3300 m.

Food and Feeding. Food plants visited for nectar include *Befaria*, *Bomarea*, *Cavendishia cordifolia*, *Elleanthus*, *Fuchsia*, *Macleania*, *Macrocarpea*, *Symbolanthus* and *Tropaeolum*. Individuals have been seen taking nectar from long corollas of *Passiflora mixta* using holes pierced by White-sided Flowerpiercer (*Diglossa albilatera*) at the flower base. Insects are usually caught by gleaning from foliage, sometimes by hawking. Feeds by trap-lining in lower strata.

Breeding. May-Oct. No further information available.

Movements. Unknown, but seasonal altitudinal dispersal likely.

Status and Conservation. Not globally threatened. CITES II. Restricted-range species: present in Colombian East Andes EBA. Locally common. This species is probably more able than its congeners to accept disturbed areas and man-made habitats; not so closely tied to cloudforest as other *Coeligena* species; nevertheless, its natural habitat is under threat of deforestation.

Bibliography. Fjeldså & Krabbe (1990), Hilty & Brown (1986), Meyer de Schauensee (1982), Meyer de Schauensee & Phelps (1978), Olrog (1968), Snow & Snow (1980), Stattersfield *et al.* (1998), Stotz *et al.* (1996).
